APPENDIX I

APPENDIX I: COST ISSUES

This Appendix discusses some of the cost issues relevant to integrated solid waste management planning. It is not possible to develop a detailed cost plan for the recommendations made in the report. To do so would require obtaining present cost data from the County and the County Sanitation Districts of Los Angeles County, as well as from each of the Cities in the County.

Determining the actual cost of solid waste management is one of the most difficult tasks encountered by communities developing integrated solid waste management plans. Many costs, particularly overhead costs such as personnel management, are handled by separate departments. The amount of time allocated to management of solid waste personnel must be estimated as part of the overall cost of solid waste. In addition, divisions often share equipment, marshalling yards or supervisory personnel, or pitch in together to provide emergency services, making it difficult to identify solid waste-specific costs.

The objective in this Appendix is to get the County thinking about how to develop a coherent integrated solid waste management system and help communities control costs. The County can function in a key coordinating role. This does not mean that the County shoulders all costs or manages all facilities; it means that the County actively supports the Cities and facilitates their operations. Elaborate solid waste systems can be very costly if program components are added piecemeal. County leadership can be critical in this area through:

- preparing the County Comprehensive Plan to coordinate efforts between the various County jurisdictions or provides joint City/County-sponsored facilities;
- developing facilities that serve multiple jurisdictions (e.g., transfer stations) that, through economies of scale, keep costs down despite possible longer haul distances;
- developing County model programs, including a variable rate fee system for County-collected areas and technology demonstration programs for landfill operations (see Chapter IX.F); and

- maintaining the economic viability of existing facilities, for example, through waste transfer to the WTE facilities (Chapter IX.H) or developing a policy of purchasing supplies from recycling enterprises ("Buy Recycled") that utilize recyclables collected in Los Angeles County.

In addition to the coordinating role, the County can pioneer some innovative ways of financing solid waste management programs that also foster diversion of waste from disposal, including: enterprise fund accounting, and variable rate fees ("unit pricing"). Also discussed in this Appendix are the relative share of the solid waste dollar cost for different system components, and factors influencing costs. These two topics provide background for Report discussions.

A. ENTERPRISE FUNDS

Operating an integrated solid waste management system as an enterprise fund allows communities to track the true cost of service, and keeps the funding for services separate from the political vagaries of the government budgeting process. In an enterprise fund, all revenues and costs go to a cost center. Revenues do not go to the General Fund, debt service is not paid for by Finance, benefits by Personnel, or fuel by the Transportation Department, etc., which is often the case when solid waste is part of a jurisdiction's operation. Future post-closure costs and sinking funds are established in enterprise accounting, and it possible to tell the cost for solid waste service and charge for it -- by the ton, by the household, by the business address, etc.

B. VARIABLE RATES

Local governments need to find ways to charge the generator for the service received in order to get solid waste costs out of the General Fund. Direct billing of customers for the solid waste service received is a key component of enterprise fund accounting. These fees, plus other revenues such as from the sale of recovered materials, make up the funds used to pay costs. Generator billing should be done in a way that encourages source reduction as well as maximizes diversion. A variable rate system (also called "unit pricing") goes far to accomplish this and

is also an important part of enterprise accounting for solid waste management. Variable rate pricing has been the norm in commercial collection for years -- the generator is billed based either on the weight of the material collected by the hauler, or by the size of the waste storage container used by the generator. For the residential customer, it can mean higher costs for more waste, or lower costs for less waste and more recycling. For the commercial generator, it can mean differential fees (or no fee) for loads that can be recycled. As consumerism is applied to solid waste services, the generator will have incentive to dispose of less and to set aside more materials for recycling. An example of a variable rate fee system is provided in Appendix A, Case Study of the City of Seattle.

C. COSTS FOR SOLID WASTE SERVICES

The solid waste dollar goes to many functions, depending upon the make-up of the specific system. Shown in Figure I-1 is a pie chart, developed from data from several cities, that graphically portrays how the solid waste dollar is split up. Administrative costs for each of the components are included in each portion of the pie. As can be seen, collection-related costs comprise over 60 percent of the pie, followed by disposal at 30 percent, and lastly by processing at 8 percent. It should be noted that solid waste collection includes bulk waste and special collections (such as post-special event collections and disaster debris), while recycling collection costs include yard waste collection as well as curbside service for materials. The pie chart shows recycling-related collection costs at 20 percent -- or almost one-third of the collection expenditures. Recycling costs overall can represent over one-quarter of the way the solid waste dollar is spent.

In addition to the above service-related and direct administrative costs, a community can expend considerable funds on specialized services, such as Household Hazardous Waste (HHW) collection and public information campaigns to encourage recycling and HHW diversion. Many communities have turned to surcharges on landfill or transfer station tipping fees as a means of funding new diversion programs, particularly for programs such as HHW that have a high unit cost and do not produce revenues to help pay for the program. Monies collected through surcharges can "get lost" in the General Fund; enterprise fund accounting can keep these

resources dedicated to solid waste management programs.

D. FACTORS INFLUENCING COSTS

Trends that influence recycling and solid waste disposal costs are discussed in various Report Chapters, and are summarized here by the service component. Overall, the cost of solid waste management is rising, but offsetting trends are discussed as well.

1. Collection

Two factors are driving the cost of solid waste collection. First, obtaining high-quality recyclables from the waste stream often means curbside collection of source-separated designated materials. This adds specialized recycling collection trucks and personnel routed through the same neighborhoods as the solid waste collection packer trucks. Yard wastes are also collected through a separate route system. Bulk wastes may also be collected separately using open-bed trucks equipped with a grapple. Each additional collection system will increase the number of trucks and personnel needed to get the job done.

Second, as the solid waste management system has evolved, the equipment industry has been evolving along with it. Automated collection equipment allows a single driver to complete a route, rather than the two- or three-man crews required for traditional packer trucks. Sophisticated routing software and GIS mapping allow a jurisdiction to consolidate routes, so that as recycling collection expands, solid waste collection routes can be adjusted proportionally, and optimum routes (i.e., the most material in the least time) can be devised for each type of collection. Other equipment features, such as split packers, allow a single truck to perform double duty while on a route. These options can be used to reduce the cost of collection.

Communities are innovating to contain the costs resulting from these trends. Automated collection has been applied to recyclable materials as well as refuse. Rebanco in Seattle has utilized authomated recycling collection in 96 gallon carts and reduced the collection frequency to once per month. Guelph, Ontario is implementing wet/dry collection citywide in the city,

with a population of 80,000. This followed an extensive pilot program to establish the cost and effectiveness of the program. Because the collection function represents a majority of the solid waste management cost, efficiency in this area has the largest reduction in overall cost for the investment.

2. Transfer

Collection costs can also be contained by adding transfer station(s) to the system. As discussed in Chapter IX, transfer stations can reduce collection costs by keeping collection packer truck routes as short as possible (less than 30 miles). A transfer trailer can carry three times the amount of waste as a packer truck and rail cars can carry six times the amount. Shifting the waste to larger-capacity, more efficient transfer vehicles for transport to the disposal site reduces the number of personnel and vehicles needed.

Even though transfer operations add capital and operations costs for transfer stations and vehicles, they have the potential to significantly reduce the overall cost. The reduction in the non-productive time for the route collection trucks has a double pay-off. First, the cost per collection route is reduced and second, the route collection trucks can collect from additional routes. This lowers the investment in trucks and crews.

3. Solid Waste Disposal

Class III Sanitary Landfills are still the primary method of managing solid waste in Los Angeles County. The cost of landfill disposal is a political issue as well as a technical one. The true cost of local landfill disposal is not reflected in $20.00 per ton tipping fees. Some long-term costs of landfill disposal can be deferred (rather than paid out of tipping fees), particularly closure, post-closure, and Title V Remediation Funds, plus, for existing landfills, the cost of the site may have already been paid for and does not reflect current land values. However, a jurisdiction may choose to keep landfill prices low in order to keep waste from leaving to lower-cost disposal sites in order to maintain cash flow at the landfill, or (as in the

case of Orange or Riverside Counties) may reduce the price to attract waste from outside the jurisdiction and thus increase cash flow in the short term.

The actual cost of landfill disposal is driven by the cost of the land, pre-development costs for planning and permitting, plus the construction and operation costs of the facility over its life. The U.S. EPA promulgated new rules for landfill management on October 9, 1991. These rules, as subsequently adopted by the State of California, set standards for:

- Location. Includes limits on proximity to airports, 100-year floodplains, wetlands, fault areas, seismic impact areas, and unstable areas.
- Design. Requires composite liner and leachate collection systems to maintain less than 30-cm depth of leachate over liner. Liner systems combine compacted clay and synthetic membranes. Leachate collection piping is sandwiched in a porous layer between liners.
- Operations. Requires exclusion of Hazardous Wastes and bulk or uncontainerized liquid wastes, daily cover and control of disease vectors, methane gas monitoring and control and other air emissions control (i.e., no open burning), access restrictions to prevent illegal dumping, control of precipitation run-on and runoff, and recordkeeping for groundwater monitoring, methane gas, inspection reports, and closure/post-closure plans. No discharges to surface water are permitted.
- Groundwater Monitoring. Monitoring wells required within compliance area. Testing required for 62 pollutants (15 heavy metals and 47 volatile organic chemicals). If pollutants exceed background levels, testing must be conducted for another 245 hazardous inorganic and organic constituents. If specified levels of pollutants found, a corrective action procedure must be initiated.
- Closure and Care. Written closure plan required. Closure include a cap designed to minimize infiltration and erosion, including infiltration layer minimum of 18 inches and permeability no greater than $1x10^{-5}$ cm/sec of material. Care of the facility required for 30 years after closure, including regular inspections for cap integrity and well monitoring.
- Financial Assurance. Must provide detailed estimates of costs for closure and post-closure and to perform corrective action as required; must provide an acceptable mechanism to guarantee funding for these future activities.

In addition to the cost of the modern sanitary landfill, the State of California requires landfills to fund Article V Remediation Costs. Article V regulations require establishment of a fund to cover potential remediation of contaminated groundwater caused by landfills.

The impact of these rules has been to increase the cost per acre of constructing landfills; this, in turn, has resulted in a trend toward development of very large landfills that can keep costs down through the larger volume of waste that can be disposed of at the site. Given the size of these new landfills, there is a parallel trend toward developing new facilities in remote areas with rail or highway access where land is cheaper and large tracts available.

4. Processing

Through the 1970s and 1980s, transformation, or waste-to-energy, facilities were seen as a preferred alternative to increasingly scarce and costly landfill disposal. Facilities financed and built during that period have tip fees in the $30.00 per ton range. As a result of changes in tax law as well as increased air pollution control requirements, tip fees for new facilities would be close to $100.00 per ton.

Trends in recycling markets are discussed in detail in Chapter VII, Section B. There is a present downturn in markets following on the heels of a rapid expansion. As in the case of other commodities, market prices and opportunities for recovered materials will fluctuate; however, it is expected that markets will remain strong as a result of new final market and export market development. The processing costs of materials recovery facilities (MRF) vary among communities and average $50 per ton according to a recent NSWMA study. This includes both the capital costs and the operations and maintenance costs. Revenues from the sale of materials can off-set these costs, depending on the markets.

Unlike other recyclable materials, the markets for yard waste compost products have yet to expand. Processors are producing good material; the problem lies more in learning to present the product in a manner acceptable to the potential major markets (farmers, horticultural firms, etc.). These markets have specific needs and require a proven product. The specifications for

compost products derived from waste materials need to reflect the traditional soil amendments used by these markets (e.g., peat moss), so that the user can understand how the compost can be applied to their needs.

APPENDIX J

APPENDIX J: RECYCLING MARKETS

There are two types of markets available for all classes of recyclable materials: intermediate and final markets. The category of intermediate markets includes processors of scrap material and brokers of recyclable materials. Final markets (also called end-users) encompass the utilization of materials in the manufacture of new products in industrial plants or mills. Final markets are the last step in the recycling process. As described below, there is a lot of overlap in the functions performed by these markets.

Materials recovered from the municipal solid waste stream need upgrading in order to be marketed as raw materials to manufacturing industries. This upgrade processing step is usually carried out by an intermediate at the local level. Intermediate markets include scrap processors, materials recovery facilities (MRFs) and brokers. Materials recovery facilities may be publicly or privately owned, and generally accept source separated recyclables collected from households through drop-off or curbside collection programs. A scrap processor generally purchases a wide variety of scrap materials from industrial, commercial, and private sources. These two types of processing facilities are collectively referred to as scrap processors in this discussion. When a processor has enough of a particular material, the material is processed to final market specifications and then is transported to market. By contrast, a scrap broker arranges the final market destination of the processed goods -- a scrap broker may never see the material that is bought and sold. A scrap processor may serve as both processor and broker. The materials upgrade is but one service that the intermediate markets provide; they may also furnish storage containers, pickup for filled containers, and provide delivery of processed materials to the final market. The cost of these intermediate services is included in the price that is charged to the final market for the goods.

The final market manufactures products from the purchased recyclable materials. Usually a final market will accept only one type of material, but some final markets are now purchasing multiple materials -- processing some for their own use and acting as intermediate markets for others. Final markets generally pay higher prices for recyclable materials than do intermediate markets because final markets often rely on intermediate markets to process needed materials

for conformity to higher standards of acceptability. Although one cannot overlook the services that the intermediate market can provide, the price paid for goods by the final market is often sufficiently higher than that paid by the intermediate market to warrant bypassing the latter and selling recyclables directly to the final market. Also, in some situations, final markets are more easily accessed than intermediate markets.

1. Specifications and Agreements

Each material marketed or sold has a description or specification so that the buyer knows what is to be received. While many markets or firms have their own specifications, industry groups such as the Institute of Scrap Recycling Industries (ISRI) publish specifications that are widely accepted. Specifications address issues such as (1) allowable levels of contaminants, (2) moisture content, and (3) shipping preparation (for example, baled with a specific density). Specifications, when utilized in good faith, allow both the buyer and seller to agree on the quality of the commodity without a detailed inspection of every shipment.

The development of specifications for recovered materials has paralleled the expansion of the recycling industry. Secondary or recovered materials have grown into major domestic and international trade elements. This growth makes it impractical, if not impossible, for buyer and seller to do business on a personal basis. In the last 20 years, the amount of secondary paper consumed has doubled, resulting in more paper recovered in 1993 than was landfilled. The volume of market purchases and the standardization of these purchases, through specifications and contracts, has routinized transactions. This maturation of the secondary materials market encouraged the Chicago Board of Trade to establish trading in 1995 of recovered materials in a manner similar to virgin materials commodity trading. At the same time, procedures and protocols to deal with discrepancies in weight, quality and schedule have developed. ISRI and the Chicago Board of Trade through the American Arbitration Association, offer arbitration services to resolve disputes, as do other entities.

To avoid the fluctuations of commodities markets and the costs of small lot trading, many communities or their private recycler enter into contracts for the sale of materials over several

years. The terms of these agreements vary from one to twenty years; however, five-year contracts are common. When a contract requires one party to construct a facility to process material (such as a publicly-procured materials recovery facility), the contract term is tied to the facility life or amortization period, usually 15 to 20 years.

The price in these long-term contracts is usually adjusted using one of the recognized publishers of price data. *Official Board Markets* and *Recycling Times* are two major publishers of price data. In the last several years, the number of materials recovered from MSW quoted in these publications have grown along with the markets.

2. Processing Facilities

Whether source separated or not, material collected from waste generators needs to be processed to meet market specifications. The functions a processing facility performs are: (1) receiving, (2) storage, (3) separation, (4) cleaning, (5) size reduction, (6) densification, and (7) shipping preparation. These functions usually are contained in an industrial/warehouse type of building and include both mechanical and manual techniques. The choice of processing depends upon: materials processed, amount of material, and specifications or requirements of the markets.

The sponsorship, ownership, and operation of processing facilities can be either public or private, depending upon community situations. Prior to the recent push for recycling, processing was primarily done by private firms in the traditional secondary materials industry. These firms performed the processing necessary to prepare materials such as glass, paper, aluminum, and steel for use by industry.

When the aluminum can was introduced as a beverage container almost 20 years ago, the aluminum industry made a commitment to recycle these cans. The industry built a separate infrastructure, including: (1) collection points, (2) trucks, (3) processing facilities and (4) smelter modifications. This infrastructure cost of millions of dollars, and resulted in a current recycling rate of 65 percent.

Traditional scrap processors and the aluminum can recycling industry are only a part of the overall recycling business. The infrastructure necessary to recycle greater quantities and types of materials will require billions of dollars of investment. Processing facilities for 50 percent of the solid waste generated in Los Angeles County in 1994 (not counting yard waste) would process approximately seven million tons of material. A facility processing materials at the rate of 200 tons per day would cost about $2 to $8 million in the Los Angeles region. To have sufficient capacity using 200 TPD plants operating six days per week, 112 plants would be required. This requirement, based upon the $6 million capital cost, would involve an investment of $225 to $900 million. This is a lot of recycling infrastructure; some of which has been constructed. Sufficient capacity does not yet exist in Los Angeles County.

In addition to general processing facilities, infrastructure investment is needed for each of the recovered materials discussed below.

3. Recyclable Materials

a. Paper

Five types of paper are considered in this section: (1) old newsprint (ONP), (2) old corrugated containers (OCC), (3) printing and office paper (POP), (4) old magazines (OMG) and (5) mixed papers.

According to the American Forest & Paper Association, in 1995 more than 42 million tons of paper were recovered in the United States, with almost 33 million tons of that total recycled into new products in the U.S. Another 10 million tons was exported. Recovery has risen every year since 1985, doubling in this decade.

The major source of ONP is individual homes. ONP is used primarily in the manufacture of newsprint and paperboard. These represent 34 and 22 percent demand respectively. A small percentage of ONP is used in making tissue, cellulose insulation, and other products. Seventeen percent of ONP is exported. Demand has slackened in the last six

months due to high inventories and lower exports. A level period is expected in the immediate future.

The majority of old corrugated cardboard (OCC) ends its useful life at retail, wholesale, and industrial establishments, with a lesser portion discarded in individual homes. OCC is the most commonly recycled paper product, with 78 percent used in the manufacture of new containerboard and paperboard products. Fifteen percent of OCC is exported.

Printing and Office Paper (POP), which has the highest value of all postconsumer paper, is generated primarily in commercial offices such as financial institutions and large insurance groups. Government offices also generate considerable amounts of POP. While POP is present in the home, it is usually generated in much smaller quantities and is difficult to separate from lower value paper, such as envelopes. Twenty-eight percent of recycled POP is used in the manufacture of tissue paper (i.e., bathroom and facial tissue, towels, and napkins), with 26 percent used for writing, duplicating, and computer papers. Twenty percent of POP is exported.

The demand for the lower grades of paper -- ONP and OCC -- has historically fluctuated widely. Because so much recycled paper is used in paperboard production and construction (i.e., wallboard and insulation), when the construction industry declines or the economy is weak, the demand for and price of low-grade paper falls. Conversely, when housing construction improves and the economy is sound, demand and prices for lower grades of paper typically are strong. Because its primary end use is in basic consumer products (e.g., writing paper and tissue) the demand and price for POP is steadier and higher than for the lower grades.

As discussed below, paper manufacturers have added pulping capacity to utilize recovered paper as feedstock. This increased capacity for utilizing recovered paper has increased demand; domestic mill consumption of recovered paper rose 8 percent in 1995. Mixed paper can be recovered from both residential and commercial generators. In the last two years, there has been a trend toward recovering mixed paper from residences. In addition, the newest technology for de-inking ONP requires the use of up to 20 percent coated papers (i.e., old magazines or OMG), which has, in turn, created a market for this type of recovered paper.

Along with the growth in paper recycling has been an investment by the paper industry in plants to process recovered paper. Currently, more than 200 paper plants in the U.S. use 100 percent recovered paper as their feedstock. Another 175 plants depend upon recovered paper for a portion of their feed. Development of pulping facilities for recovered paper feedstock has involved a multi-billion investment in industrial infrastructure to date; this investment is continuing. The prices for all grades of paper rose sharply in 1995 as the result of the demand created by these new pulping plants. These prices peaked in mid-summer, then dropped due to high inventories and poor demand. The investment in new plants will prevent demand and prices from falling to 1990 levels.

b. Glass

Glass is manufactured primarily from sand and silicon dioxide. Other materials used in glass manufacturing include sodium, soda ash, and calcium from limestone. Glass manufacturers produce three categories of products: containers, flat glass, and pressed/blown glass. Glass containers account for 70 percent of all the glass manufactured and make up approximately 90 percent of the glass in municipal solid waste (MSW). Flat glass is used mainly for windows. Pressed and blown glass includes ornamental and decorative glass and other glass products such as light bulbs. These three types of glass have different chemistries and cannot be melted together to make new products. Only container glass is pertinent to this discussion. Container glass represented approximately 3.0 percent of the waste stream in Los Angeles in 1990.

Glass containers are manufactured primarily in three colors: clear (flint), brown (amber), and green. Nationally, approximately 65 to 70 percent of all containers are flint, and roughly equal amounts (15 to 18 percent) of glass containers are amber or green. Thus, the demand for recovered flint container glass is greater than the demand for either amber or green.

The glass industry uses waste glass (known as cullet) as an alternative to raw materials. Before 1970, almost all cullet used in the manufacturing process was from "in house" sources. Since 1970, when only 24,000 tons of cullet were purchased by the glass industry, cullet use from private and municipal recycling has increased to more than one million tons annually. In

1981, the price paid for cullet was generally consistent around the country, averaging about $30 per ton. By 1983, the price rose to $40 per ton and remained steady until the latter half of 1988. Since then, the price has varied with more differences among regions and by glass color. In 1995, the prices were approximately $50 per ton for flint, $40 per ton for brown, and $20 per ton for green glass. Glass prices dropped somewhat over the course of 1995, due to lagging demand.

With today's glass-processing technology, it is possible to use nearly 100 percent cullet in glass furnaces. This increased use of cullet is advantageous because cullet melts at a lower temperature than the raw materials, allowing the glass manufacturer to save energy. Also, lower furnace temperatures prolong furnace refractory life. However, while glass container recycling has been increasing, the recycling rate for 1994 was only 37 percent.

Glass has been declining as a fraction of the waste stream due to its replacement by plastic, aluminum and other containers. Low prices, low market demand for green glass in particular, and problems with glass contamination of other recyclables during collection, coupled with stringent specifications for furnace-ready cullet caused some communities to drop glass from their recycling programs. Other communities have maintained glass recycling and are marketing a mixed broken glass for lower-value uses such as aggregate and filter sands.

c. Ferrous Metals

In recent years, the market demand for ferrous metals (i.e., steel and iron) scrap has fluctuated, but has generally been rising. However, prices have fluctuated with no real pattern. The problems in steel scrap markets are linked to the decline in U.S. steel-production capacity. According to *Phoenix Quarterly*, U.S. steel production capacity peaked in 1977 at 160 million net tons. Production capacity dropped to 110 million metric tons in the mid-1980s. The Institute of Scrap Recycling Industries (ISRI) believes several factors contributed to the elimination of U.S. steel production capacity, including an oversupply of the market by foreign government-controlled steel producers and decreased demand for steel products. Offsetting this market decline to some extent is increased application of electric furnace technology and the

"mini mill" in the U.S. These smelters use a higher percentage (up to 100 percent) steel scrap as feedstock. Also, the export market has been strong.

Most of the ferrous metal in residential MSW falls into two categories: bulky ferrous (e.g., appliances) and container ferrous (e.g., food and beverage cans). There are actually two types of steel cans in residential MSW: bi-metal cans, made of a steel body and aluminum top; and "all" steel cans. The all steel cans also have two types: "tin" cans that are steel coated with a layer of tin to retard rusting, and tin-free cans. Bi-metal cans used in beverage applications largely have been replaced by aluminum cans. In the past, container ferrous was regarded as a low-quality product, and was not a primary target for recycling programs. However, the Steel Recycling Institute recently began promoting the recyclability of bi-metal and steel cans (including aerosol and paint cans), noting that the cans may go directly into existing furnaces with no special pre-processing.

The detinning industry processes "tin" cans and other tin-plated scrap to chemically remove the tin, then selling both the tin and steel to end-user markets. In the past, this industry was a major market for ferrous cans. Today, only one detinning processor remains in the U.S. and the long-term outlook is pessimistic due to the declining use of tin.

Ferrous metals, except major appliances, represent about 3.3 percent of the Los Angeles County waste stream in 1990. Prices recorded for steel cans from January through October 1995 were steady between $63 and $65 per ton. Note that steel is traded in long tons which weigh 2,240 pounds.

Appliances and other large steel items in municipal waste are referred to as white goods. These can be shredded along with automobiles to produce a high quality scrap. The market, therefore, is the traditional scrap processor with large-scale shredding equipment. Some white goods made prior to 1979 have capacitors containing PCBs. Most scrap processors insist that these capacitors be removed prior to their acceptance at processing facilities. Additionally, chlorofluorocarbons (such as freon) used as refrigerants in some appliances need to be removed and recycled or disposed of properly, rather than vented to the atmosphere. Some jurisdictions

have contracted for removal of PCBs and chlorofluorocarbons, processing and marketing with a single contractor. When white goods are shredded along with automobiles, the resulting scrap sells for $40.00 to 60.00 per ton more than ferrous can scrap on the west coast.

d. Aluminum

Aluminum, found in a variety of mineral structures, is recovered primarily from bauxite, an ore found principally in South America, Africa, and the Caribbean. Sources of bauxite within the United States are found in Alabama, Arkansas, and Georgia. Extraction of aluminum from bauxite requires a large amount of electricity. Aluminum in municipal waste is found in several forms or alloys: food container aluminum (cans and foil); aluminum housewares (e.g., pots, pans, and appliances); extrusions (e.g., lawn furniture); and castings (e.g., auto parts and more expensive cooking equipment). Food container aluminum, particularly aluminum cans, has the highest market value because the alloy from which it is made is almost pure aluminum.

Aluminum has a high value for its weight. However, it represents only a minor fraction of MSW. The 1990 solid waste composition in Los Angeles County indicates that aluminum cans were 0.6 percent of the waste stream.

In the 1970s, the U.S. aluminum industry turned to recycling as a major source of material. According to the Aluminum Association, almost 25 percent of all the aluminum used in the United States in 1988 came from recycled aluminum. The recycling rate of aluminum cans in 1990 was 61 percent, and the rate rose to 65.4 percent in 1994. The U.S. aluminum industry, particularly corporations such as Alcoa, Reynolds Metals, Alcan, and Kaiser, strongly supports aluminum recycling and has made significant investment in recycling infrastructure over the last two decades. It is estimated that there are 10,000 individual aluminum recycling facilities in the U.S. Firms in the industry actively are seeking other aluminum alloys in addition to cans in order to increase recycling.

There have been recent variations in prices paid in the Western states by processors and end-users for aluminum used beverage containers since 1990. The drop in price between 1992

and 1995 reflects the dumping of aluminum on the world market by the Russians in an effort to gain hard currency. This highlights the impact of international events upon U.S. recycling markets. These events are both normal and unpredictable. The price at the end users peaked in January 1995 at over $1,400 per ton and dropped to approximately $1,200 on the west coast in December.

e. Plastics

There are six plastic resin types typically found in MSW: high density polyethylene (HDPE), low-density polyethylene (LDPE), polyethylene terephthalate (PET), polyvinyl chloride (PVC), polypropylene (PP), and polystyrene (PE). These and other resin types can be recycled into a variety of products, including fiberfill for pillows, sleeping bags, jackets, etc.; molded products such as tubs, bins and shower stalls; and lumber-like products for vehicle stops, park benches, dock pilings, etc.

In Los Angeles County, plastic was a small, but increasing, portion of the 1990 solid waste stream. Nationally, plastic rose from less than one percent of MSW in 1960 to 6.9 percent in 1990 by weight. By volume, plastics are a higher proportion of the waste stream, estimated at roughly. 10 percent. Because recovered plastic is a lightweight, high-volume material, it requires more storage space and has higher transportation costs than higher-density recyclable commodities. For example, two-liter PET soda bottles contain entrapped air; as a result, they take up a great amount of space (the density is 1.3 pounds per cubic foot) and are difficult to compact. Plastic that has been shredded or punctured and baled can be transported much more economically; for example, shredded PET density is 25 pounds per cubic foot. In 1990, approximately 1.2 percent of the Los Angeles County solid waste stream was composed of recoverable HDPE or PET containers. These two resins most commonly are included in recycling programs and have been increasingly recycled. PET soft drink container and HDPE natural containers were recycled at 48.6 and 25.9 percent respectively in 1994. Other plastics are recycled significantly less.

HDPE prices have fluctuated widely in the past two years, peaking in March 1995 at $0.28 per pound. The recent trend has been downward, due to rising inventories and weak worldwide demand resulting from reductions in the use of recycled HDPE in products. HDPE prices were approximately $0.12 per pound in December 1995. PET prices have risen in 1995 from about $0.08 to $0.25 per pound. PET prices have been much more stable, in major part because of demand in the Far East market and due to increased use of PET in food packaging. Poor cotton harvests have contributed to this demand (PET competes with cotton in many fiber applications).

In spite of the constraints in collecting postconsumer plastics from the residential waste stream, there is a growing interest in recycling this material for social and environmental reasons. Fueled by this trend, the opportunities to recycle plastics are increasing.

Re: Proposed Sunshine Canyon Landfill Expansion

In response to (1) the Sunshine Canyon Landfill Expansion Environmental Impact Report, and (2) BFI's application for a zoning change in connection with the landfill expansion, the following questions and comments are submitted:

Importance of Protecting Groundwater Quality

How important is it to protect groundwater resources in the area where the landfill is proposed to be sited or expanded from pollution by landfill leachate? 965

Should the people who dispose of garbage today pay the true cost of garbage disposal to protect future generations' groundwater resources from impaired use? 966

Do US EPA Subtitle D regulations require protection of groundwater resources from impaired use by landfill-derived leachate at the proposed landfill or landfill expansion site for as long as the wastes in the landfill will be a threat? 967

Adequacy of Staff Review of Submitted Materials

Exhibit 1 is an example of a list of the enclosures that have been submitted to the regulatory agency on the technical deficiencies of the proposed landfill. 968

Were these materials reviewed by the staff in connection with developing the permitting of the landfill? If not, why not?

Pollutional Characteristics of MSW Landfill Leachate

Is the staff familiar with the composition of municipal landfill leachate? 969

Please examine Exhibit 2 and indicate if you find that the information provided on the composition of MSW leachate is representative of municipal landfill leachate.

Based on the results of the studies of approximately 100 landfills shown in Exhibit 2, do small amounts of municipal landfill leachate represent a significant potential threat to pollute large amounts of groundwater? 970

Threat of the Proposed Landfill to Impair Groundwater Quality

What is the staff's understanding of how long the wastes in the proposed landfill or landfill expansion will be a threat? 971

What is the basis for any assessment that the wastes in this landfill will be a threat for less than hundreds to a thousand or more years? 972

Landfill Liner Issues

What will be the liner for the proposed landfill?
Is it a minimum Subtitle D single composite liner? 973

What is your estimate of how long a 60 mil HDPE liner (plastic sheeting) in the proposed landfill liner will function as an effective barrier to prevent leachate from passing through the liner on its way to cause groundwater pollution? 974

What is the basis for your estimate?

Do you believe the plastic liner for the proposed landfill will be able to prevent leachate from passing through it in sufficient quantities to prevent groundwater pollution by landfill leachate for as long as the wastes in the landfill will be a threat? 975

Is the staff aware that landfill liner companies only warrant the flexible membrane liners for a period of 20 years? 976

Does the staff know that this warranty is pro-rated over this period and that the landfill owner/operator must remove the wastes above the defective area so the liner can be fixed? 977

How does a landfill owner know precisely where a liner is leaking? 978

Is this warranty of significant value in protecting groundwater from pollution by landfill leachate? 979

Does this highly limited warranty reflect the fact that landfill liner companies believe the flexible membrane liners they manufacture will protect groundwaters from impaired use for as long as the wastes in the landfill will be a threat? 980

Is it your position that the plastic sheeting liner and compacted clay layer, i.e. composite liner, in the proposed landfill will be an effective barrier to prevent leachate from passing through it on its way to polluting the groundwaters underlying the landfill for as long as the wastes will be a threat? 981

Subtitle D Regulations

Is the staff familiar with the part of the US EPA's Subtitle D regulations proposed in 1988 which stated.

> *"First, even the best liner and leachate collection system will ultimately fail due to natural deterioration, and recent improvements in MSWLF (municipal solid waste landfill) containment technologies suggest that releases may be delayed by many decades at some landfills."*

Further, the US EPA in their Criteria for Municipal Solid Waste Landfills (July 1988) stated,

> *"Once the unit is closed, the bottom layer of the landfill will deteriorate over time and, consequently, will not prevent leachate transport out of the unit."* 982

US EPA, "Solid Waste Disposal Facility Criteria; Proposed Rule," Federal Register 53(168):33314-33422, 40 CFR Parts 257 and 258, US EPA, Washington, D.C., August 30 (1988a).

US EPA, "Criteria for Municipal Solid Waste Landfills, "US EPA Washington D.C., July (1988b).

Do you disagree with the US EPA's reported finding, as part of promulgating Subtitle D, that the single composite liner will eventually deteriorate and allow leachate to pass through it and thereby not be collected in the leachate collection system?

If you do not agree, what is the basis for your disagreement?

What new information has been developed that shows that plastic sheeting liners of the type that are proposed for the landfill will prevent leachate from passing through them for as long as the wastes in the landfill waste management cells will be a threat? 983

Subtitle D Landfill Design Requirements

Is the staff familiar with US EPA Solid Waste Disposal Criteria Final Rule, October 9, 1991, Subpart D (Subtitle D) requirements for groundwater quality protection §258.40 Design Criteria which requires, 984

> *"(a)(1) The design must ensure that the concentration values listed in Table 1 of this section will not be exceeded in the uppermost aquifer at the relevant point of compliance..."*

Also, the US EPA states in their Subtitle D regulations,

> *"For landfills located where ground water is currently used or reasonably expected to be used for drinking water, the performance standard requires States to prevent contamination from exceeding drinking water standards."*

Exhibit 3 presents Table 1 from the US EPA Subtitle D requirements.

Exhibit 3

"Environmental Protection Agency

NOTE TO SUBPART D: 40 CFR part 239 is reserved to establish the procedures and requirements for State compliance with RCRA section 4005(c)(1)(B).

TABLE 1

Chemical	MCL (mg/l)

1,1,1-Trichloromethane	0.2
Trchloroethylene	0.005
2,4,5-Trichlorophenoxy acetic acid	0.01
Vinyl Chloride	0.002"

Will the single composite liner specified in the permit for the proposed landfill be expected to meet Subtitle D requirements of preventing exceedances of Table 1 constituents at the point of compliance for groundwater monitoring for as long as the wastes represent a threat at all sites where a landfill could be constructed? 985

What was the technical basis used to select the spacing of the monitoring wells at the point of compliance for the proposed landfill or landfill expansion? 986

Should a site-specific evaluation be made by the landfill permitting agency to determine if a minimum Subtitle D liner would be expected to be protective of groundwater resources as required by Subtitle D at the point of compliance for groundwater monitoring for as long as the wastes in the landfill will be a threat? 987

Is the staff familiar with US EPA Subtitle D Subpart E--Ground-Water Monitoring and Corrective Action §258.51 Ground-water monitoring systems which states,

> *"(a) A ground-water monitoring system must be installed that consists of a sufficient number of wells, installed at appropriate locations and depths, to yield ground-water samples from the uppermost aquifer (as defined in §258.2) that:*
> *(2) Represent the quality of ground water passing the relevant point of compliance specified by Director of an approved State under §248.40(d) or at the waste management unit boundary in unapproved States."*

and §258.53 Ground-water sampling and analysis requirements,

> *"(c) The sampling procedures and frequency must be protective of human health and the environment."* 988

and §258.54 Detection monitoring program,

> *"(a) Detection monitoring is required at MSWLF units at all ground-water monitoring wells defined under §258.51(a)(1) and (a)(2) of this part. At a minimum, a detection monitoring program must include the monitoring for the constituents listed in appendix I to this part."*

and §258.55 Assessment monitoring program,

> *"(a) Assessment monitoring is required whenever a statistically significant increase over background has been detected for one or more of the constituents listed in the appendix I to this part or in the alternative list approved in accordance with §258.54(a)(2).*
> *(b) Within 90 days of triggering an assessment monitoring program, and annually thereafter, the owner or operator must sample and analyze the ground water for all constituents identified in appendix II to this part."?*

Do these sections of Subtitle D requirements prohibit a landfill from causing a statistically significant increase in the concentrations of constituents presented in appendices I and II of Subtitle D at the point of compliance for groundwater monitoring for a Subtitle D landfill? 989

Groundwater Monitoring

Exhibit 4 presents an example of a plan for a municipal solid waste landfill site which shows the position of monitoring wells as allowed by a California regional water quality control board. This monitoring well array is typical of that allowed by regulatory agencies permitting Subtitle D landfills throughout the US. Would this array of monitoring wells comply with Subtitle D requirements providing a sufficient number of monitoring wells which will collect samples that represent the groundwater quality passing the point of compliance? 990

Where is the point of compliance for the landfill shown in Exhibit 4? 991

What are the Subtitle D requirements with respect to the ability of the groundwater monitoring system for the proposed landfill to detect leachate-polluted groundwaters at the point of compliance? 992

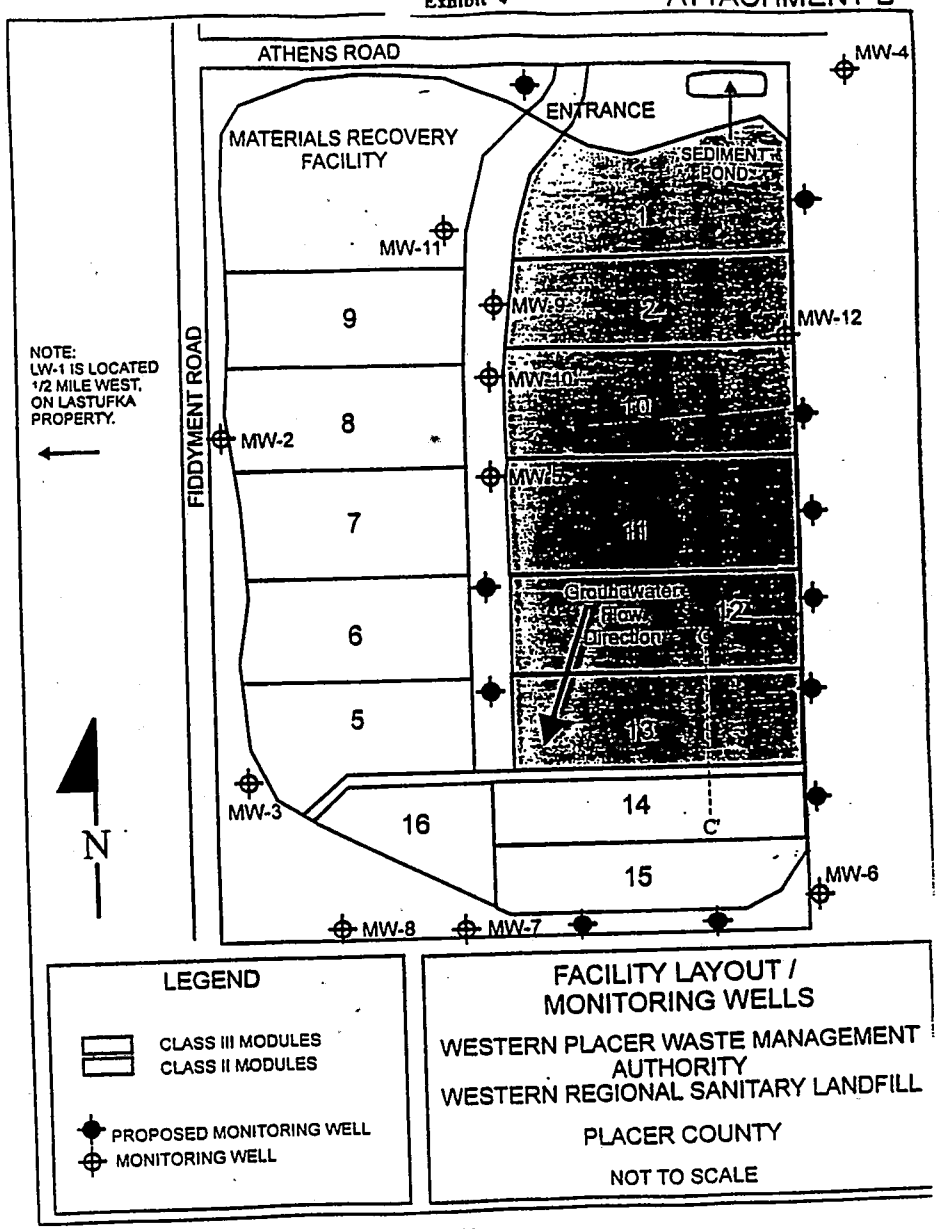
What is the spacing between the monitoring wells? 993

Should a map of the site contain a scale showing the approximate distances so that reviewers of the map can determine the spacing between the monitoring wells? 994

Assume that the map is one inch equals 100 feet. Is the spacing between the monitoring wells along the downgradient edge of the waste management unit, i.e. point of compliance - hundreds of feet apart? 995

Is this typical of groundwater monitoring wells for Subtitle D landfills at the point of compliance? 996

Are there a sufficient number of monitoring wells located such that they provide assurance of earliest possible detection of leachate releases from the waste management unit? 997



How can the staff be certain that the monitoring wells spacing and location will provide assurance of detection of leachate releases from the waste management unit and thereby provide for the assurance of earliest possible detection of releases from the waste management unit? 998

Was a site-specific evaluation conducted to determine whether the proposed monitoring well spacing and location would have a high probability of detecting landfill leachate-polluted groundwaters at the point of compliance for as long as the wastes in the landfill will be a threat? 999

If not, why not?

Exhibit 4

ATTACHMENT B

Does the staff agree that a site-specific evaluation is an appropriate requirement in order to evaluate whether the groundwater monitoring system has the potential to comply with Subtitle D requirements? 1000

If not, why not?

How was the groundwater monitoring system designed for the proposed landfill or landfill expansion? 1001

Was a site specific evaluation made to ensure that the well spacing and location would detect leachate polluted groundwaters when they first reach the point of compliance? 1002

Did the staff review the paper, "A Groundwater Protection Strategy for Lined Landfills," published by Dr. G. Fred Lee and Dr. Anne Jones-Lee, in *Environmental Science and Technology*, concerning the problems of trying to monitor groundwater pollution by leakage through plastic-sheeting lined landfills? 1003

Exhibit 5 is adapted from the Parsons and Davis paper showing an array of monitoring wells along the downgradient edge of a waste management unit which displays zones of capture of these wells, indicating that the monitoring wells zones of capture should overlap in order to prevent leachate from passing between the monitoring wells and fail to be detected by them. 1004

Do you agree with Parsons and Davis' suggested approach that the zones of capture of the monitoring wells and the well spacing should be such that there is a low probability of leachate-polluted groundwaters from passing the point of compliance without being detected?

If not, why not?

Exhibit 6 is a figure developed by Dr. John Cherry of the University of Waterloo from his 1990 paper which indicates that lined landfills produce finger plumes of leachate of a few meters width at the point of compliance for groundwater monitoring. 1005

Does the staff agree that Dr. Cherry has properly assessed this situation?

If not, why not?

What are the zones of capture of the groundwater monitoring wells that the staff has proposed for use at the proposed landfill? 1006

Exhibit 5

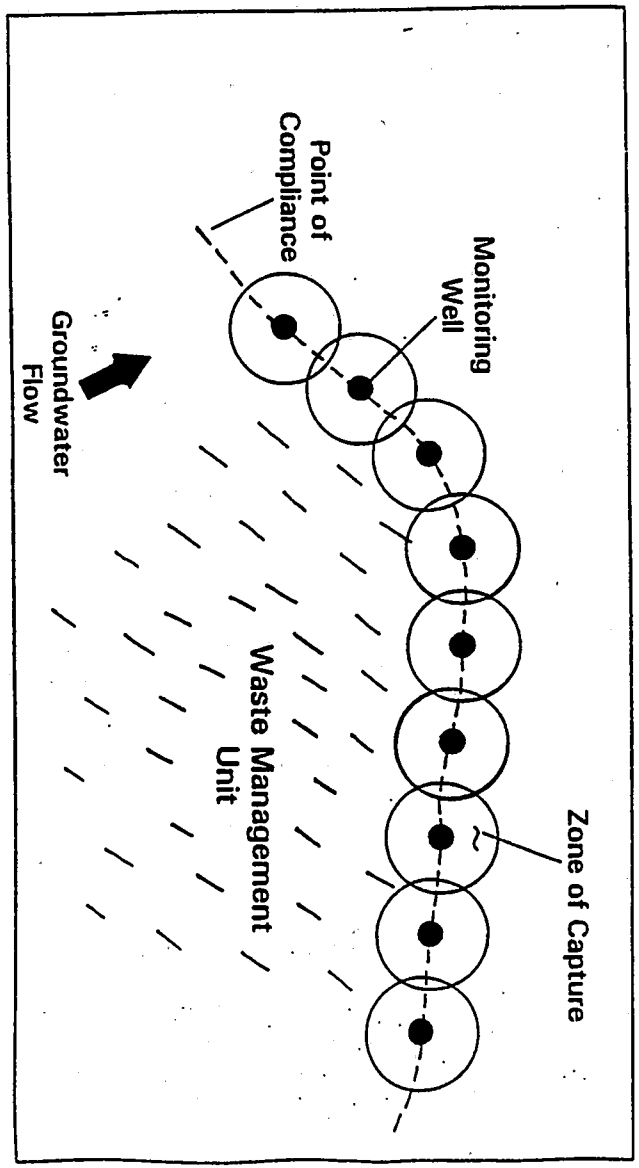


Figure 3. Zones of Capture of Standard Monitoring Wells Must Overlap to Detect Leakage from Lined Landfills (After Parsons and Davis, 1992)

Figure 2. Pattern of Landfill Leakage - Groundwater Contamination from Lined Landfills (After Cherry, 1990)

Exhibit 6

Is there a high probability that with the proposed monitoring well spacing of hundreds of feet apart and zones of capture of the monitoring wells of about one foot on each side, that leachate-polluted groundwaters that occur from leaks near the downgradient edge of the waste management unit, could pass by the point of compliance and not be detected by the monitoring well array that the staff have proposed? **1007**

Does the monitoring well array proposed by the staff for the proposed landfill provide assurance of the earliest possible detection of releases from the waste management unit? **1008**

Is there significant probability that the concentrations of the constituents listed in Table 1 (Exhibit 3) will be exceeded in the groundwaters at the point of compliance for groundwater monitoring for the proposed landfill? **1009**

If not, why not?

Should the staff/board be proactive in groundwater quality protection, or must pollution occur before the regulatory agency will act to protect groundwater resources? **1010**

Are there locations where a site-specific evaluation would show that a minimum Subtitle D landfill should not be constructed at that location because,

- the liner system will not prevent leachate from leaving the landfill and entering the groundwater system underlying the landfill for as long as the wastes represent a threat; **1011**
- the proposed groundwater monitoring system does not have a high reliability of complying with Subtitle D requirements of *a sufficient number of wells to yield ground-water samples from the uppermost aquifer that represent the quality of ground water passing the relevant point of compliance*?

Should the implementation of Subtitle D requirements of groundwater quality protection require a site-specific evaluation of the expected performance of the landfill containment system components (liner and cover) and groundwater monitoring system reliability (monitoring well spacing and zones of capture) to protect *"human health and the environment"* for as long as the wastes in the landfill will be a threat? **1012**

Could pollution-impaired use of groundwaters occur by proposed MSW landfill leachate-derived constituents that are not on US EPA Subtitle D Table 1 and appendices I and II lists? **1013**

Is the staff familiar that a large number of unregulated chemicals (unconventional pollutants) are present in municipal landfill leachate? **1014**

Could there be hazardous or otherwise deleterious chemicals in the unregulated chemicals in leachate that do not now have drinking water MCLs? **1015**

Is it appropriate to assume, as the US EPA is doing in their Subtitle D regulations, that because all drinking water MCLs are met as set forth in Table 1 that a groundwater polluted by landfill leachate is safe to consume considering the presence of unregulated hazardous or otherwise deleterious chemicals in MSW leachate? 1016

Post-Closure Care Period

1017

Does Subtitle D only limit groundwater protection to 30 years after closure of a landfill?

Are you familiar with Subtitle D, Subpart F Closure and Post-Closure Care requirements which state that,

1018

"§258.61 Post-closure care requirements.

(b) The length of the post-closure care period may be:

(2) Increased by the Director of an approved State if the Director of an approved State determines that the lengthened period is necessary to protect human health and the environment."

Will the wastes in a Subtitle D "dry tomb" landfill be a threat after the landfill has been closed for 30 years?

1019

If no, what will happen to the heavy metals, inorganic salts and persistent organics that are present in the wastes that will cause them not to be a threat?

Will they still be available to be leached from the wastes and, for some of the organics, produce landfill gas? 1020

Given that the wastes after a 30-year post-closure period will still be a threat to cause groundwater pollution through leachate generation and develop landfill gas, does the staff believe that the Board will allow the landfill owner/operator to no longer maintain and to continue to provide post-closure care required by Subtitle D at the proposed landfill? 1021

Since wastes will be a threat forever, will post-closure care be required forever? 1022

Are Subtitle D landfills significantly better than the unlined landfills with respect to their ultimate protection provided for groundwater quality? 1023

If so, how?

Is it better to postpone groundwater pollution so future generations will have to address it rather than requiring that those who generate the wastes address the problems associated with the landfill during the time that the wastes are generated? 1024

Subtitle D, Subpart D — Design Criteria states,

"§258.40 Design criteria

(a) New MSWLF units and lateral expansions shall be constructed:

(1) In accordance with a design approved by the Director of an approved State or as specified in §258.40(e) for unapproved States. The design must ensure that the concentration values listed in Table 1 of this section will not be exceeded in the uppermost aquifer at the relevant point of compliance, as specified by the Director of an approved State under paragraph (d) of this section, or

(2) With a composite liner, as defined in paragraph (b) of this section and a leachate collection system that is designed and constructed to maintain less than a 30-cm depth of leachate over the liner.

(b) For the purposes of this section, composite liner *means a system consisting of two components; the upper composite must consist of a minimum 30-mil flexible membrane liner (FML), and the lower component must consist of at least a two-foot layer of compacted soil with a hydraulic conductivity of no more than $1x10^{-7}$ cm/sec. FML components consisting of high density polyethylene (HDPE) shall be at least 60-mil thick. The FML component must be installed in direct and uniform contact with the compacted soil component.*

(c) When approving a design that complies with paragraph (a)(1) of this section, the Director of an approved State shall consider at least the following factors: 1025

(1) The hydrogeologic characteristics of the facility and surrounding land;

(2) The climatic factors of the area; and

(3) The volume and physical and chemical characteristics of the leachate.

(d) The relevant point of compliance specified by the Director of an approved State shall be no more than 150 meters from the waste management unit boundary and shall be located on land owned by the owner of the MSWLF unit. In determining the relevant point of compliance State Director shall consider at least the following factors:

(1) The hydrogeologic characteristics of the facility and surrounding land;

(2) The volume and physical and chemical characteristics of the leachate;

(3) The quantity, quality, and direction, of flow of ground water;

(4) The proximity and withdrawal rate of the ground-water users;

(5) The availability of alternative drinking water supplies;

(6) The existing quality of the ground water, including other sources of contamination and their cumulative impacts on the ground water, and whether the ground water is currently used or reasonably expected to be used for drinking water;

(7) Public health, safety, and welfare effects;..."

Did the staff perform the site-specific evaluations specified in the above quoted section from Subtitle D regulations as part of developing the permit for the proposed landfill?

If not, why not?

If this evaluation was conducted, what was the conclusion with respect to each of the listed items that led the staff to believe that a single composite liner of the type that the staff proposed for the landfill would prevent any of the constituents listed in Table 1 from exceeding the drinking water MCLs at the point of compliance for groundwater monitoring for as long as the wastes represent a threat? 1026

In developing the permit for the landfill, did the staff assume, without conducting the evaluation required in Subtitle D, that a minimum Subtitle D liner system, landfill cover and the proposed groundwater monitoring system would comply with the Subtitle D groundwater protection requirements of preventing pollution by Subtitle D Table 1 constituents that exceed a drinking water MCL at the point of compliance for groundwater monitoring for as long as the wastes represent a threat? 1027

Have the staff properly developed the permit for the landfill based on Subtitle D requirements for site-specific evaluations? 1028

Lysimeters

Is the purpose of the vacuum cup lysimeters that are installed under each of the landfill waste management unit cells that of providing early warning of leakage through the liner? 1029

How many lysimeters will be placed under each landfill cell? What is the total area of each landfill cell? 1030 1031

What is the zone of capture of each lysimeter, i.e. how far does a lysimeter sample into the vadose zone underlying a waste management unit? 1032

Is it possible that leaks through the liner system which will develop would not be sampled by the lysimeters that the staff have proposed in the permit for the landfill? 1033

Will the lysimeters that have been proposed provide a reliable, effective warning system for leakage through the liner? 1034

Comments by Staff

One of the two areas that the staff chose to comment on with respect to the extensive comments that were provided to them on the deficiencies in the proposed landfill was,

"1. *The ultimate failure of minimum Subtitle D liner systems will allow leachate to enter groundwater. New landfill units should be constructed with a double composite liner. Staff agree that a double composite liner will provide greater protection of groundwater than the single composite liner specified in the tentative permit. Staff have not observed that single composite liners beneath Subtitle D landfills have failed to contain wastes. There is ample* 1035

evidence that unlined landfills leak wastes to groundwater. However, the single composite liner standard, which was implemented through RCRA Subtitle D has resulted in the construction of a significant number of single composite-lined landfills. Although the time period for observing of these single composite-lined landfills is short, they are functioning well."

What is the basis for stating that the Subtitle D landfill liner systems that have been installed since 1993 are "**functioning well**"?

How does the staff know that the minimum Subtitle D liner systems that have been installed are functioning well? 1036

What conditions would have to exist to be able to determine that the Subtitle D liner systems that have been installed since 1993 are not functioning well? 1037

Did the staff review the report that was submitted in the packet of materials as back-up to the comments on the deficiencies in the proposed permit for the proposed landfill entitled, "Detection of the Failure of Landfill Liner Systems," dated April 1996 developed by Drs. Lee and Jones-Lee? 1038

Does the staff agree with the assessment presented in that report that there is little possibility that minimum Subtitle D landfills would, at this time, be demonstrating the inevitable failure of the liner system to prevent leachate from passing through them for as long as the wastes in the landfill will be a threat? 1039

Did the staff, in their comment above, provide the Board with a reliable assessment of what is known and to be expected with respect to the performance of minimum Subtitle D landfill liner systems to prevent leachate from passing through them for as long as the wastes in the landfill represent a threat that can cause groundwater pollution, as required in Subtitle D? 1040

Is the staff aware that New York, New Jersey, Pennsylvania, Michigan, Florida, Arizona, Oregon, Kentucky, Arkansas and possibly other states will not allow a minimum Subtitle D lined landfill to be constructed over vulnerable groundwaters such as those that exist under the proposed landfill site within their state? 1041

Is the staff aware that these states require at least a double composite-lined system for municipal solid waste landfills located over vulnerable groundwater? 1042

Is the staff aware that several of these states, particularly Michigan, have addressed the problems of trying to monitor landfill liner leakage that can lead to groundwater pollution by landfill leachate by requiring that a double composite liner be used where the lower composite liner is a leak detection system for the upper liner? 1043

Is the Michigan Rule 641 approach which sets forth the requirement of a double composite liner as a more reliable approach for detecting leakage through liners than the approach that the staff have adopted for the proposed landfill? 1044

Is it appropriate to assume that the hydraulic gradient underlying a landfill will be the hydraulic gradient that exists in perpetuity, i.e. for as long as the wastes in the landfill will be a threat? 1045

Is it possible that the adjacent property owner could install a production well for either domestic or agricultural water supply that would change the hydraulic gradient and, therefore, the rate of groundwater movement underlying the proposed landfill? 1046

Could a change in the hydraulic gradient lead to a greater probability that leachate generated through leakage through the minimum Subtitle D liner system would pass the point of compliance without being detected by the monitoring wells spaced hundreds of feet apart that have zones of capture of only one foot? 1047

What provisions exist that prevent adjacent property owners from utilizing the groundwaters under their property for domestic or other water supply purposes and thereby changing the hydraulic gradient and therefore the rate at which off-site pollution of groundwaters occurs that is not detected by the monitoring well system proposed by the staff? 1048

The second comment selected by the staff covering the many issues that were raised on the significant technical deficiencies in the proposed permit for the landfill was:

"2. *The minimum Subtitle D, Chapter 15 approach to closure is insufficient. A single composite barrier is required in the cover system for areas overlying compositely lined areas (module 13 and subsequent modules). This single composite barrier exceeds the minimum requirements of Subtitle D. The minimum RCRA Subtitle D requirement does not require a 1 x 10^{-5} cm/sec clay barrier layer. A four foot thick cover is required over unlined modules. This cover consists of two feet of foundation material, one foot of clay and a foot of topsoil to support vegetation. As long as the clay layer is properly maintained and repaired during the closure/post-closure period, this cover will provide protection of landfilled wastes from infiltration of significant amounts of precipitation. The landfill owner must protect the clay barrier layer from erosion, desiccation and differential settlement which can affect the integrity of the clay barrier layer in the cover.*" 1049

Did the staff review the report developed by Dr. G. Fred Lee and Dr. Jones-Lee that was submitted to the staff entitled, "Overview of Landfill Post-Closure Issues," as well as several other papers and reports included in the submitted materials which discussed the inability of a minimum Subtitle D landfill cover of the type proposed by the staff for the landfill to prevent leachate generation that will ultimately lead to groundwater pollution?

Is the desiccation cracking of clay layers in landfill covers well known in the literature? 1050

Did the staff review the materials that were submitted on the state of Wisconsin's experience with an experimental landfill cover at the Omega Hills site which was published in a US EPA report in 1990 covering landfill covers, where in a three-year period one-half inch wide desiccation cracks occurred to a depth of over three feet in the landfill cover? 1051

Does the staff contend that visual inspection of the surface topsoil layer of a landfill that the landfill operator will be able to maintain the integrity of the cover for the closed waste management units so that the designed permeability of the cover will be maintained in perpetuity, i.e. as long as the wastes represent a threat? 1052

If so, how will the landfill operator be able to learn of the desiccation cracks that will occur within the first season after the landfill cover is installed since these cracks will only occur in the low permeability layer which lies below the topsoil layer and the drainage layer? 1053

Is the statement in the permit that the landfill owner must maintain the low permeability character of the cover a superficial requirement that cannot be achieved with the approaches that are normally used for cover inspection? 1054

In the materials that were submitted to the staff was information that several companies have developed leak detection systems for landfill covers. It was suggested a leak detectible cover should be required in closing filled waste management units to prevent moisture from entering the landfill and thereby generating leachate that will lead to groundwater pollution. 1055

Does the staff feel that it is appropriate to require that this readily available technology be specified in permits for all landfill closures that take place in the state? 1056

Is it a fact that the landfill covers specified in the proposed landfill permit will not achieve Subtitle D's overall groundwater protection performance standards of preventing moisture from entering the wastes that leads to leachate generation and the impairment of groundwaters by landfill-derived constituents for as long as the wastes in the landfill will be a threat? 1057

If not, why not?

Landfill Liner Organic Solvent Permeation

Is the staff familiar with the permeation of organic chemicals through HDPE liners? 1058

What is the permeation process? 1059

Can solvents, such as those used for paint removal that can be purchased at any hardware store and that can be legally disposed of in an MSW landfill waste stream by homeowners can, when the container rusts out, pass through the wastes down to the liner and through the intact liner causing groundwater pollution? 1060

Does the staff know how much groundwater pollution above drinking water MCLs for carcinogens can occur by a half gallon of the solvents that can be purchased by homeowners and disposed of in their household waste? 1061

Would the staff be surprised to learn that this could be millions of gallons of groundwater. 1062

Is the staff aware that many of these solvents are suspected human carcinogens and are regulated as carcinogens by the US EPA? 1063

A discussion was provided, in the materials that were submitted, to reference to the work of Sakti and others at the University of Wisconsin, Madison on solvent permeation of HDPE liners where it was indicated that they found that a three-inch thick HDPE liner would only retard solvents passing through the liner, which does not contain any holes, for a period of 25 years. 1064

Does the staff have any information that would show that Sakti *et al.* as well as others' assessment of the solvent permeation situation is incorrect? 1065

What consideration was given to the permeation of organic solvents through the HDPE liner in developing permits for the proposed landfill? 1066

If none, why not?

Does Subtitle D require that the staff consider whether the proposed landfill containment system will prevent groundwater pollution by the waste constituents for as long as the wastes in the landfill will be a threat? 1067

If not, why not?

Have the staff, in developing the proposed landfill permits, properly implemented Subtitle D requirements of determining whether the proposed landfill liner cover systems will protect groundwaters from pollution by waste-derived constituents for as long as the wastes are a threat? 1068

Appropriateness of Development of Permits for MSW Landfills

Is it true that since Subtitle D was promulgated in 1991 that the staff have assumed that the minimum prescriptive design landfill liner and cover standards set forth in Subtitle D of a single composite liner would meet Subtitle D's overall groundwater protection performance standard of preventing impairment of use of groundwaters by waste-derived constituents for as long as the wastes in the landfill represent a threat? 1069

Where does it state in Subtitle D that the groundwater protection performance standard can be assumed to be achieved by constructing the minimum Subtitle D liner system at all sites where landfills could be located? 1070

Must the staff make a site-specific evaluation of each proposed landfill or landfill expansion to ensure that no impairment of the beneficial uses of surface water or groundwater beneath or adjacent to the landfill occurs throughout this post-closure period for as long as the wastes in the landfill represent a threat? 1071

Breakthrough Times for Clay Liners

Exhibit 7 is a nomograph based on a Darcy's Law calculation developed by Workman and Keeble that was discussed in the materials submitted to the staff on the technical deficiencies of the proposed permit for the landfill which shows breakthrough times for various permeabilities of clay liner systems. 1072

What is the thickness of the clay in the composite liner that is recommended for the proposed landfill? 1073

Is this clay liner specified to be two feet thick with a permeability of less than 1×10^{-7} cm/sec? 1074

Based on the nomograph presented in Exhibit 7, how long would it take leachate, once it has penetrated the plastic sheeting layer, to pass through the compacted clay layer underlying the plastic sheeting layer in the composite liner? 1075

Does this nomograph show that leachate penetration of this clay layer through holes that develop in the plastic sheeting layer could occur within about seven years? 1076

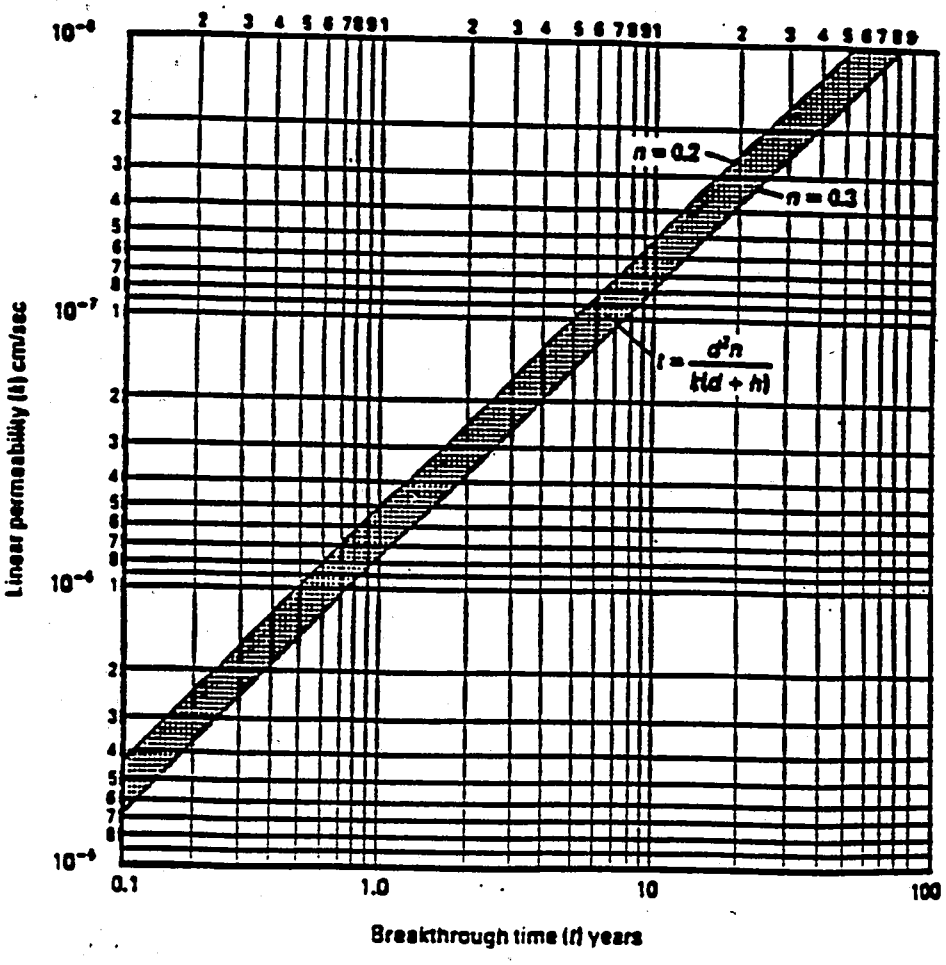
Desiccation Cracking of the Clay Layer of a Composite Liner

Is the staff familiar with the approach that is used to develop a clay liner with respect to compaction of the liner with a moisture content slightly wet of the optimum of the moisture density relationship? 1077

Does the compaction of a clay liner require the addition of moisture to the clay in order to achieve optimum compaction? 1078

Is the staff familiar with the desiccation cracking of clay layers underlying flexible membrane liners in a composite liner? 1079

Does the moisture that is used to enable optimum liner compaction leave this clay layer ,through unsaturated transport, and does the drying of this layer lead to desiccation cracks in the layer? 1080



Will the desiccation cracks that occur in the clay layer underlying the flexible membrane liner provide pathways through the clay where leaks that develop in the flexible membrane liner can penetrate the clay layer in less than the predicted rate of about seven years? 1081

Exhibit 7

Calculated Breakthrough Time for a 1-m Thick Clay Liner and 0.3-m Water Head

(Workman and Keeble, 1989)

IN: *Sanitary Landfilling: Process, Technology and Environmental Impact*, Academic Press

Did the staff review this issue in the materials that were provided to them on the proposed deficiencies of the single composite liner recommended by the staff as being suitable for the proposed landfill? 1082

What provisions were taken by the staff in developing their recommended permit for the proposed landfill which includes a single composite liner, to address the desiccation cracking of the clay layer underlying the flexible membrane liner in the composite liner? 1083

Leachate Component Attenuation

Statements are made by landfill applicants, their consultants and regulatory agency staff who want to gain approval for a particular landfill that the clay layer in a composite liner and the natural geological strata represents additional barriers due to attenuation of constituents in the clay and the underlying geological strata. 1084

Is the staff familiar with the attenuation processes that occur for municipal landfill leachate components in clay layers? 1085

Is it appropriate to assume that all municipal solid waste MSW landfill leachate components that are a threat to groundwater pollution will be attenuated, i.e. prevented from transport, in passing through the underlying clay layer in a composite liner and through the natural geological strata at the landfill site? 1086

Are there components in municipal solid waste leachate that are not attenuated to any significant extent by clays or natural geological strata and thereby move at about the same rate as water, eventually leading to groundwater pollution by the waste-derived constituents? 1087

Should the staff become familiar with attenuation issues for municipal landfill leachate before they advise the Board that attenuation is an important mechanism for preventing leachate-derived constituents from polluting groundwaters under the proposed landfill? 1088

Did the staff mislead the Board in its attempt to support the permit for the proposed landfill when it stated that the leachate components that pass through the plastic sheeting liner would be attenuated and therefore would not be a threat to pollute groundwaters? 1089

Final Questions

Will the recommended permit for the proposed landfill comply with Subtitle D requirements of protecting groundwaters from impaired use for as long as the wastes in the landfill will be a threat? 1090

Does the current regulatory approach, in which it is assumed by the staff that a minimum Subtitle D landfill liner system consisting of a thin plastic sheeting layer and two feet of clay or equivalent, provide for groundwater quality protection for as long as the wastes are a threat? 1091

Is it appropriate to assume that a minimum Subtitle D composite liner will comply with Subtitle D's performance standards of protecting groundwaters from impaired use for as long as wastes represent a threat at a site where it already has been demonstrated that groundwaters are vulnerable to pollution by landfill leachate based on the pollution of groundwaters by existing waste management units located in that area? 1092

Is it appropriate to conclude that the proposed permit conditions for the landfill will protect groundwaters in the vicinity of the landfill from being polluted by landfill leachate for as long as the wastes in the landfill will be a threat? 1093

If not, why not?

Is it appropriate to conclude that the groundwater monitoring approach proposed in the permit has a low probability of detecting leachate-polluted groundwaters at the point of compliance before pollution beyond this point occurs? 1094

If not, what is the expected reliability of these monitoring systems to detect leachate polluted groundwaters when it first reaches the point of compliance? 1095

Professional Ethics Issues

Exhibit 8 is a cover page for a paper that discusses the significant professional ethics problem that exists today in landfill permitting where landfill applicant consultants and in some cases regulatory agency staff do not tell the board and public the whole truth about the ability of a landfill liner system and groundwater monitoring system for a particular landfill to protect groundwaters from impaired use for as long as the wastes in the landfill will be a threat. 1096

Do you agree that there is a significant professional ethics problem in the landfill development field today with respect to the permitting of municipal solid waste landfills?

Does the staff understand that if a consultant who normally works on behalf of landfill applicants discusses the whole truth about the inevitable failure of the landfill liner and cover systems and the inability of the groundwater monitoring system to detect this failure in leachate-polluted groundwaters they will not obtain future work from landfill applicants? 1097

Does the staff know that the American Society of Civil Engineers and the National Society for Professional Engineers have codes of ethics that require, with respect to matters of public health and safety, a civil engineer and a professional engineer to provide the public with the whole truth concerning the ability of a particular project, such as a landfill, to protect public health, groundwater resources and the environment from adverse impacts for as long as the wastes in the landfill will be a threat? 1098

FORUM

Exhibit 8

ENVIRONMENTAL ETHICS: THE WHOLE TRUTH

Do engineers working on issues concerning the impacts of chemical constituents on public health or the environment have a professional obligation to tell the whole truth? The obvious answer is yes. Unfortunately, this is often not being done today.

The field of environmental quality management has become immersed in the adversarial (legal) system for "resolving disputes" among parties with different interests—a system significantly different from the traditional engineer/scientist (E/S) approach to addressing complex environmental issues. In the adversarial system, one side presents the strongest possible technical discussion on behalf of the client; it is left to the other side to bring out the weaknesses in the technical position. While such an approach is considered appropriate in the courtroom, the problem is that it is routinely followed by E/Ss in proceedings such as appearances before regulatory boards supporting or opposing proposed projects. Engineering and other technical reports commonly do not present a disinterested discussion of technical issues and information pertinent to the protection of public health and the environment.

When the responsible, competent E/S—who is charged to tell the truth complete with caveats, qualifiers, uncertainties and unanswered questions—presents the "whole" story to the client/employer, he or she is then frequently faced with a situation in which the client or employer wants only positive project-supportive information revealed and detracting information omitted. To be useful to the client/employer, the "expert" E/S must testify or otherwise make authoritative presentation of those selected facts and information in technical reports at hearings or other review-board proceedings.

Some professionals justify doing this on the grounds that they have to "play the game." The realities of maintaining a client, securing future work, and holding and advancing one's position in a firm, along with inadequate funding to conduct quality and necessary work compel some E/Ss to exaggerate, diminish or otherwise manipulate the whole truth—despite the fact that the codes of ethics of both ASCE and the National Society of Professional Engineers emphasize the importance of full disclosure on matters of public health and safety.

One way to help neutralize the effects of the adversarial system may be to incorporate a requirement with project applications for funding independent, disinterested technical review to be presented to the regulatory agency, decision makers and public. This approach is being followed in the siting of three large landfills to serve the Greater Toronto area.

It would provide considerable impetus for project consultants and advocates to be more forthcoming with reliable information on potentially adverse project impacts if they were faced with exposure of the technical unreliability (failure to tell the whole truth) of their positions in a full peer-review public arena. Such a review could also help address "not-in-my-backyard" concerns if individuals, communities and interest groups had a mechanism for independent review and reporting of technical information they felt they could trust. To fund this peer-review process, a percentage of the cost of any proposed project with potentially significant public-health or environmental-quality implications could be made available.

While environmental impact statements (or, in California, environmental impact reports) should by law provide the vehicle for full technical disclosure of potential problems associated with the project, such documents rarely provide reliable in-depth review of complex technical issues, especially as they relate to chemical constituents in the environment. Every project applicant should be required to conduct plausible worst-case-scenario evaluations for projects involving management of chemical constituents in the environment.

Such evaluations must include consideration of the nature, transport, fate and effects of chemical constituents under plausible worst-case conditions; the ability of the project's monitoring system to detect impending public-health and environmental-quality impairment under plausible worst-case conditions; the actions that would be taken in response to such detection; the magnitude of harm to public health and environmental quality that could result from inadequate response actions to plausible worst-case conditions; the magnitude and source of funding available for corrective action required under plausible worst-case conditions for as long as the wastes and/or chemicals represent a threat; and the adequacy of the public-health and environmental-protection regulatory standards or other requirements applicable to the project, as well as potential future changes in those standards. The plausible worst-case-scenario evaluation would be provided for peer review of the project.

Adoption of this approach would provide the public, the regulatory community and officers of the courts with a much better understanding of the potential consequences of undertaking a particular project or activity. It would also be a major step in reversing the tide of unethical practices that have become common among engineers and scientists in the environmental quality-management field today.

[This Forum is condensed from a more comprehensive review of the topic, available from the authors at tel. 916/753-9630; fax 916/753-9956.]

G. Fred Lee, P.E.
Anne Jones-Lee
G. Fred Lee & Associates
El Macero, Cal.

Do you agree that Drs. Lee and Jones-Lee's suggested approach as discussed in this paper (Exhibit 8) of requiring a full, public, independent peer review of controversial technical issues concerning a proposed landfill is an appropriate approach to follow to better ensure that future generations' groundwaters will not be polluted by landfill leachate than is being followed today in the permitting of landfills? 1099

Does the staff feel that the independent peer review approach is an appropriate approach to take with respect to protecting public health, the environment and the public's interests? 1100

Do you agree that regulatory agency staff typically understand the significant problems that exist today of permitting landfills that will not protect groundwaters from pollution by landfill leachate for as long as the wastes represent a threat? 1101

Does this problem exist in your regulatory agency? 1102

Who in the agency is responsible for continuing the policy of having the staff recommend permits for landfill liners and covers and groundwater monitoring systems that, based on what is well-established in the professional literature, obviously will not be protective of groundwater resources associated with the landfill for as long as the wastes represent a threat? 1103

What needs to be done to change the current landfill permitting situation so that true groundwater quality protection can be achieved in the landfilling of municipal solid wastes at the proposed landfill? 1104

Based on our discussions of issues, is it appropriate to require that the people who deposit wastes in the landfill pay the true cost of protecting groundwaters from impaired use for as long as the wastes in the landfill will be a threat? 1105

Will the permit that is recommended by the staff for the proposed landfill provide protection of groundwater resources from impaired use for as long as the wastes represent a threat? 1106

The questions appearing at page 2 through 28 have been submitted at the suggestion of Dr. G. Fred Lee. Engineering experts such as Dr. Lee continue to conclude that landfill liners constitute a "flawed technological approach." Exh. 9 (copy of one of the articles cited in Exh. 1). (Exhibits 9 through 101 appear following page 45 of these comments and are incorporated herein by reference as though set forth in full in the text of these comments.) The EIR is deficient because it fails either to disclose the more recent literature on the issue, or to discuss its significance. Does the Planning Department agree with the conclusions expressed in the articles cited in Exhibit 1? If not, why not? 1107 1108

It has been reported that waste constituents are likely leaving landfills in the vapor phase in addition to or in place of the liquid phase. See Exh. 12 (Air/Water Pollution Report 1996). The EIR is deficient because it does not reveal this additional source of contamination. Was the Planning Department aware at the time of the release of the EIR of the information contained in the Air/Water Pollution Report article? If not, why not? Does the Planning Department agree that BFI should be required to reveal whether vapor phase is a source of landfill contamination at Sunshine Canyon? If not, why not? 1109 1110 1111

Page B5-13 of the EIR indicates that portions of the landfill will be built over the top of existing landfill. The EIR fails to disclose that as recently as 1994, according to the industry publication World Waste:

> there are still concerns about building a new landfill on top of existing solid waste. Since the MSW settles at it biodegrades and shifts under the weight of the new waste, the former landfill's instability can threaten the integrity of the new liner system. 1112
>
> * * *
>
> A piggyback landfill is not recommended for existing sites with leachate and groundwater contamination problems since it would be difficult to determine whether the source of the problem was the old or the new landfill.
>
> Even as engineers develop technology to support piggyback landfills, regulators remain cautious about approving piggyback landfills due to long term performance uncertainties.

Exh. 11. The same article also indicates that existing compaction techniques to control differential settlement are effective only to a level of about 40 feet. Was the Planning Department aware at the time the EIR was released of these concerns about the "long term performance uncertainties of a piggyback or waste-on-waste landfill, such as that resulting from the shifting of old waste under new waste? If not, why not? Was the Planning Department aware at the time the EIR was released of these concerns about the limited effectiveness of existing compaction techniques? If not, why not? The failure to disclose this information is an EIR deficiency. The City should require the applicant to disclose all relevant geological and engineering studies regarding these long term performance uncertainties. 1113 1114 1115

The U.S. Geological Survey has prepared a report (No. 95-213) which states that the mountain range in which the landfill is located is particularly vulnerable to landslides. USGS 1995 (excerpt). The EIR indicates at page 4-39 that a 1995 report prepared by the U.S. Geological Survey was consulted, but the full citation is not provided, so it is not possible based on the information provided to verify its accuracy. Other scientists predict that there will be future earthquakes in the area of the landfill that will be even larger (7.2 - 7.6) than the Northridge earthquake of 1994. See Exh. 12. Although the EIR rerveals that it is reasonable to expect a earthquake larger than the Northridge Earthquake, it is deficient because it fails to reasonably quantify the predicted size of the larger quake. 1116 1117

In April of 1997, the California Division of Mines ("DMG") and Geology stated that in assessing seismic hazards, consultants should use the latest DMG "seismic ground-motion parameter data." See Exh. 13. The EIR is deficient because it does not state whether these data were used in preparing the Sunshine Canyon EIR. Does the Planning Department agree that BFI should be required to use these data? If not, why not? Page 13 of the Static and Seismic Stabilty Assessment (11/96) states that "the Northridge Blind-Thrust event can be eliminated from further consideration" in part because its PGA of .71 g is less than the .81 g of the Santa Susana MCE. In fact, the Northridge Earthquake produced "maximum peak accelerations reaching 1 g" at the Van Norman Complex (see Exh. 14 (Bulletin of the Seismological Society of America (Bardet and Davis) 1996), and "peak acceleration near 1 g" at the Interstate 5/14 interchange (see Exh. 15 (Bulletin of the Seismological Society of America (Hutchings & Jarpe) 1996). The EIR is deficient because it does not reveal this information or discuss its significance. Was the Planning Department aware of the magnitude of the accelerations 1118 1119 1120 1121

produced by the Northridge Earthquake at these two sites, both of which are in close proximity to Sunshine Canyon? If not, why not? The EIR is deficient because it excludes from consideration relevant information about the acceleration produced by the Northridge Earthquake. We request that BFI be required to circulate a new EIR which explains why this information was not made available to the public. 1122

Page C8-8 states that aftershock activity from the Northridge Earthquake "has been concentrated to the north and northwest of the epicenter." In fact, one of the greatest concentrations of aftershocks appears to be in an area which includes Sunshine Canyon. See, for example, Exh. 14 at page S336 (Bulletin of the Seismological Society of America (Bardet & Davis) 1996). The EIR is deficient because it does not reveal this information or discuss its significance. Was the Planning Department aware of where the aftershocks were concentrated at the time the EIR was released? If not, why not? Does the Planning Department agree, after independently reviewing the evidence, that the EIR is at best inaccurate in stating that the aftershocks have been concentrated to the northwest of the epicenter? If not, why not? BFI should be required to circulate a new EIR which explains the engineering significance of the concentration of the large number of Northridge Earthquake aftershocks in an area which includes Sunshine Canyon. 1123 1124 1125 1126

During the hearings before the County Board of Supervisors regarding the expansion of this landfill, BFI attempted to downplay the numerous examples of its corporate misconduct and claimed that it had been, was, and would be a responsible corporate citizen. See Exh. 16. BFI's claim was false. In fact, numerous recent incidents have been reported which indicate that BFI's misconduct is continuing. For example, 1127

- in 1996 BFI Services was accused of violating the Clean Water Act ("CWA") based on the improper disposal of millions of gallons of mixed raw sewage. "In many instances, [BFI services] gave the [publicly owned treatment works] false samples of waste slated for disposal . . . ." Exh. 17. This misconduct defrauded municipal sewage plants of about $1.3 million." Exh. 18. As part of a guilty plea arising out of this misconduct, BFI Services paid a $3 million fine and $1.5 million in restitution for violating the CWA. See Exh. 19. 3.

- In 1995, BFI shut down and dismantled a medical waste incinerator after admitting to tampering with monitoring devices. See Exh. 20 1128
- In 1997, BFI was accused of illegally operating a construction and demolition debris transfer station in Florida. See Exh. 21. 1129
- In 1997, federal authorities raided a BFI medical waste disposal plant in Washington DC as part of an investigation into illegal dumping of biomedical waste. See Exh. 22. 1130
- In 1990, BFI abandoned plans to expand one of its landfills after admitting that it had suppressed reports showing potentially explosive methane gas in the landfill and garbage buried beyond the permitted area. Previously, BFI had boasted of "sound management practices and environmental protection." See Exhs. 23 & 24. 1131
- In 1990, Louisiana officials determined that BFI "continued to break the law" through landfill operating violations such as failing to apply proper cover material, illegally disposing of infectious medical waste, failing to keep litter from blowing off the site, and allowing contaminated liquid to seep from the landfill. The officials found that "the facility has a history of serious violations which are corrected but then reoccur . . . ." BFI eventually closed the landfill. See Exhs. 25-27. 1132
- Recent legal or administrative actions against BFI landfills have been filed based on issues such as garbage odor, dust and blowing debris, improper receipt of hazardous waste, liner failure, surface and ground water contamination, and adverse health impacts at landfills near San Antonio, Texas (see Exhs. 28 (garbage and sludge odors, dust and blowing debris, reported in 1996) & 29 (odors and mud spread by garbage trucks, reported in 1997)), Houston, Texas (see Exhs. 30 (air and water pollution, reported in 1995); Donna, Texas (see Exh. 31 (admitted violations by BFI at several landfills, reported in 1992)); Baltimore, Maryland (see Exh. 32 (ground water pollution, reported in 1994)); Reading, Pennsylvania (see Exh. 33 (citation for unpermitted discharge of leachate from lined 1133

landfill, reported in 1994)); Cleveland, Ohio (see Exhs. 34 (odor, reported in 1992) & 35 (noise and odor, reported in 1997)); San Mateo, California (see Exh. 36 (streambed destruction resulting from storm water overflow during landfill expansion, reported in 1993)); Pittsburg, California (see Exh. 37 (odors and blowing dust and trash, reported in 1993)); and in Ohio, Alabama and New York (see Exh. 38 (alleged illegal burying of sludge, reported in 1991)), Louisiana (see Exhs. 39 (1,400 violations of hazardous waste regulations, reported in 1990) & 40 (odors and noise, reported in 1989 and 1993)); Illinois (see Exh. 41 (depositing waste in excess of permit limit, reported in 1997)); and Virginia (see Exh. 42 (odors, reported in 1997)).

- In 1996, the federal government sued BFI for attempting to monopolize waste hauling competition in states such as Tennessee. BFI settled the lawsuit by agreeing to make changes in its contracting practices. See Exh. 43. 1134
- Additional examples of BFI's record of fines, suits and penalties prior to 1992 are set forth in the article enclosed as Exh. 44. 1135

Were the Planning and/or Zoning Departments aware of these allegations and incidents at the time of the release of the EIR? If not, why not? 1136 Do the Planning and/or Zoning Departments agree that by diverting material away from landfills, it would reduce or eliminate the need for the City of Los Angeles to entrust the important function of waste disposal to an entity such as BFI with such a questionable record and reputation? If not, why not? 1137 Do the Planning and/or Zoning Departments planning staff agree that as a general rule the recycling industry has a better operating record in terms of environmental health and safety than the landfilling industry? If not, why not? 1138 Do the Planning and/or Zoning Departments agree that BFI's operating record is a relevant factor in determining its suitability to conduct an important public function such as waste disposal? If not, why not? 1139

Section 4.11 of the EIR states that the expansion of the landfill will not have an adverse effect on property values. The attached article however, states that "it is reasonable to assume that unless new landfills achieve a state of operations such that the urban housing markets view them as essentially benign, one 1140

should expect that landfills will have negative price effects." See Exh. 45. The EIR also states, however, that the operator will be unable to mitigate the adverse air quality impact of operating the landfill. The EIR is defective because it fails to disclose studies which demonstrate the adverse impact of landfills on residential property values. Was the Planning Department aware of the facts and conclusions set forth in Exhibit 45 at the time the EIR was released? If not, why not? Does the Planning Department agree with the analysis and conclusions set forth in Exhibit 45? If not, why not? "It has become a common practice among major landfill operators to provide property value guarantee programs as part of the process of seeking government approval for expansion or construction of landfills." Exh. 46 (Appraisal Journal 1996 (see "Question 9")). BFI is reported to have extended or offered to extend property value guarantees with respect to several of its sites. See, for example, Exhs. 47 (Chicago Tribune 1993), 48 (Chicago Tribune 1995); 48.5 (Buffalo News 1992); 49 (Air Water Pollution Report 1995); 50 (News & Observer 1992). Property value guarantee programs offered by other landfill operators are described in Exhibits 52 (Pantagraph 1997); 53 (Chicago Tribune 1996); 54 (Post Standard 1996), 55 (Indianapolis Star 1996); 56 (Kansas City Star 1995); 57 (Leader Telegram 1993); and 58 (Tacoma News Tribune 1995). Were the Planning and/or Zoning Departments aware that it has become a common practice among major landfill operators to provide property value guarantee programs as part of the process of seeking government approval for expansion or construction of landfills? If not, why not? Do the Planning and/or Zoning Departments agree that BFI should be required to offer a property value guarantee program as a condition of obtaining a zoning change and/or a permit to operate the landfill? If not, why not? Do the Planning and/or Zoning Departments agree that if the proposed landfill will have no adverse effect on property values--as BFI claims in section 4.11--BFI will have nothing to lose by offering a guarantee program? If not, why not?

1141
1142
1143
1144
1145
1146
1147

The EIR claims that the landfill is needed to solve an "impending crisis" in landfill capacity. EIR p. I-8. In fact, the crisis does not exist, as stated in Exh. 59 (Los Angeles Times 1993) and 60 (Wall Street Journal 1996). In April of 1997--prior to the release of this EIR--the City of Los Angeles Bureau of Sanitation issued a Request for Qualifications regarding the development of "Innovative Solid Resources Management Technologies." The EIR is deficient because it does not refer to this document in the alternatives section, describe the current status of the proposal process, or provide any estimates of the

1148
1149

extent to which these technologies will reduce the need for expansion of the landfill. Was the Planning Department aware of the Request for Qualifications, or of any subsequent procedures or developments within the Department of Public Works relating to the use by the City of Los Angeles of innovative solid resources management technologies? If not, why not? It has also been recently reported that "[m]any curbside recycling programs could face extinction by state and local governments anxious to fill space at cheap 'mega-landfills.'" See Exh. 61 (Solid Waste Report 1997). The EIR is deficient because it does not describe the extent to which the expansion of this landfill, with its artificially low tipping fees, will jeopardize the recycling programs implemented by the City of Los Angeles. Was the Planning Department aware at the time the EIR was released of the study referenced in Exhibit 61? If not, why not? Does the Planning Department agree with the conclusions reached in the study referenced in Exhibit 61? If not, why not? A report entitled "Approaching an Integrated Solid Waste Management System for Los Angeles County, California" (Gershman, Grickner & Bratton Sept. 13, 1996)("GBB Report") concluded that "Los Angeles County can effectively meet and exceed its AB 939 requirements without opening new landfills" by "diverting solid waste away from landfills through source reduction, recycling, and composting." See Exh. 62. The EIR is deficient because it does not disclose the existence of this report in its discussion of project alternatives. Was the Planning Department aware of the GBB report at the time that the EIR was released? If not, why not? Does the Planning Department agree with the conclusions set forth in the GBB report? If not, why not? The alternatives section of the EIR is also defective because it does not discuss the extent to which landfill capacity could be preserved by the diversion of inert wastes. Specifically, public works officials in other jurisdictions are recently reported to have predicted a diversion rate of 20 percent by disposing of inert wastes in separate landfills. See, for example, Exh. 63. Page V-18 of the GBB Report demonstrates that there is ample inert waste capacity within Los Angeles County. Was the Planning Department aware at the time the EIR was released about the potential for preserving MSW landfill capacity by mandating the diversion of inert waste? If not, why not? Does Planning and/or Zoning Staff agree that MSW landfill capacity could be preserved by mandating the diversion of construction waste? If not, why not?

Under the California Environmental Quality Act ("CEQA"), the EIR must consider both primary and secondary consequences in determining whether the project may have a significant impact on the environment. Primary and direct consequences are those

1160

immediately related to the project, such as dust resulting from project construction or operations. Secondary or indirect consequences may be "several steps removed from the project in the chain of cause and effect." See CEQA Guidelines § 15064. The United States Environmental Protection Agency ("EPA") has determined that air pollutant emissions from Municipal Solid Waste landfills pose a risk to human health and the environment. Landfill emissions of Volatile Organic Compounds and Nitrous Oxide exacerbate violations of the ambient standard for ozone; the formation of ozone in the breathable atmosphere has a broad spectrum of adverse health consequences and also causes harm to plant life. Emissions of methane contribute to global warming under the greenhouse theory. Emissions of substances such as vinyl chloride and benzene pose a risk of cancer and other disease. Unlike most sources of industrial air emissions which are periodic and which can be controlled or eliminated, landfill emissions occur continuously and cannot be adjusted. Even when control devices are operating correctly, approximately 2 percent or more of collected gasses (including significant portions of the more hazardous non-methane organic compounds) pass through the control device without being destroyed. See, for example, Exh. 37 at p. 8. Does the Planning Department agree that adverse impacts on human health result from landfill operations constitute at least a secondary impact within the meaning of CEQA? If not, why not? The EIR is also deficient because by indicating at page 4-92 that "uncollected" landfill gas consists primarily of methane, it diverts attention from the fact that in absolute (as opposed to relative) terms, landfills nationwide are reported to emit approximately 255,000 metric tons of highly toxic nonmethane organic compounds each year. See Exh. 65 (San Francisco Chronicle 1991). The EIR is also deficient because it does not reveal the fact that technology exists to neutralize the odors that emanate from landfills. See Exh. 66. Was the Planning Department aware of the existence of this technology at the time the EIR was released? If not, why not? The particulate matter (PM-10) that landfills also generate has severe health consequences. The adverse affects of landfills on public health have been documented. Support for the statements made in this paragraph are found in publications such as: US EPA, "Air Emissions from Municipal Solid Waste Landfills--Background Information for Proposed Standards and Guidelines" p. 2-1 through 2-33 (1991)(Exh. 67 (excerpt)); David H. Minott, "Landfill Environmental Emissions--Regulatory Progress and Gaps" (1994)(Exh. 68); Donald L. Gill, "Landfill Gas Emissions: A Study of Two Landfills in Prince George's County, Maryland" (1995)(Exh. 64); Kay H. Jones, "Comparing Air Emissions From Landfills and WTE Plants," Solid Waste Technologies (March/April

1161 1162 1163 1164 1165 1166 1167 1168 1169 1170

1994) at p. 30 (Exh. 69); D.W. Dockery and C.A. Pope III, "Acute Respiratory Effects of Particulate Air Pollution," 15 Ann.Rev.Pub.Health 107 (1994)(Exh. 70). Was the Planning Department aware of the facts set forth in the articles attached as Exhibits 64 through 70? If not, why not? Does the Planning Department agree with the conclusions expressed in the articles attached as Exhibits 64 through 70? If not, why not? The EIR is deficient because it minimizes and fails to adequately analyze these secondary environmental consequences. The EIR is also deficient because it fails to provide emissions estimates for the entire life of the landfill, and fail to disclose the extent to which the landfill flares or incinerators will generate a visible plume, or contribute to haze, or have other visibility impacts. The EIR is also deficient because the analysis of dioxin emissions is inadequate, and the mitigation analysis for NOx and CO is inadequate. As a preferable alternative to flares/incineration, the landfill could use energy recovery technology, such as reciprocating engine or gas turbine with zeolite catalysts installed to reduce NOx emissions. See Exhs. 71 & 72. Was the Planning Department aware of the existence of this technology at the time the EIR was released? If not, why not? Does the Planning Department agree that the technology described in Power Magazine is superior to landfill gas flaring/incineration? If not, why not? Does the Planning and/or Zoning Departments agree that in view of the health impacts described above, (1) any mitigation should include enforcement by the City of Los Angeles of the zoning condition regarding a health study and require BFI to fund a study, to be supervised by a major university and/or an independent agency of the federal government prior to construction, to assess the health impacts of landfills that have already been sited (including closed landfills) and other undesirable land uses on the residents of the impacted area, and (2) BFI should be required to fund ongoing health surveys in the area on a periodic basis throughout the life of the landfill and the closure period. Page 4-316 of the SEIR states that an epidemiological study would not be warranted because area residents are "concern[ed]" about "health issues." If this were a valid consideration in determining whether to conduct a health study of a facility such as a landfill, because as shown above most people who live near a landfill are legitimately concerned about health issues. But in fact, health studies have been designed and conducted regarding the health effects of municipal solid waste landfills. See, for example, Exh. 73 (Archives of Environmental Health 1995); see also Exh. 74 (NIEHS Press Release 1997 (describing health study of residents living near landfill that accepted both household and hazardous waste)). Does the Planning Department agree that people who live

1171 1172 1173 1174 1175 1176 1177 1178 1179 1180 1181 1182 1183 1184

near landfills have legitimate concerns about health issues? If not, why not? Was the Planning Department aware, at the time the EIR was released, that health studies have been conducted of persons living near landfills accepting municipal solid waste? If not, why not? Does the Planning Department agree that, in view of the essential similarity of the constituents of the leachate from a municipal solid waste landfill and the leachate from a hazardous waste landfill (see Exh. 98), a health study of residents living near a municipal solid waste landfill will be as valid as a health study of persons living near a hazardous waste landfill? If not, why not? 1185 1186

The EIR also fails to consider the cumulative impact of the polluting effects of the landfill. For example, the Northeast San Fernando Valley are already burdened with a large number of undesirable land uses, including landfills. Examples of landfills and other undesirable land uses are believed to exist in the impacted area at this time, or sufficiently near to the impacted area to cause adverse health effects to the community: Bradley Landfill (East), Bradley Landfill (West), Lopez Canyon Landfill, Strathern Landfill, Valley Reclamation Landfill, CalMat Landfill, Community Recycling (aka DeGarmo St. Dump), Sheldon/Arleta Landfill (closed), Skyview Terrace Landfill (closed), Elsmere Canyon Landfill (proposed), and Chiquita Canyon Landfill. See also Exh. 75. Many of these landfills have a record of causing health problems. See "Has Landfill at Lopez Canyon Had Its Fill?", Los Angeles Times (Feb. 17, 1995) (statement of administrator of residence facility for senior citizens)(Exh. 76). Government officials are on record as stating that it was a mistake to cluster so many garbage dumps near the area to be impacted by this landfill. See "The Enemy Below L.A.", Los Angeles Daily News (statement of Regional Water Quality Control Board administrator that "with today's knowledge . . . you wouldn't have seen that many landfills in that area.")(Exh. 77). The siting of this landfill in this impacted area, near a community that is heavily populated by members of minority groups, is inconsistent with the principles of environmental justice. Were the Planning and/or Zoning Departments aware of the reported statement by the Water Quality Control Board administrator at the time the EIR was released? If not, why not? Does the Planning and/or Zoning Department agree that the Northeast San Fernando Valley has been forced the assume the burden of a disproportionate share of landfills in relation to the rest of the City of Los Angeles? If not, why not? 1187 1188 1189 1190 1191 1192

The courts are holding that the Comprehensive Environmental Response, Compensation, and Liability Act of 1980, 42 U.S.C. 1193

Section 9601 ("CERCLA"), imposes liability on local governments that arrange for the disposal of municipal solid waste in landfills. Examples of such decisions are B.F. Goodrich Co. v. Murtha, 958 F.2d 1192 (2d Cir. 1992)(Exh. 78) and Transportation Leasing Co. v. State of California, 861 F.Supp. 931 (C.D.Cal. 1993)(Exh 79). The Murtha case recognizes that even if it is assumed that municipal solid waste contains a low concentration of hazardous substances (p. 1197), a municipality may be subject to CERCLA liability if "that waste contains a hazardous substance, found in <u>any amount</u>" at a landfill (p. 1206 (emphasis added)). The Transportation Leasing case held that Los Angeles County could be subject to CERCLA liability for arranging for the disposal of residential waste in a landfill later found to contain toxic substances (p. 947-48). The existence of toxic substances in municipal landfills occurs because municipal solid waste either (1) contains hazardous waste, or (2) decomposes and transforms into hazardous waste when deposited in a landfill. See, for example, Debra R. Reinhart, "A Review Of Recent Studies On The Sources Of Hazardous Compounds Emitted From Solid Waste Landfills," 11 Waste Management & Research (July 1993) at p. 257 (Exh. 80); Steven Ferrey, The Toxic Time Bomb: Municipal Liability for the Cleanup of Hazardous Waste, 57 George Washington Law Review 197, 200-10 (1988)(Exh. 81). Dr. Kirk W. Brown, of Texas A&M University has concluded that the waste streams disposed of in municipal landfills contain hazardous wastes; his methodology has been determined to be admissible in a federal court case. See Exh. 82 (excerpt). The EIR is deficient because it does not reveal or analyze the information set forth in Exhibits 75 through 82. Was the Planning Department aware of the conclusions set forth in Exhs. 75 through 82 at the time the EIR was released? If not, why not? Does the Planning Department agree with the facts and conclusions set forth in Exhibits 75 throuogh 82? If not, why not? The courts are also holding that the adverse impacts from landfill operations are a "basis for inverse condemnation." See "Expansion of Dump is a Taking By County," California Environmental Insider (July 13, 1995) at p. 9 (Exh. 83). Was the Planning Department aware of the City's exposure to liability as a result of using municipal landfills to dispose of waste? If not, why not? Instead of exposing the City (and its citizens) to economically catastrophic landfill liability, the officials of this City should be using alternative methods for the disposal of discarded materials. The economic and environmental feasibility of these alternatives has been demonstrated. See, for example, Victor Dricks, "Community Profits From Its Waste," Phoenix Gazette (Aug. 29, 1994)(Exh. 84); Richard Gilbert, "Finances of Incineration and Landfill Facilities" (1995)(Exh. 85); Southern California Edison, "Edison 1194 1195 1196 1197 1198 1199 1200 1201

Advanced Integrated Recycling (AIR) Project Description (1993)(Exh. 86). The EIR is deficient because it does not reveal or analyze the information set forth in available materials such as those included in Exhibits 83 through 86. Was the Planning Department aware of the facts and conclusions appearing in Exhibits 83 through 86? If not, why not? Does the Planning Department agree with the facts and conclusions set forth in Exhibits 83 through 86. If not, why not? se or similar articles at the time the EIR was released? If not, why not? Does Planning and/or Zoning Staff agree with the conclusions set forth in these articles? If not, why not? 1202 1203 1204 1205

The EIR does not adequately reflect that the proposed landfill is itself a "source" which must obtain an NSR permit and that the proposed landfill gas collection and flare system merely represents the air pollution control equipment proposed by the applicant to control its landfill gas emissions. This comment is based on the relevant provisions of the Clean Air Act ("CAA") and implementing EPA regulations and guidance, which the SCAQMD is responsible for implementing in Los Angeles County pursuant to CAA § 173 and the California State Implementation Plan. Specifically, as buried waste decomposes in the landfill, landfill gas will be generated and emitted to the atmosphere. Landfill gas consists of methane, carbon dioxide and various reactive organic compounds. As such, landfill gas (and each of its constituents) is an "air pollutant" as that term is defined by CAA Section 302(g), 42 U.S.C. § 7202(g)("air pollutant" is "any air pollution agent or combination of such agents, including any physical, chemical . . . substance or matter which is emitted into or otherwise enters the ambient air"). Because it will emit air pollutants, the landfill is a "stationary source" for CAA purposes. See CAA § 302(z), 42 U.S.C. § 7602(z)("stationary source" is "generally any source of an air pollutant except those emissions resulting from an internal combustion engine for transportation purposes or from a nonroad engine or nonroad vehicle . . . "); CAA § 111(a)(3), 42 U.S.C. § 7411(a)(3)("'stationary source' means any building, structure, facility, or installation which emits or may emit air pollutant"); 56 Fed.Reg. 24468, 24475 (May 30, 1991)(the "facility" is the "entire landfill," which is "the total landfill property designated for solid waste disposal . . . ."). The discussion of the applicable air quality rules should make it clear that preconstruction review of the landfill's air emissions must occur before the landfill is constructed, rather than at the time the applicant chooses to install its proposed air pollution control equipment. An attorney who advises the waste industry is reported to have stated that under the Clean Air Act: 1206 1207 1208 1209

> In building a new landfill, managers must figure out the site's potential to emit certain pollutants. "It's not what you actually emit, ... You have to calculate your worst case scenario.

See Exh. 87. The air quality section of the EIR is deficient because it is based on actual emissions, rather than the worst case scenario required under the Clean Air Act. Does Planning and/or Zoning Staff agree that BFI should have made worst case scenario calculations? If not, why not? 1210 1211

The information provided in the EIR regarding the efficiency of the landfill gas collection system is inadequate. The relevant EPA guidance on landfill gas emissions and NSR requires that an applicant assume that its gas collection system will be "designed to maximize, to the greatest extent possible, the capture of landfill gas from the landfill. See Exhs. 88 (copy of the EPA guidance memorandum); 89 (copy of article from Waste Age discussing the implications of the EPA guidance memorandum). The current benchmark for the maximum collection efficiency for gas collection systems at new landfills is 90 to 100%. A collection efficiency of over 90% was recently proposed for the Campo Landfill in San Diego County. Exh. 90 (excerpt). Further support for a 90-100% efficiency is found in a recent BFI application submitted by BFI in Pennsylvania. See Exh. 91. Was the Planning Department aware of of the possible efficiency levels of landfill gas collection systems? If not, why not? Will the Planning Department require BFI to explain why it proposed 90-100% efficiency at its Pennsylvania facility, but will not do so at Sunshine Canyon? If not, why not? A 90 to 100 percent efficiency should be required as part of the LAER determination. Various emissions calculations and ambient air quality modeling analyses will have to be adjusted to reflect this higher collection efficiency. Because the higher collection efficiency will result in increased NOx emissions, even more offsets will be required from the Priority Reserve or elsewhere, if the landfill is to be permitted. But the EIR does not adequately address whether the SCAQMD has sufficient emission reduction credits in its Priority Reserve to offset the emissions generated by the Sunshine Canyon landfill, let alone other landfill projects currently pending in the SCAQMD which will be making claims on the priority reserve in the same time frame. Does the Planning Department agree with the conclusions set forth in this paragraph? If not, why not? 1212 1213 1214 1215 1216 1217 1218 1219 1220

The estimates for fugitive dust are well below comparable projections made for the smaller Chiquita Canyon landfill. 1221

Specifically, at 10,000 tpd, Chiquita Canyon Landfill is estimated to have onsite fugitive PM 10 emissions of 638.9 pounds per day (Final EIR, Chiquita Canyon Landfill Table 4.G-8 at p. IV-85). By contrast, operations at Sunshine Canyon--where wind conditions are more severe--are assumed to produce no more than 102.5 pounds per day (Sunshine Canyon EIR Table 4.2.8). The EIR is deficient because it does not provide a full explanation for this discrepancy. Will the Planning Department require BFI to explain the reasons for this discrepancy? If not, why not? 1222 1223 1224 1225

Because the landfill is located in a non-attainment area, the amount of carbon monoxide emissions from the landfill expansion will result in a major modification to a stationary source, requiring use of Best Available Control Technology. The EIR should therefore evaluate a carbon monoxide catalyst as a control technology. It has been reported that fuel cell technology is available that would convert landfill gas into less harmful compounds, remove its odor causing components, avoid the need for flaring, and produce electricity. Exh. 91.5. The EIR is deficient because it does not reveal the existence of this control technology. Were the Planning and/or Zoning Departments aware of the existence of this technology at the time that the EIR was release? If not, why not? Will the Planning Department require BFI to explain why it has failed to consider the use of this technology? If not, why not? 1226 1227 1228 1229 1230 1231

The EIR does not contain an adequate analysis for mitigation measures for pollution sources other than vehicles. At a minimum, the EIR should analyze selective or non-selective catalyst reduction technology. In addition, a bag house should be required to reduce PM10 emissions. The EIR is also deficient because it does not adequately analyze the regulatory and health implications of the emission of benzene from the landfill. The EIR is also deficient because it fails to recognize the federal requirements for the developments of "best available control measures" to reduce the amount of fugitive dust and corresponding PM10 emissions from a variety of sources in the district. Exh. 92; 42 U.S.C. § 7513(b)(1). Does the Planning Department agree with the conclusions set forth in this paragraph? If not, why not. Specifically, does the Planning Department agree that the authorities cited above require BFI to use best available control methods to control PM10 emissions? If not, why not? 1232 1233 1234 1235 1236 1237 1238

According to Los Angeles County Traffic/Access guidelines, traffic count data should not be over 1-1/2 years old. Exh. 93 Wolfe Letter 1995. Does Planning and/or Zoning Staff agree that 1239

the traffic analysis criteria set forth in Exhibit 93 are valid? If not, why not?

The EIR states that BFI may use alternative daily cover on the landfill. Does the Planning Department agree that under current law, alternative daily cover may include green waste? If not, why not? There is evidence that the use of green organics for ADC will increase the organic fraction of landfills, increase the production of landfill gas, increase the migration of landfill gas, and promote landfill fires; for this and other reasons twenty-three states have banned green waste from landfills. Exh. 94. The City Manager of Glendale, Arizona is reported to have stated that that city wants to encourage the diversion of green waste from landfills because that will result in a reduction in landfill gas production. Exh. 95. A spokesperson for the operator of the waste collection system for Villa Park, California is reported to have stated that depositing green waste into landfills would "produc[e] methane gas, which adds to the global warming." Exh. 96; see also Exh. 97. The EIR is deficient because it does not reveal the harmful effects of using green waste as daily cover. Was the Planning Department aware at the time of the release of the EIR of the reported harmful environmental effects of using green waste as daily cover? If not, why not? Does the Planning Department agree with the points made regarding green waste in Exhibits 92 through 97? If not, why not? 1240 1241 1242 1243 1244 1245 1246 1247

The EIR is deficient because it does not reveal that, according to an article in the Journal of Environmental Health, surveys have been conducted which indicated that even where cities have programs to encourage residents to remove household hazardous waste ("HHW") from the municipal waste stream, "significant quantities of HHW are being improperly disposed of." Exh. 98 (Journal of Environmental Health 1997). Was the Planning Department aware of the existence of these surveys at the time the EIR was released? If not, why not? According to the same article, the California Air Resources Board concluded that "the overall composition of landfill gases from hazardous and non-hazardous sites appear to be similar," and that "non-hazardous landfills may contain concentrations of toxic gases equal to or exceeding those of hazardous landfills." Was the Planning Department aware of the existence of the Air Resources Board's findings at the time the EIR was released? If not, why not? Does the Planning Department agree with the Air Resource's Board's findings and conclusions with respect to this issue? If not, why not? According to the same article (Exh. 98), "[r]ecent data indicate that volatile organic compounds commonly found in 1248 1249 1250 1251 1252 1253

landfill leachate can rapidly migrate through synthetic liners . . . ." Was the Planning Department aware of the existence of this recent data at the time the EIR was released? If not, why not? Does the Planning Department agree that there is recent data showing that VOC's can migrate through synthetic liners? If not, why not? The EIR is deficient because it does not discuss the additional mitigation measures that are needed to deal with the problems discussed in this paragraph. 1254 1255 1256

Page 2-86 of the EIR states that the landfill will be "operational 16 hours per day," Monday through Saturday. Page 1-60 of the EIR states that "landfill operations shall be limited to the hours of 6:00 p.m. to 6:00 p.m.," Monday through Friday, and 7:00 a.m. to 2:00 p.m. on Saturday. A distinction should be made between landfilling operations and the acceptance of waste. At the very least, it should be made clear that waste will not be accepted at the landfill 16 hours per day. 1257 1258

The EIR states that the locations of transfer stations "ha[ve] not been identified" (p. 1-14), but also states that transfer trucks will constitute most of the traffic to the landfill site. BFI should be required to identify the transfer stations that will be used. If trucks smaller than transfer trucks will in fact constitute most of the traffic to the landfill site, the only reasonable conclusion to be drawn is that there will be more truck traffic, and BFI should be required to submit new traffic estimates based on the increased truck traffic. 1259 1260

Why was the EIR sent directly to homeowner organizations located several miles from the landfill, but not sent directly to (1) the North Valley Coalition, (2) the Community Advisory Committee for the County Portion of the Sunshine Canyon Landfill? Why did Planning Staff refuse to honor requests from representatives of the North Valley Coalition and the Community Advisory Committee for copies of the EIR? Why wasn't the EIR made available in an electronic format? Was the Planning Department aware that the time the EIR was released that environmental impact reports are now being made available electronically (see Exh. 99)? If not, why not? Does the Planning Department agree that the policy of encouraging community responses to environmental impact reports is disserved by limiting the distribution of copies of the reports, or by refusing legitimate requests for copies of the documents? If not, why not? Does the Planning Department agree that making the EIR electronically available would facilitate greater community participation in the EIR review process? If not, why not? 1261 1262 1263 1264 1265 1266

Does Planning and/or Zoning Staff agree that BFI received numerous extensions from the City of Los Angeles during the process of preparing the EIR? If not, why not? Does Planning and/or Zoning Staff agree that BFI continued to receive such extensions even after litigation relating to the expansion of the County portion of the landfill was resolved? If not, why not? If Planning and/or Zoning Staff agrees that BFI received several such extensions, why did it refuse the 90 day extension requested by Councilmember Hal Bernson, as discussed in the letter from Mary Edwards to Con Howe attached as Exhibit 100 (a response to Exhibit 100, if not already provided, is again requested). 1267 1268 1269

According to a draft letter on Planning Department letterhead dated December 20, 1995 and prepared for Ms. Shigeta's signature, and obtained through a request for public records, as of 1995 ERS staff was concerned that a data base submitted by BFI on June 19, 1995 1270

> created a false sense of urgency which avoided a careful analysis of alternatives to the Sunshine Canyon Landfill. In that, the data base was inclined to advocate for the proposed project by stating that all other alternatives had greater impacts than the proposed landfill.

Exh. 101. Please set forth in detail the facts which caused the ERS staff to conclude that BFI's database created a false sense of urgency, identify any corrections or revisions made to the data base which resulted in a conclusion that the data base no longer created a false sense of urgency, and identify all persons involved in the decision to conclude that the data base no longer created a false sense of urgency. 1271 1272 1273

REPORT:
GEOSYNTHETIC LINER SYSTEMS FOR MUNICIPAL SOLID WASTE LANDFILLS: AN INADEQUATE TECHNOLOGY FOR PROTECTION OF GROUNDWATER QUALITY? By G. Fred Lee, and Anne Jones-Lee, 27298 E. El Macero Dr., El Macero, California 95618-1005, U.S.A.

The geosynthetic liner system technology is an engineered containment system for use in lined "dry tomb" landfills in which are placed untreated municipal solid waste (MSW). The "dry tomb" landfilling approach relies on a cover system, to in theory, keep the wastes dry and a liner system (liner and leachate collection and removal system) to collect and remove leachate. The performance of a "dry tomb" landfill depends on the functioning of the cover and of the liner system for as long as the wastes represent a threat.

Review articles on this subject, e.g. Fluet *et al.*, suggest that flexible membrane liner systems of the type being constructed today in municipal solid waste landfills will protect groundwater quality from pollution by landfill leachate. Critical examination of the Fluet *et al.* (1992) review article, however, reveals that they omitted from their discussion whether the liner system will prevent groundwater pollution for as long as the wastes represent a threat to groundwater quality.

The incorporation of liners or liner systems of any kind into landfill designs was born from the knowledge that landfills generate leachate that will pollute the groundwater with which it comes in contact. Therefore, a review of the ability of geosynthetic liner systems to prevent the pollution of groundwater for as long as the wastes represent a threat is the major essential aspect of a review of that technology. In their abstract, Fluet *et al* made observations about the common discrepancy between meeting design guidelines of regulations and the achievement of protection of groundwater quality. The paper itself, however, focused on the design components of a geosynthetic liner "system" without adequate consideration of the realities of the use of such systems in landfill applications and the manner in which such systems will eventually fail to protect groundwater quality. The review should be recognized as missing that critical component.

Presented below is a discussion of key issues that should be considered in evaluating the efficacy of a proposed landfill liner system.

Regulatory requirements

Fluet *et al.* (1992) noted in their abstract regarding regulatory requirements,

> "Regarding regulatory considerations, the paper discusses how liner systems must be selected and designed in conformance with regulatory performance standards in order to ensure long-term protection of the environment, and notes that many American state regulations for municipal waste landfills include minimum design guidelines that may be inadequate to meet the state's performance standards."

Note. This report is an expansion to G. Fred Lee's letter to the Editor published in *Waste Management & Research* 11(1), p. 90, February 1993.

The US EPA October 9, 1991 Subtitle D regulations governing municipal solid waste landfills stated with regard to performance standards,

> "The rule's standard requires that an approved State's program be capable of protecting ground water that is currently used or reasonably expected to be used for drinking water at the relevant point of compliance [i.e., ≤150 m from waste management unit boundary on land owned by the owner of the unit]."

Those regulations also stated,

> "The design must ensure that the concentration values listed in Table 1 of this section will not be exceeded in the uppermost aquifer at the relevant point of compliance . . ."

The US EPA also specified that the landfill liner and cover shall consist of a composite liner, the uppermost component of which must be a 30 mil (7.6 mm) (minimum) flexible membrane liner (FML) and the lower component of which must be at least a 2 ft (0.6 m) layer of soil compacted to achieve a hydraulic conductivity of no more than 1×10^{-7} cm sec^{-1}. If the FML is high density polyethylene, it must be at least 60 mil (15.2 mm) thick. The FML component must also be installed in direct and uniform contact with the compacted soil component.

The state of California Chapter 15 regulations governing municipal solid waste landfills require that the landfill containment system be sufficient to protect groundwater quality for as long as the wastes represent a threat. Lee *et al* (1991) have reviewed the potential threat that municipal solid wastes and their leachates represent to the use of groundwaters for domestic water supply. The following conclusions were evident

- MSW and its leachates contain a wide variety of chemical constituents in high concentrations that can readily render a groundwater and associated aquifer unsuitable for domestic water supply purposes.
- A small amount of MSW leachate can pollute very large amounts of groundwater rendering them unusable for domestic water supply purposes.
- Due to the large amounts of unidentified, unscrutinized, unregulated non-conventional pollutants in MSW leachate, any contamination of a groundwater by MSW leachate should cause the groundwater to be considered unsuitable for domestic water supply use.
- Inorganic salts, heavy metals, non-degradable organics and non degradable organic residues associated with leachate from lined "dry tomb" MSW landfills will represent a threat to groundwater quality indefinitely.
- MSW will be a threat to groundwater quality for as long as it remains buried, and hence engineered groundwater protection systems must function properly forever in order to achieve long-term protection of groundwater quality.

While the US EPA municipal landfill regulations address only a few so called "hazardous chemicals" in groundwater, the state of California requires protection of groundwater quality from all chemicals that can impair its uses. Total dissolved solids (TDS), hardness, alkalinity, chloride, sulfate, etc. present in MSW leachate can readily pollute groundwaters, impairing their use. While the US EPA regulations do not prohibit impairment from those types of pollutants, the state of California regulations do.

The authors agree with the Fluet *et al.* (1992) observation that a geosynthetic or any other type of liner system that is used for municipal solid waste landfills needs to achieve the performance standards set forth by the regulations. At one extreme, in California

that means that the geosynthetic liner system has to provide for the unequivocal protection of groundwater quality for as long as the wastes represent a threat, i.e. forever. Fluet *et al.* (1992) also noted that the minimum design standards in many states are not adequate to achieve the performance standards. California is one such state because of the manner in which the "minimum design standards" requirement is being interpreted. The Chapter 15 regulations explicitly state that the liner (or liner system) must be capable of preventing degradation of the waters of the state, have a permeability equal to or less than 1×10^{-6} cm sec^{-1}, and be of sufficient thickness to prevent vertical migration of fluid (including waste in leachate) to the waters of the state causing degradation.

While the Chapter 15 regulations state that the minimum design standards are whatever is necessary to achieve the performance standard of groundwater quality protection, regulatory agencies have allowed landfill applicants and their consultants to interpret those regulations to mean that a liner design of a 1 ft (0.3 m) layer of soil compacted to achieve a permeability of 1×10^{-6} cm sec^{-1} is the design standard for municipal landfills. It may therefore be concluded that even where the regulations make it clear that the performance standards shall be achieved, the implementation of the regulations at the regional or local level may well not provide that degree of protection envisaged.

In many places there is a current and growing importance of groundwater for domestic supply. Once polluted with municipal landfill leachate, groundwaters and associated aquifers cannot be restored to provide a reliable water supply. It is the authors' view that the performance standards must require protection from impairment of groundwater for as long as the wastes represent a threat. Since some components of the wastes may be a threat forever, by inference the geosynthetic (or other) liner system used in a landfill must be able to perform reliably "forever" as a barrier to leachate migration through it. Any landfill liner system that does not achieve that level of protection is allowing today's society to enjoy garbage disposal for cheaper-than-real cost at the expense, in some locations, of the public health, groundwater resources and economic and other welfare of future generations.

An important observation about such well-intentioned performance standards for municipal landfills is that no material or engineered component can be guaranteed to last forever. This is especially critical for components that are buried beneath hundreds of feet or meters of garbage and/or otherwise not amenable to routine and thorough inspection, repair, and replacement. The authors have seen this dilemma "addressed" in a number of different ways, each inadequate to ensure protection of groundwater resources. Technical issues of claims such as that the wastes and hazards will "degrade," that groundwater monitoring programs will provide advance warning of pollution, that liner systems provide redundancies for protection, that only cap maintenance is of significance to groundwater quality protection, and that only "small amounts" of leachate will leak through modern liner systems, have been addressed elsewhere (Lee *et al.*, 1991, 1992*a*, 1992*b*).

Geosynthetic liner system leakage

There is a myth developing that because a "liner system" contains a number of components, none of the individual components has to be fail-safe to provide protection. In discussing the theme of their paper "the difference between "liners" and "liner systems," Fluet *et al* (1992) noted,

> "In fact, since liners depend solely on their material properties to inhibit flow of fluids through them, it is impossible to construct large scale liners that do not leak. However, this does not mean that landfills must leak, because landfills constructed with liner systems consisting of one or more liner(s) and leachate collection layer(s) can be constructed with de minimis or no leakage. Liner systems are able to succeed where simple liners fail, because, whereas liners depend solely on material properties, liner systems utilize both engineering design and material properties to prevent leakage."

There is a variety of mechanisms by which failure of not only liners but also leachate collection and removal systems will inevitably occur (Lee *et al*., 1992*a*). The integrity of most such systems is governed by the integrity of a synthetic liner, itself imperfect and subject to penetration and deterioration. Clogging of the leachate collection and removal system is another mechanism becoming recognized as problematic in maintaining their performance.

In their discussion of the role of the leachate collection systems in liner system design to "prevent" groundwater pollution, Fluet *et al.* sought to develop an analogy between the design of a landfill liner system and that of a ship's hull. There is at least one very significant difference between a ship's hull design and a landfill liner design, namely that a ship's hull is accessible for and subjected to inspection, maintenance, and repair. Further, even a well-maintained ship does not have to be kept sea worthy forever. A landfill liner is buried under often hundreds of feet (or metres) of solid wastes and cannot be inspected and cannot be repaired without waste exhumation. The landfill liner must function perfectly forever if it is going to prevent groundwater pollution for as long as the wastes represent a threat.

A considerable amount of new information has been published on landfill liner leakage. That information was recently reviewed and summarized by Lee *et al.* (1992*a*). As they pointed out, for example, Bonaparte & Gross (1990) reported,

> "Based on the data in this study, an action leakage rate of 50 lphd [litres per hectare per day] is too restrictive and presents a performance standard that, if promulgated by US EPA, frequently will not be met by facilities that were constructed to present standards with rigorous third-party CQA [Construction Quality Assurance] programs. An action leakage rate of 200 lphd appears to be reasonable for landfills that have been constructed using rigorous third-party CQA programs."

Further, the US EPA (1989) stated,

> "EPA realizes that even with a good construction quality assurance plan, flexible membrane liners (FMLs) will allow some liquid transmission either through water vapor permeation of an intact FML, or through small pinholes or tears in a slightly flawed FML. Leakage rates resulting from these mechanisms can range from less than 1 to 300 gallons per acre per day (gal/acre/day) [9 to 2800 lphd]."

In January 1992, the US EPA released its regulations regarding *de minimis* or "accepted" leakage rates for hazardous waste landfills. There seems to be general agreement that a *de minimis* leakage rate of less than 20 gals/acre/day [200 lphd] would be very difficult to achieve when the liner system is new (US EPA, 1992). US EPA (1992) did not recommend a fixed *de minimis* leakage rate.

Lee *et al.* (1992*a*) pointed out that *de minimis* leakage rates should be based on protection of groundwater quality, not on what can be routinely achieved with a particular existing technology of FML's and compacted soil liner systems. They also discussed the fact that the existing liner system materials were not selected because they have a demonstrated ability to provide groundwater quality protection for as long as wastes represent a threat. Landfills are built with the least expensive materials and

systems that will allow them to be approved by the regulators. A *de minimis* leakage rate should represent a rate of leakage that will not, under any reasonable circumstance, result in groundwater pollution that can impair the uses of the groundwater for domestic or other purposes. The establishment of *de minimis* leakage rates based on the performance of geosynthetic liner systems that can be routinely achieved is technically invalid and highly inappropriate.

It is concluded that leakage of municipal landfill leachate at a rate of 20 gal/acre/day [200 lphd] may pollute millions of gallons of groundwater daily, rendering it and the associated areas of the aquifer unsuitable for domestic water supply. Therefore, the possibility exists that after a geosynthetic liner system is put into service, it may fail to protect groundwater quality from pollution by municipal landfill leachate.

Long-term performance of geosynthetic liner systems

Fluet *et al.* (1992) did not properly address the expectations for long-term performance of FMLs and compacted soil as effective liners, or of the long-term performance of "liner systems." They simply stated in this regard:

> "Geosynthetic liner systems have performed very well and should continue to provide society with a cost effective and safe means of containing waste. The foreseeable dangers lie not with the geosynthetic liner systems but with untrained designers, careless contractors, imprudent operators and unknowledgable regulators. Any of these can result in inappropriate geosynthetic liner systems and the resulting problems reflect poorly on all of us. Let us all commit to designing, installing, operating, and approving the types of geosynthetic liner systems which will reflect well on all concerned and, most importantly, will protect the environment well into the future."

First, the issue is not protection of the environment simply "well into the future." The regulatory, and indeed the groundwater quality protection, requirements are not met by the liner system's working for a while and deteriorating sufficiently to allow widespread pollution. US (federal) requirements do not explicitly specify a performance duration, but they imply that the performance duration has no time limit on it. The state of California regulations are explicit in requiring protection for as long as the wastes represent a threat. Therefore, claiming protection "well into the future" is inadequate.

The ensuing notation of the vulnerability of groundwater quality protection components of landfill systems to "untrained designers, careless contractors, imprudent operators and unknowledgable regulators" expresses a fundamental, and fatal flaw of the "dry tomb" lined landfilling approach. While systems may be able to be conceived that should in theory protect groundwater quality *ad infinitum*, they will always be subject to human error, carelessness, and neglect. If there is vulnerability to these types of human error in the development and operation of a new landfill, they can only be assumed to multiply once the landfill is closed and the landfill company is relieved of responsibility for it or society "forgets" that the area is a landfill. However, even if the design, construction and operation of landfills with geosynthetic liner systems were to be done without error or imperfection, the liner system will, based on the Second Law of Thermodynamics, eventually fail to prevent leakage of leachate to pollute groundwater. Thus, the issues of inadequate design, construction, operation, etc. associated with geosynthetic liner systems, only speak to when groundwater pollution will occur, not to whether it will occur. The less attention to perfection in design, construction, and operation, the earlier it may be expected to fail. Pollution that does not occur for 50 years is as much of concern as pollution that occurs after 5 years.

Key findings on issue of long-term protection

Based on their review of the recent literature, characteristics of municipal solid wastes and their leachates, the characteristics and research on the long term performance of FMLs and compacted soil layers, and other liner system components, Lee *et al.* (1992*a*) drew the following conclusions about the expected performance of geosynthetic liner systems.

- Geomembrane liner systems, including those with composite liners and covers, will typically leak leachate shortly after being placed in service at a rate sufficient to pollute groundwater, impairing its use, and the use of that part of the aquifer, for domestic water supply purposes.
- The leachate retention capabilities of geomembrane liner systems will deteriorate over time, leading to an increase in the rate of leachate migration through the liner and pollution of groundwater with conventional, non-conventional, and hazardous pollutants.
- Geomembrane liner systems cannot be expected to perform indefinitely – i.e. prevent groundwater pollution/for as long as the waste represents a threat to groundwater quality.
- Geosynthetic liner systems are often designed, constructed, and operated at the lowest cost possible. Once a landfill is put into service, there is no opportunity to inspect, repair, or replace system components as they deteriorate or fail. Therefore, the system components must function perfectly.
- The geomembrane liner systems of the type being used today, including those with double-composite liner systems, are a flawed technology that will not provide for groundwater quality protection from pollution by municipal landfill leachate.

Liner reviews, such as the recent work by Fluet *et al.*, should discuss the ability of geosynthetic liner systems of the type they describe to prevent unequivocally groundwater pollution for as long as the wastes represent a threat. Since it is agreed these systems cannot be relied upon to provide that level and duration of protection, they must be considered to be a flawed technological approach. Geomembrane liner systems have not performed well, nor would they be expected to provide the necessary protection of groundwater quality.

RESEARCHERS INVESTIGATE VAPOR PHASE AS SOURCE OF LANDFILL CONTAMINATION

Investigators are uncovering evidence that may help explain situations where landfills generate small amounts of leachate or where ground water contamination does not closely parallel leachate composition. Traditional studies of contaminants migrating from landfills have focused primarily on leachate transported in the liquid phase to ground or surface waters.

Waste constituents are likely leaving the landfill in the vapor phase in addition to, or in place of, the liquid phase, according to John Ward, a senior hydrogeologist with Hydro Geo Chem Inc. of Tucson, Ariz. He says his studies of this phenomenon at landfills in Arizona and California have produced interesting results.

Ward states that many of these landfills were constructed between the early 1960s and the early 1980s and probably have achieved a steady state with their surroundings. Therefore, sampling ground water or leachate over a short timeframe yields less insight into the mechanisms of contaminant transport than the spatial distribution of the contaminants both in the liquid and vapor phases.

At some sites, soil-gas samples have been collected both within and beneath waste. The results indicate that there was virtual saturation of methane and that levels remained as high as 20 percent saturation at depth. Concentrations of volatile organic compounds in soil gas tended to increase with depth, although there were essentially no VOCs in the landfill gas. These landfills had little to no leachate, but nearby ground water exhibited chemical constituents that could be linked to the landfill.

Ward believes there may be several explanations. The simplest is that VOC leachate left the landfill and moved into nearby ground water. In addition, VOCs may be migrating in the vapor phase upward from ground water, which would make their concentrations higher at the surface of the water table than at the bottom of the fill. Field data did not support this explanation however, Ward adds.

The more likely explanation, he says, has not been studied in detail but seems more consistent with field data. The methane could drive VOCs from the landfill and into surrounding soils, according to Ward. He has seen this occur at an expansion of a landfill, where the liner cut off the methane's escape route and the additional weight appeared to squeeze the gas from the bottom fill, driving VOCs with it.

Researchers at Hydro Geo Chem have modeled the vapor- phase transport process through advection and diffusion simulations, both coupling and decoupling methane. "It's essentially modeling a soil-vapor extraction system in reverse," Ward explains. "When only diffusive transport of VOCs is modeled, it doesn't account for what is seen in the ground water or soil gas."

Model results suggest the data are consistent with long- term vapor-phase migration, both through the landfill surface to the atmosphere and through the vadose zone to the ground water, Ward says. Additional research needs to be completed before it can be applied to the investigation of landfills and their impact on ground water resources, he adds. For more information, call Ward at (800) 727-5547.

Prospects for Larger or More Frequent Earthquakes in the Los Angeles Metropolitan Region

James F. Dolan,* Kerry Sieh, Thomas K. Rockwell, Robert S. Yeats, John Shaw, John Suppe, Gary J. Huftile, Eldon M. Gath

Far too few moderate earthquakes have occurred within the Los Angeles, California, metropolitan region during the 200-year-long historic period to account for observed strain accumulation, indicating that the historic era represents either a lull between clusters of moderate earthquakes or part of a centuries-long interseismic period between much larger (moment magnitude, M_w 7.2 to 7.6) events. Geologic slip rates and relations between moment magnitude, average coseismic slip, and rupture area show that either of these hypotheses is possible, but that the latter is the more plausible of the two. The average time between M_w 7.2 to 7.6 earthquakes from a combination of six fault systems within the metropolitan area was estimated to be about 140 years.

Californians have long anticipated the recurrence of the "Big One," a great earthquake ($M \sim 8$) emanating from a long section of the San Andreas fault (SAF), such as occurred in 1857 and 1906. Consequently, earthquake hazard assessment and preparedness in southern California has historically focused primarily on the SAF and its various strike-slip branches (Fig. 1) (*1*, *2*). In the past decade, however, several moderate earthquakes have occurred on faults beneath the Los Angeles metropolitan area. Moderate to large earthquakes (M_w 6.5 to 7.5) on these faults could potentially cause even more damage than a much larger earthquake on the more distant SAF. This was dramatically demonstrated by the 1994 M_w 6.7 Northridge earthquake, the second most expensive natural disaster in U.S. history (after Hurricane Andrew) (*3*).

The Los Angeles region is geologically complex, and almost 100 active faults have been identified in the area (*4*–*8*). Because of their size and proximity to major population centers, six major fault systems are of particular concern (*9*–*12*).

1) The Sierra Madre–Cucamonga system extends for 100 km along the northern edge of the densely populated San Fernando and San Gabriel valleys (*13*, *14*). The westernmost 19 km of the north-dipping Sierra Madre fault zone (including the San Fernando fault) ruptured during the 1971 M_w 6.7 Sylmar earthquake, which claimed 64 lives and caused $558 million in damage (1971 dollars; ~$2 billion in 1994 dollars) (*15*).

2) The Los Angeles basin fault system comprises two major blind thrust fault ramps (Elysian Park and Compton ramps) that are connected by a mid-basin flat fault segment (*7*, *16*). The Whittier fault (*17*) and the northern Newport-Inglewood fault zone (*4*, *7*) may represent partitioned strike-slip faults above the blind thrust faults. This system underlies the most densely urbanized part of the region, including downtown Los Angeles.

3) The Santa Monica Mountains fault system, which extends for 90 km from near downtown Los Angeles westward along the Malibu Coast, consists of a large blind thrust ramp and the surficial Hollywood–Santa Monica–Malibu Coast subsystem, which we interpret as a set of predominantly left-lateral strike-slip faults (*4*, *5*, *16*, *18*–*20*).

4) The Oak Ridge fault system is a major south-dipping thrust system that extends for more than 70 km from just east of Ventura to at least the eastern end of the Santa Clarita River Valley (*21*, *22*). A previously unrecognized, blind eastern extension of this system appears to have been responsible for the 17 January 1994 M_w 6.7 Northridge earthquake (*8*).

5) The San Cayetano fault, which dips moderately northward, extends for 40 km along the northern boundary of the oil-rich Ventura basin (*23*). The eastern part of this fault exhibits one of the highest slip rates in the region (7.5 to 10.4 mm year^{-1}) (*23*).

6) The Palos Verdes fault, which is best known from its onshore extent along the northeastern edge of the Palos Verdes Peninsula in the southwestern part of the Los Angeles basin, also extends as a submarine feature for more than 50 km to the south of the peninsula (*24*). Recent studies indicate that the Palos Verdes fault is slipping at a rate of approximately 3 mm year^{-1} (*25*).

The large number of damaging, moderate ($4.8 \leq M_w \leq 6.7$) earthquakes that have occurred in the Los Angeles region

Operators use piggyback concept to meet regs. (use of piggyback landfill by solid waste managers)

Robert, Jr. Hauser

Federal mandates to close unlined landfills have inspired renewed interest in one innovative concept -- the piggyback landfill.

To site today's landfills, solid waste managers must balance regulatory requirements, public opposition and landfill capacity. The piggyback approach, which constructs a new landfill on top of one that is either closed or scheduled to be closed, can help to meet those needs. Mother configuration is to construct the new landfill adjacent to the closed landfill, using the side slope as part of the new landfill. With both methods, the piggyback landfill allows for vertical and/or horizontal expansion at an already-approved site.

The piggyback landfill's primary advantage is that municipalities can create more landfill space without a rigorous siting process. Also, the expenditure to cap a landfill can be incorporated into the liner system of the piggyback landfill and offset some closure costs. Communities also can avoid hauling expenses for moving MSW to a new, more remote site.

Piggyback landfills may sound ideal in theory, but there are still concerns about building a new landfill on top of existing solid waste. Since the MSW settles as it biodegrades and shifts under the weight of the new waste, the former landfill's instability can threaten the integrity of a new liner system.

Landfill engineers have developed techniques to curtail settlement. Deep dynamic compaction, or dropping a weight to compact the existing waste prior to new construction, reduces the magnitude of future settlement. An earth preload works in a similar manner but relies on the weight of a soil fill. However, both of these alternatives are only effective on compacting materials to a depth of approximately 40 feet, and a deeper, more active landfill may not be adequately compacted.

Injecting slurry grout, a costly but effective technique, fills the voids within a landfill and hardens to strengthen the foundation of new landfills. To improve the sub-grade and to protect the new liner system, the liner can be reinforced with geogrids, which are layers made of various plastics. This support method is helpful to prevent damage from decaying appliances and vehicles. A rusted refrigerator, for example, can cause the liner to dip and put stress on the liner containment system.

A piggyback landfill is not recommended for existing sites with leachate and groundwater contamination problems since it would be difficult to determine if the source of the problem was the old or the new landfill.

Even as engineers develop technology to support piggyback landfills, regulators remain cautious about approving piggyback landfills due to long-term performance uncertainties. As landfill engineers and regulators learn more about landfill settlement and the related issues, piggyback landfills are expected to gain more support.

Long-term monitoring of existing piggyback landfills such as the Blydenburgh landfill, Islip, N.Y., the Brookhaven landfill, Long Island, N.Y., the Oaks sanitary landfill, Montgomery County, Md., and a landfill in St. Lucie County, Fla., that is situated adjacent to a closed landfill and uses its side slope, will determine if piggyback landfills will be viable for the future.

since 1971 has given rise to the perception that this earthquake frequency is typical of the area. In reality, however, few large earthquakes have occurred on faults within the metropolitan region during the two centuries of historic record, the two largest being the M_w 6.7 Northridge and San Fernando events of 1994 and 1971, respectively [25–30].

Geodetic studies indicate a shortening rate across the Transverse Ranges in the greater metropolitan region of approximately 9.5 mm year^{-1} (31). These data suggest that far too few moderate earthquakes have occurred within the region to account for observed strain accumulation, indicating that a deficit of seismic energy release exists in metropolitan southern California (32).

In this article we use reasonable geologic slip rates for the known active faults within the metropolitan area, together with newly determined local relations between moment magnitude (M_w), average coseismic slip, and rupture area, to attempt a quantitative assessment of the potential for future destructive earthquakes from faults within the Los Angeles metropolitan region (12). We compare the rate of historical seismic moment release with longer term rates derived from geologic data to quantify the historical earthquake deficit. We then propose two end-member scenarios. In the first scenario, strain is released in numerous, moderate, Northridge-like earthquakes. In the second, strain is released in less frequent but much larger (M_w 7.2 to 7.6) earthquakes. Geological slip rates allow us to estimate repeat times for earthquakes in each of these scenarios.

Source Parameters

Moment magnitude can be empirically related to known geological parameters, such as rupture area (A) and average co-

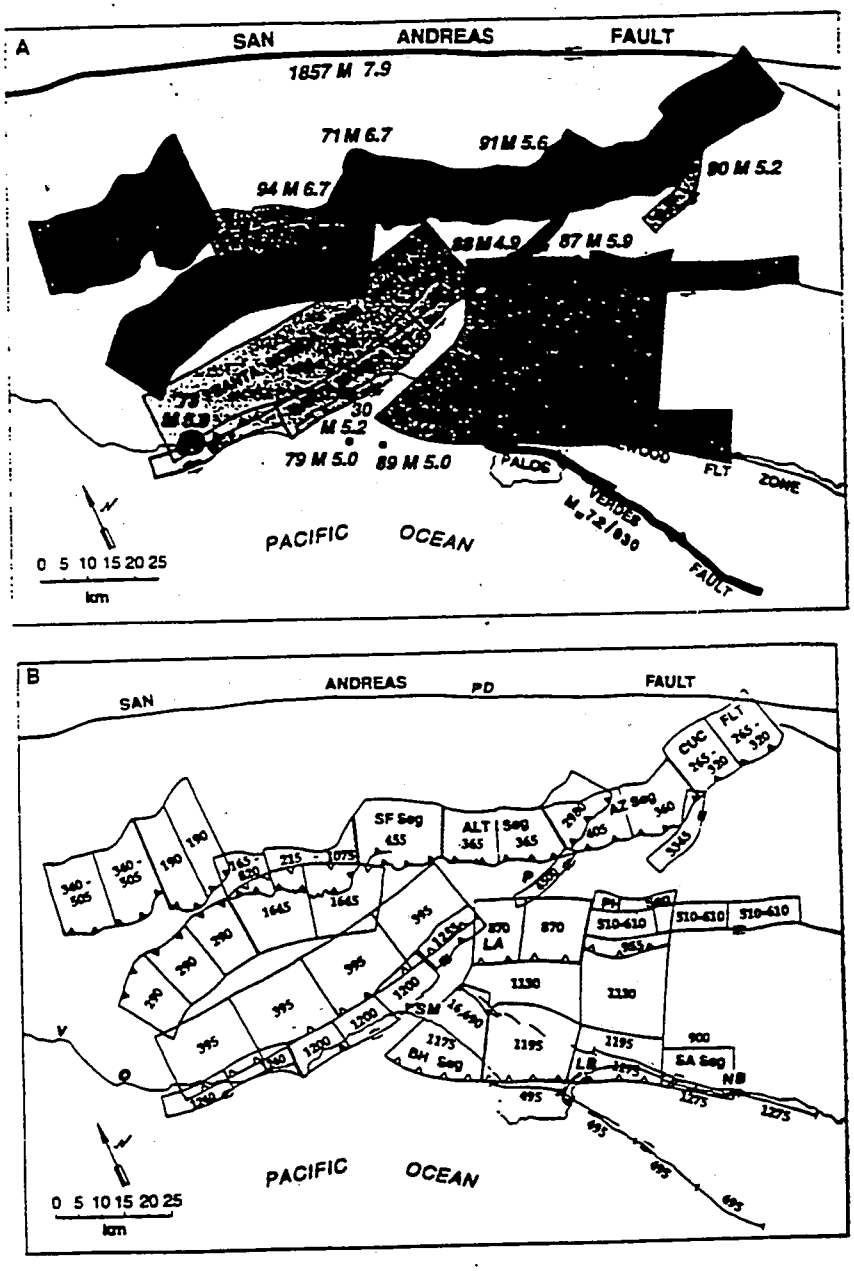

Fig. 1. (A) Historical earthquake ruptures and proposed large earthquake sources within the greater Los Angeles metropolitan area. Black areas denote surface projections of rupture planes of selected moderate historic earthquakes (6, 35–40, 65–67). Date and magnitude (M_w) of each earthquake are also shown. Historic ruptures on vertical strike-slip faults (1857 and 1933 earthquakes) are shown as heavy black lines. Polygons represent map projections of nonvertical fault planes. Thin lines denote near-vertical faults. Intermediate-width lines outline major fault systems that we consider could cause large earthquakes (M_w 7.2 to 7.6). Solid barbs denote thrust faults that break the surface; barbs point downdip. Open barbs represent the upper edge of blind thrust fault ramps; barbs point downdip. Predominantly strike-slip faults are shown by double arrows along the surficial trace of each fault. Maximum credible earthquakes and their average recurrence intervals are shown for each fault system (for example, M_w 7.4/1010 on the Sierra Madre system indicates a recurrence interval of approximately 1010 years for a M_w 7.4 earthquake rupturing the entire system). Comp FLT, Compton fault; C-SF, Clamshell-Sawpit fault; HF, Hollywood fault; MCF, Malibu Coast fault; RF, Raymond fault; SJF, San Jose fault; SSF, Santa Susana fault. (B) Map showing the 51 potential, moderate (M_w 6.5 to 6.9; average M_w 6.7) earthquake sources within the metropolitan region that we used in our moderate-earthquake scenario. The number within each earthquake source area denotes the approximate average recurrence interval (in years) for a moderate earthquake from each source region. In this scenario, for example, the source of the Northridge earthquake produces a M_w 6.7 event every 1645 years. Double lines denote geologically reasonable segment boundaries. ALT Seg, Altadena segment; AZ Seg, Azusa segment; BH Seg, Baldwin Hills segment; CUC FLT, Cucamonga fault; LA, downtown Los Angeles; LB, Long Beach; NB, Newport Beach; O, Oxnard; P, Pasadena; PD, Palmdale; PH Seg, Puente Hills segment; SA Seg, Santa Ana segment; SF Seg, San Fernando segment; SM, Santa Monica; V, Ventura.

seismic displacement over the rupture plane (D). Several compilations of parameters have been published, most of them for a worldwide earthquake data set [for example, (2, 33, 34)]; however, these relations can depend on geographic location and tectonic setting. Therefore, we have constructed new regressions of M_w versus rupture area and average coseismic slip using data from eight well-studied, off–San Andreas southern California earthquakes that have occurred since 1932 (Fig. 2 and Table 1) (35–41). We converted seismic moments (M_o) for the eight earthquakes to M_w using the equation $M_w = (\log M_o - 16.1)/1.5$ (42).

The regression (Fig. 2A) shows that for a given rupture area, M_w for a southern California earthquake will be larger than would be expected from the regressions on worldwide data. The discrepancy is larger for smaller events, ranging from about 0.3 units for $M_w = 5.0$ to about 0.1 units for $M_w = 7.5$.

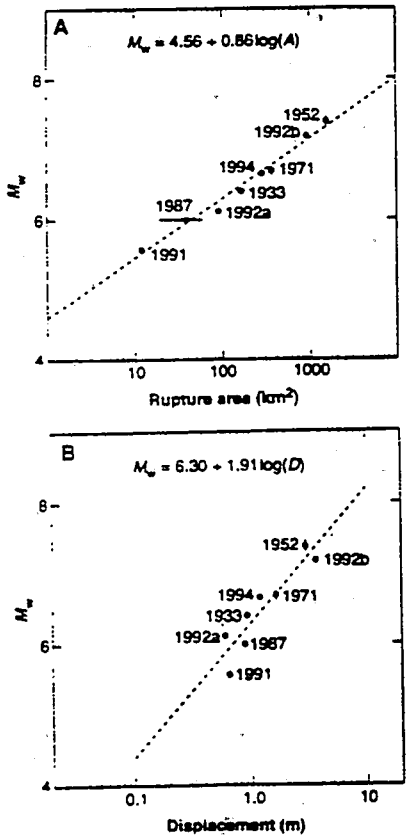

Fig. 2. New regressions for southern California earthquake parameters. (A) Rupture area (square kilometers) plotted as a function of moment magnitude (M_w) for southern California earthquakes (Table 1). Data sources as in (35–40). (B) Moment magnitude versus average slip over the rupture plane for southern California events was determined by solving the equation $M_o = \mu AD$.

From the equation above and the definition of seismic moment, $M_o = \mu AD$, where μ = shear rigidity, we can determine the relation between M_w and D (Fig. 2B) (43). The relation for southern California contrasts markedly with that of the global data (34). Displacements for small southern California earthquakes are larger than would be expected, whereas displacements for large events ($M_w > 7.4$) are smaller than expected.

Geologically Reasonable Scenarios

Recent advances in understanding the active tectonics and structure of the Los Angeles region, particularly the identification of large thrust fault systems beneath the metropolitan area, have led to a more complete understanding of potentially seismogenic faults of the region (5–7). To construct geologically realistic earthquake scenarios based on these data, we used the location, extent, and dip of seismogenic faults, together with the depth of the base of the seismogenic zone as determined from the base of deepest seismicity (44), to determine fault plane area. We then used the new regression equations for southern California earthquakes to determine the moment magnitude and average displacement of postulated earthquakes on each fault (Table 2). The recurrence interval for a particular earthquake is then the average slip estimate for each fault or fault segment divided by the geologically determined slip rate of the fault (45).

Moderate-Earthquake Scenario

One means of quantifying the historical earthquake deficit is to assume that all strain across the region is released uniformly during moderate ($M_w \sim 6.7$) earthquakes (46). For this scenario we determined geologically reasonable segment boundaries for all structures (Fig. 1B) (47). We then arbitrarily divided the segments defined by these boundaries into M_w 6.7–sized subsegments (Fig. 1B). Because subsegment size is ultimately controlled by the geologically defined segments, which are not identical in size, the resulting moderate earthquake sources range from 175 km² (M_w 6.5) to 397 km² (M_w 6.8). This process results in 51 moderate (average M_w 6.7) earthquake sources within the greater Los Angeles metropolitan area (Fig. 1B).

We converted the recurrence interval (RI) for each source into an expected earthquake frequency (f), such that $f = 1/RI$. Taking the inverse of the sum of the frequencies for all 51 sources yields an average expected repeat time for M_w 6.7 earthquakes of about 11 years, assuming that all strain across the region is accommodated in such events. Uniform release of strain in M_w 6.7 earthquakes thus requires that between 13 and 17 moderate earthquakes should have occurred during the historic period. Only two such events have been recorded (26, 27), indicating that there is a historical deficit of 11 to 15 M_w 6.7 earthquakes. Fifteen M_w 6.7 earthquakes correspond to a cumulative stored seismic moment of 2.12×10^{27} dyne cm, which is equivalent to a M_w 7.5 earthquake.

Large-Earthquake Scenario

In this scenario, we assumed that all strain across the Los Angeles region is released during large (M_w 7.2 to 7.6) earthquakes and that each of the six major fault systems described in the introduction fails in its own characteristic earthquake (48). For the four single-fault systems (Sierra Madre–Cucamonga, Oak Ridge, San Cayetano, and Palos Verdes), we used the total area of each fault to calculate a moment magnitude, which we then used to calculate the average coseismic slip for each earthquake (Table 2).

The two remaining large fault systems (Santa Monica Mountains and Los Angeles basin) involve multiple faults with varying slip rates and slip directions (49). Unlike the four single-fault systems, strain is partitioned on the Santa Monica Mountains and Los Angeles basin systems such that dip-slip

Table 1. Parameters for historical southern California earthquakes (35–40).

Earthquake	M_o	M_w	Rupture area (km²) min–max (avg)	Average slip (cm)
1933 Long Beach	5×10^{25}	6.40	150–180 (165)	84–101
1952 Kern County	1×10^{27}	7.29	1450–1625 (1540)	196–400
	1.9×10^{27}	7.45		
	2.0×10^{27}	7.47		
1971 San Fernando	1.0×10^{26}	6.60	360	87–143
	1.7×10^{26}	6.75		
1987 Whittier Narrows	1.0×10^{25}	6.00	20–60 (40)	34–142
1991 Sierra Madre	2.8×10^{24}	5.57	12	65
1992a Joshua Tree	1.9×10^{25}	6.12	90	60
1992b Landers	7.5×10^{26}	7.18	910	330–404
1994 Northridge	1.2×10^{26}	6.65	280	119

motion is accommodated along the blind thrust faults, and strike-slip motion is accommodated along the surficial strike-slip faults. Therefore, we treated these different subsystems independently and calculated sizes and recurrence intervals for earthquakes occurring on each of these individual structures. Adding the moments of these individual subevents yields the overall size of the maximum credible earthquake on each system (50).

Our calculations indicate (Fig. 1A) the following: (i) The Sierra Madre–Cucamonga system is capable of producing a M_w 7.4 earthquake approximately every 980 to 1040 years. (ii) Rupture of the Santa Monica Mountains blind thrust fault would produce a M_w 7.2 earthquake about every 740 years, whereas the Hollywood–Santa Monica–Malibu Coast fault system could independently produce a M_w 7.3 earthquake approximately every 2195 to 3290 years. If these subsystems were to rupture together, they would generate a M_w 7.5 earthquake. (iii) If only the blind thrust faults of the Los Angeles basin system were to rupture, they would produce a M_w 7.5 earthquake about every 2845 years. The Whittier fault is capable of independently producing a M_w 7.1 earthquake about every 840 to 1005 years. If the Whittier fault and the blind thrust faults were to rupture together, they could produce a M_w 7.6 earthquake. Although it is possible that the northern Newport-Inglewood (N-I) fault could rupture together with both the blind thrust faults and the Whittier fault, the extremely long recurrence interval that we calculate for the N-I fault indicates that this would be a very rare event. (iv) The Oak Ridge system is capable of generating a M_w 7.3 earthquake approximately every 1010 years. (v) Rupture of the entire San Cayetano fault would produce a M_w 7.2 earthquake every 455 to 545 years. (vi) The Palos Verdes fault could generate a M_w 7.2 earthquake approximately every 925 years.

The collective average recurrence interval for the seven large (M_w 7.2 to 7.5) earthquakes that we propose on these six systems is about 140 years (51), a return time comparable with that of $M \sim 7.8$ to 7.9 earthquakes on the San Andreas fault (52, 53). Within the Los Angeles region the historic record, which for M_w 7.2 to 7.6 earthquakes is probably complete as far back as the early 1780s (26, 27), is devoid of such large earthquakes. Thus, it has been at least 210 years since the most recent large earthquake in the Los Angeles region, a time interval that is longer than the average recurrence interval that we calculated for large earthquakes.

The two scenarios discussed above represent reasonable end-member possibilities for strain release. However, the actual means of strain release within the Los Angeles region is undoubtedly more complex, with some combination of moderate and large earthquakes (Table 2). Hough (54), for example, suggests a fractal distribution of earthquakes in which most seismic moment release is concentrated in infrequent, large events.

Table 2. Parameters for large scenario earthquakes rupturing entire fault systems and for intermediate-sized earthquakes rupturing parts of fault systems. N/D, not determined.

Implications for Seismic Hazards

These scenarios indicate that there is a marked deficit in moment release in the greater Los Angeles metropolitan area during the 200-year historic period; geologic fault slip rates and geodetic shortening rates show that we have had far too few earthquakes to account for strain accumulation. There are three possible explanations for this observation. (i) A significant portion of strain is released aseismically. (ii) Most of the strain is released in moderate earthquakes. (iii) Much, or most, of the strain is released in much larger earthquakes (M_w 7.2 to 7.6) with longer recurrence intervals.

There is no evidence that any significant aseismic fault creep occurs within the brittle, upper crust of the Los Angeles metropolitan region. If aseismic creep were occurring, we would expect to see abundant microseismicity on major thrust fault ramps as well as extensive disruption of built structures where they lie atop surficial faults or the traces of active folding above blind thrust faults (55). Neither phenomenon has been observed in the metropolitan area. If no significant fault creep occurs in the region, then fault slip must be accommodated during earthquakes.

If all strain release occurs during moderate, M_w 6.7 earthquakes, then the historic period must represent a lull between clusters of such earthquakes. The average 11-year recurrence interval for M_w 6.7 earthquakes on the 51 sources we have defined predicts that 17 such events should have occurred during the past 195 years, but we have experienced only two such events. Elsewhere in the world, temporal and spatial clusters of destructive earthquakes have been observed at decade-long time scales along both thrust faults (for example, Coalinga–Kettleman Hills, California, 1982–85) and strike-slip faults (for example, North Anatolian fault, Turkey, 1939–44) (56). Therefore, we cannot rule out the possibility that much of the accumulated strain in the Los Angeles metropolitan region could be released by a cluster of moderate earthquakes. Given the level of damage from the Northridge earthquake, such a sequence would certainly strain the ability of the region (and the nation) to absorb the resultant losses.

Paleoseismologic data are too sparse and incomplete to tell us when the most recent large earthquake occurred in the Los Angeles area. However, data from several faults suggest that large earthquakes may indeed have occurred in the region. For example, recurrence interval data from excavations across the Santa Monica, Hollywood, and Malibu Coast faults indicate that these faults have ruptured during Holocene time, but that the most recent surface-rupturing earthquakes occurred several thousand years ago (19, 20). Furthermore, average recurrence intervals for the Santa Monica and Malibu Coast faults determined during trench studies (19) are approximately 3000 to 5000 years, far longer than would be expected if these faults ruptured individually (Table 2). Similarly, occurrence of the most recent surface-rupturing earthquake on the Hollywood fault more than 2000 to 4000 years ago (20) indicates a much longer period than would be expected if the Hollywood fault ruptured by itself during moderate earthquakes (Table 2). These data, although not definitive, suggest that the surficial faults of the Hollywood–Santa Monica–Malibu Coast system rupture in conjunction either with each other or with other faults. The Santa Monica Mountains blind thrust fault, which may be mechanically linked to the surficial faults at depth, may well rupture with these surficial faults during large earthquakes.

Similarly, paleoseismologic data from the Whittier fault suggest that this fault has ruptured in combination with other faults in the past. These data reveal a recurrence interval of approximately 1700 years for surface-rupturing earthquakes (17), considerably longer than the repeat time of 875 to 1050 years that we calculate for a M_w 7.1 earthquake generated by rupture of only the Whittier fault (Table 2). The Whittier fault may rupture together with either the northern Elsinore fault (57) or the Elysian Park blind thrust (7).

These data indicate that events such as those proposed in our large-earthquake scenario (M_w 7.2 to 7.6) may have occurred in the Los Angeles metropolitan region in the past and may recur in the future. Similar tectonic regimes elsewhere in the world have produced thrust- and reverse-fault earthquakes of this size [for example, 1944 San Juan, Argentina, surface wave magnitude (M_s) 7.4; 1952 Kern County, California, M_w 7.4; 1964 Niigata, Japan, M_w 7.5; 1977 Caucete, Argentina, M_w 7.4; 1978 Tabas-e-Golshan, Iran, M_w 7.4; 1980 El Asnam, Algeria, M 7.3; 1988 Spitak, Armenia, M_w 6.9; and 1992 Suusamyr, Kyrgyzstan, M_w 7.4] (58).

We conclude that faults within the Los Angeles region are capable of generating earthquakes in the range of M_w 7.2 to 7.6. Documented examples of long-term earthquake clustering (52, 59) indicate that we could well be in the middle of a centuries-long quiescent period. However, it has been at least 210 years since such an event has occurred in the region, indicating that we are within the expected average recurrence time for an earthquake of this size, as determined by our model. The effects of such a large earthquake would be substantially different from the recent, moderate Northridge earthquake in several important respects. Specifically, a large earthquake would cause strong ground shaking over a much larger area and would have a much longer duration. Given the potentially devastating effects such a large earthquake would have on life and property in the region, we believe that Los Angeles must consider the potential for such an event in future planning scenarios.

9. We define a fault system as a set of faults that are closely linked both geographically and kinematically and which therefore might plausibly rupture together in the Los Angeles region, partitioning of oblique slip into parallel strike-slip and thrust faults occurs on several of the large fault systems in metropolitan southern California. For example, at depth the steeply dipping Whittier fault probably interacts with the Puente Hills segment of the Elysian Park thrust system, and the moderately to steeply dipping Hollywood–Santa Monica–Malibu Coast fault (HF-SMF-MCF) system must interact with the Santa Monica Mountains blind thrust fault. We hypothesize that the surficial faults accommodate the strike-slip component along these two oblique-slip systems—right-lateral in the case of the Whittier fault; left-lateral in the case of the HF-SMF-MCF system—whereas the contractional component of motion along the system is accommodated by folding and movement along the blind thrust ramps.
10. Some active fault systems have been generalized. (For example, the Elysian Park thrust system in East Los Angeles is shown as a single fault rather than as an imbricate thrust stack; known east-trending faults in this system are not used. The Verdugo Hills fault system is assumed to be part of the Sierra Madre fault zone.) Furthermore, some active faults have been intentionally omitted, either because they are (i) too poorly known [for example, (60)], (ii) too small to produce moderate earthquakes by themselves [for example, (61)], or (iii) characterized by complex slip behavior [for example, (62)]. At our present level of understanding, such generalizations and omissions are appropriate. Finally, it is possible that we have not yet identified all active faults in the region. Given the uncertainties, we tried to be conservative. The overall effect of our source and slip rate characterization is to produce a probable underestimate of the rate of strain accumulation across the Los Angeles metropolitan region.
11. The southern Newport-Inglewood (N-I) fault system, as modeled in this study, is capable of producing a M_w 7.1 earthquake. However, we arbitrarily truncated the fault at the southeastern boundary of our study area. The fault system probably continues all the way to San Diego and thus may be capable of an earthquake considerably larger than M_w 7.1. Within the metropolitan region, we distinguished the northern and southern N-I fault zones on the basis of a marked northward decrease in slip rate (7) and a pronounced change in structural style (4) at the north end of the 1933 earthquake rupture zone. We hy-

pothesize that this structural transition is caused by a northward transfer of slip westward off the N-I fault zone onto northwest-trending contractional structures and, possibly, the northern part of the Palos Verdes fault.

12. We do not consider the San Andreas and San Jacinto faults in this study.

16. The Elysian Park thrust system was originally defined as a northeast- to north-dipping blind thrust fault extending from Orange County in the southeast, through downtown Los Angeles, and westward beneath the Santa Monica Mountains along the Malibu coast to Point Mugu (5). However, our geomorphologic analysis indicates that this zone of contractional deformation actually comprises two distinct thrust fault systems, an east-west–trending thrust ramp beneath the Santa Monica Mountains that we refer to as the Santa Monica Mountains thrust fault, and a west-northwest–trending system that extends from the Elysian Park Hills northwest of Los Angeles through downtown and East Los Angeles (Los Angeles segment) and southeastward beneath the Puente Hills (Puente Hills segment) (7). Specifically, the N85E-trending eastern Santa Monica Mountains, which have developed above the Santa Monica Mountains blind thrust fault, form a well-defined, distinct topographic entity that extends for more than 5 km to the east of southwest-dipping, N65W-striking Miocene-Pliocene strata [T. Dibblee, *Geologic Map of Hollywood-Burbank (South 1/2) Quadrangle DF-30* (Dibblee Geological Foundation, Santa Barbara, CA, 1991)] that have been deformed above the northwest-striking Elysian Park thrust ramp in the Elysian Park Hills. Because of their geographic association with the Elysian Park Hills, we retain the name Elysian Park thrust fault for the Los Angeles and Puente Hills segments of the blind thrust ramp.

28. Large, historic earthquakes on the San Andreas fault (for example, 5 December 1812 and 9 January 1857) are not included in our analysis.
29. A large earthquake (M 7?) on 21 December 1812 damaged mission buildings in Santa Barbara and the western Transverse Ranges and produced a small tsunami. This event is not included in our scenario because all researchers place its position in the Santa Barbara Channel, well to the west of the western limit of our study area (26). We have also excluded the moderate earthquake of 11 July 1855 (M 6?), which damaged structures at Los Angeles and Mission San Gabriel (13 km east-northeast of Los Angeles). Although this event almost certainly occurred beneath what is now metropolitan Los Angeles, it was probably smaller than our M_w 6.7–scenario earthquakes (26).
30. Record keeping in southern California began with the establishment of Spanish missions during the late 1770s to early 1780s (26, 27). The early part of the record is of variable quality, particularly from 1832 to 1848 (27), but is certainly complete for Northridge–sized events since 1850, and is probably complete at that level since 1800 (27). The record for larger events ($M_w \geq 7.2$) is probably complete for the region since the earliest mission records (27).
31. For simplicity we divided the 155-km-wide metropolitan region into western, central, and eastern segments. We then used a weighted average of these rates to determine an average shortening rate across the region of 8.5 mm year^{-1}. In the west, geodetic data across the Ventura basin reveal extremely rapid north-south shortening of approximately 8.5 ± 1 mm year^{-1} (63). This rate does not include the Santa Monica Mountains fault system. A. Donnellan *et al.* [*J. Geophys. Res.* **98**, 21727 (1993)] reported a 1 ± 2 mm year^{-1} shortening rate between Oat Mountain along the southern edge of the Ventura basin and Castro Peak in the western Santa Monica Mountains. Although this rate does not account for all shortening across the Santa Monica Mountains system, the geographic position of Castro Peak above the upper part of the Santa Monica Mountains blind thrust ramp indicates that the rate probably includes part of the motion. Measurements from Mount Pinos just south of the San Andreas fault to Castro Peak yield an overall shortening rate across the region of 11 ± 2 mm year^{-1} (63). On the basis of these data we used an average shortening rate for the western region of 10 mm year^{-1}. The shortening rate across the central Los Angeles region is provided by geodetic measurements across the Los Angeles basin from the Jet Propulsion Laboratory (JPL) in Pasadena to the Palos Verdes Peninsula (PV). There is some debate about the shortening rate, with estimates ranging from 5 mm year^{-1} (64) to 7.9 mm year^{-1} [K. Hudnut *et al.*, *Seismol. Res. Lett.* **65**, 59 (abstr.) (1994)]. These rates probably slightly underestimate shortening within the metropolitan region because the measurements only include part of the region of elastic strain accumulation associated with the faults we used in our scenarios: JPL is located in the middle of the Sierra Madre fault zone and the PV site is adjacent to the Palos Verdes fault. An overall Transverse Ranges shortening rate of 13 ± 2 mm year^{-1} (calculated with the San Andreas fault component removed) determined from north of the San Andreas fault near Bakersfield to Santa Catalina Island south of PV (64) indicates significant shortening on faults outside the metropolitan area. For the central part of the region we used a shortening rate of 10 mm year^{-1}. In the east the only fault included in our study area is the Sierra Madre–Cucamonga system, for which we used a geologically defined slip rate of 4.5 to 5.5 mm year^{-1} on the Cucamonga fault, which dips approximately 50° (14). Converting this slip rate into a shortening rate yields 2.9 to 3.5 mm year^{-1}. The Cucamonga fault is 35 km long (14). A shortening rate of 10 mm year^{-1} for the remaining 120-km length of the area results in an overall shortening rate across the metropolitan region of approximately 8.5 mm year^{-1}.

41. Our regression is specific to southern California and uses recent estimates of rupture area and average coseismic slip derived from modeling strong motion, teleseismic, and geodetic data. Because we attempted to model earthquakes within the Los Angeles metropolitan region, we used only earthquakes where the seismogenic crust is likely to be similar. Therefore, we did not use earthquakes from the southern San Jacinto and Salton Trough areas (for example, the 1968 Borrego Mountains, 1987 Elmore Ranch, and 1987 Superstition Hills earthquakes) because heat flow in this region is considerably higher than in the Los Angeles metropolitan area. Consequently, crustal rheology (and presumably earthquake behavior) is probably significantly different than in the Los Angeles metropolitan region, where heat flow is relatively low.
42. T. Hanks and H. Kanamori, *J. Geophys. Res.* **84**, 2348 (1979).
43. Crustal shear rigidity increases markedly downward in the uppermost 5 km of the Earth's crust [see, for example, (37)], leading to different values for earthquakes that rupture to the surface versus earthquakes that rupture only the lower part of the seismogenic zone (that is, >5 km depth). We have taken this into account in using the seismic moment equation to calculate average slip per event for the eight earthquakes that we used for our southern California regressions. For earthquakes that only ruptured below 5 km depth (1987 Whittier Narrows, 1991 Sierra Madre, and 1994 Northridge), we used a value of 3.6 × 10^{11} dyne cm^{-2} whereas for the 1992 Landers earthquake, which ruptured to the surface, we used an overall rigidity of 3.0 × 10^{11} dyne cm^{-2}. For the 1933 Long Beach and 1952 Kern County earthquakes, which ruptured to within a few kilometers of the Earth's surface, we used intermediate values of 3.3 × 10^{11} dyne cm^{-2} and 3.45 × 10^{11} dyne cm^{-2}, respectively. Although one of the two faults that ruptured during the 1971 San Fernando earthquake did rupture the surface, the other fault only ruptured to within about 4 km of the surface (36). We therefore used an intermediate value of 3.3 × 10^{11} dyne cm^{-2} for this earthquake.
44. The base of recent seismicity over much of the metropolitan region is approximately 15 to 16 km (6). However, the 1994 Northridge mainshock originated at 19 km (3), and earthquakes in the northwestern part of the metropolitan area in the Ventura basin extend as deep as 20 to 24 km [A. Bryant and L. Jones, *J. Geophys. Res.* **97**, 437 (1992)], where the base of the brittle upper crust has been bowed down by rapid convergence and sediment loading (22).
45. Slip rates used in this study vary widely in quality. Extensive geologic studies constrain the slip rates for the surficial Whittier, Palos Verdes, Cucamonga, San Cayetano, western Oak Ridge faults, and the Elysian Park and Compton blind thrust faults (7, 14, 17,

21–23, 25). Slip rates on the Santa Monica Mountains thrust fault and the eastern Oak Ridge system are based on balanced section modeling assuming late Pliocene fault initiation (5, 15). Slip rates for some other faults (Sierra Madre fault and southern Newport-Inglewood fault zone) have been extrapolated along the strike from well-determined slip rates determined elsewhere on those fault systems [(14), T. Rockwell *et al.*, in *Environmental Perils, San Diego Region*, P. Abbott and W. Elliott, Eds. (San Diego Association of Geologists, San Diego, CA, 1991), pp. 37–46; S. Lindvall and T. Rockwell, in preparation]. We used the range of geological maximum and minimum slip rates for the Santa Susana fault (G. Huftile and R. Yeats, unpublished data). The Raymond fault slip rate was calculated by assuming that the known recurrence interval (4500 years) (13) records M_w 6.7 events that rupture the entire fault with 1.7 m of slip in each event (Table 2). Forty-seven meters of uplift of the 125,000 oxygen isotope stage 5e marine terrace along the Santa Monica fault (SMF; L. McGill, *U.S. Geol. Surv. Misc. Invest. Ser. Map I-1822* (1989)) indicates a dip-slip rate of approximately 0.5 mm year^{-1}. The SMF, however, exhibits a significant, if not predominant, component of strike-slip motion (J. Dolan *et al.*, *Eos* 73, 589 (abstr., 1992)). Therefore, we assumed a conservative overall slip rate of 1 to 1.5 mm year^{-1}. We extrapolated this rate to the adjacent Hollywood and Malibu Coast faults, for which slip rates are not available. Slip rates for the Clamshell-Sawpit and San Jose faults are unknown. We assumed 0.5 mm year^{-1} to be a reasonable slip rate for these faults on the basis of their geomorphic expression and the recent occurrence of moderate earthquakes on these faults (1988 and 1990 Upland and 1991 Sierra Madre) (38, 39, 65).

45. We used M_w 6.7 earthquakes as a convenient size for an average moderate earthquake because the Los Angeles area has recently experienced two such earthquakes, the 1971 San Fernando and 1994 Northridge earthquakes, which were nearly identical in size (Table 1) (36, 40). There are several additional reasons for using earthquakes of this size. The level of damage caused by these earthquakes is well understood, making M_w 6.7 a useful size for planning purposes. Furthermore, residents of the Los Angeles region know what these earthquakes felt like and will readily be able to understand such a scenario. Finally, M_w 6.7 is approximately the smallest sized earthquake that we can reasonably propose to accommodate all seismically released strain; a scenario based on smaller events (for example, M_w 6.0) would result in implausibly short repeat times.

47. The role of "geologically reasonable" segment boundaries in controlling the ultimate size of an earthquake rupture is very poorly understood, but these boundaries represent a useful starting point for our models. For surficial faults we defined segment boundaries on the basis of pronounced breaks in surficial fault traces, intersections with other active faults, and edges of historical earthquake ruptures. For blind thrust faults we used lateral ramps defined by discontinuities in overlying fold trends (9) and major along-strike changes in geomorphology above blind thrust fault ramps.

48. We cannot rule out the possibility that even larger earthquakes could occur within the metropolitan region. For example, if the Sierra Madre–Cucamonga fault system ruptured together with the Santa Susana and San Cayetano faults, they would produce a M_w 7.64 earthquake. Similarly, the Sierra Madre–Cucamonga system could conceivably rupture coseismically with the San Andreas fault in a *M* 8 earthquake. However, these scenarios require rupture of multiple large fault systems, which, though possible, we consider unlikely.

49. The variability of slip directions on different faults within these strain-partitioned systems precludes simply adding the areas of the faults to calculate the overall moment magnitude of a systemwide earthquake. Rather, we calculated the moment magnitude of subevents occurring on faults that exhibit similar slip directions. For example, we calculated moment magnitudes for two different subevents on the Santa Monica Mountains system: one on the blind thrust ramp and one on the HF-SMF-MCF strike-slip fault system. We then added these to obtain the overall moment magnitude of the systemwide earthquake (M_w 7.5). The variability in coseismic slip direction on the different faults also prevents us from calculating the overall average coseismic slip. Furthermore, because the multiple faults exhibit differing slip rates, we cannot calculate a simple overall average slip rate across the entire system. Consequently, we cannot calculate a recurrence interval for systemwide earthquakes on the Santa Monica Mountains and Los Angeles basin systems.

50. Coseismic rupture of both strike-slip and thrust faults has been observed in a number of large earthquakes worldwide (for example, 1932 Chang Ma, China, M 7.6; 1957 Gobi-Altai, Mongolia, M_s 8.0; 1967 Mogod, Mongolia, M 7.8; and 1988 Spitak, Armenia, M 6.9).

51. We used seven large earthquakes on the six sources because both the blind thrust and strike-slip subsystems of the Santa Monica Mountains system are capable of producing earthquakes of $M_w \geq 7.2$. For the Los Angeles basin system we used an earthquake that ruptures only the blind thrust faults.

54. S. Hough, *Science* **267**, 211 (1994).

55. Two lines of reasoning indicate to us that no aseismic fault creep is occurring along blind thrusts in the region. (i) Because slip on surficial faults is generally concentrated along discrete zones only a few centimeters to a few meters wide, evidence for fault creep in the form of broken roads, sidewalks, pipelines, and oil wells would be obvious, even with relatively slow slip rates. Recent research of growth strata has shown that near-surface deformation above blind thrust faults is similarly discrete, generally encompassing zones less than 10 to 20 m wide (7). Thus, as with surficial faults, fault creep along blind thrust faults would leave obvious traces in any structures built atop an active fold axial surface. No such deformation has been observed. (ii) Blind thrust ramps in the metropolitan region are not slipping aseismically. The term aseismic fault slip is somewhat of a misnomer, as the fault is not actually slipping without causing earthquakes. Rather, slip along such faults is accommodated by minute motions during many thousands of microearthquakes. Creeping faults are only aseismic with respect to moderate and large earthquakes. The creeping segment of the San Andreas fault in central California is a good example. During historic time this section of the fault has not produced any large earthquakes, but it is characterized by the occurrence of thousands of small earthquakes [D. Hill *et al.*, *U.S. Geol. Surv. Prof. Pap.* 1515, 115 (1990)]. The greater Los Angeles metropolitan area is one of the most densely instrumented regions in the world, and microearthquakes $M < 2.0$ are routinely recorded and located by the Southern California Seismographic Network. If any of the blind thrust faults were creeping aseismically, then we would expect them to be highlighted by clouds of thousands of microearthquakes. In fact, Los Angeles area blind thrust ramps are characterized by an almost total absence of microearthquakes, below even the background level in the area. This absence of microseismicity suggests to us that thrust ramps are locked and accumulating strain. Furthermore, all evidence that we have about the relation between maximum faulting depth and the base of seismicity determined from microearthquake studies indicates that earthquakes in the Los Angeles region either rupture down to the base of microseismicity or extend even deeper than the maximum depth of microseismicity. For example, before the Northridge earthquake, most researchers in the region would have predicted the expected maximum depth of earthquake rupture at the base of microseismicity, or about 15 to 16 km (44); The Northridge earthquake, however, ruptured to 20 km depth (3).

SCEC contribution #119.

quake research. For conventional fixed-base buildings, design practice has advanced incrementally as earthquakes occur and lessons are learned. The weakness in this approach is that we have yet to learn the lessons from a very large ($M_w > 7$) earthquake directly beneath an urban area. This is particularly true for tall buildings that are vulnerable to large ground displacements, both for damage and possible collapse.

Designs of base-isolated buildings are based on site-specific ground motions that should account for near-source effects. However, the ground motions presented here are large compared to those currently used for design at sites close to major California faults, and the strongest of our ground motions require exceptional measures for the isolation system to maintain functionality of the building. The practicality of such a goal in the near-source region of a $M_w \geq 7.0$ earthquake is uncertain. Although the focus of this paper is modern buildings, an even greater hazard lies in structures built before modern codes, especially unreinforced or nominally retrofitted brick buildings and nonductile concrete buildings.

REFERENCES AND NOTES

1. M_w is energy magnitude [H. Kanamori, *Tectonophysics* 49, 207 (1978)], and it is similar to the moment magnitude scale [T. Hanks and H. Kanamori, *J. Geophys. Res.* 84, 2348 (1979)]. In the range of 6.5 to 7.5, energy magnitudes are also similar to magnitudes as measured on the surface-wave magnitude scale M_S which, in this magnitude range, has often been called the "Richter scale."

Earthquakes in the Los Angeles Metropolitan Region: A Possible Fractal Distribution of Rupture Size

S. E. Hough

Although there is debate on the maximum size of earthquake that is possible on any of several known fault systems in the greater Los Angeles metropolitan region, it is reasonable to assume that the distribution of earthquakes will follow a fractal distribution of rupture areas. For this assumption and an overall slip-rate for the region of approximately 1 centimeter per year, roughly one magnitude 7.4 to 7.5 event is expected to occur every 245 to 325 years. A model in which the earthquake distribution is fractal predicts that, additionally, there should be approximately six events in the range of magnitude 6.6 in this same span of time, a higher rate than has occurred in the historic record.

In recent years, geologic and geodetic investigations have made possible the evaluation of the earthquake potential for the greater Los Angeles metropolitan region, an area of about 160 km by 100 km (*1*, *2*). By evaluating available geologic and geodetic data for the total region, Dolan *et al.* (*1*) argue that 0.9 to 1.2 cm/year of slip will occur over the distribution of known and unknown faults in the region.

A report by the scientists of the Southern California Earthquake Center (SCEC) has shown that the long-term geodetic deformation rate cannot be accounted for by a continuation of the historic seismic record and has proposed three alternatives: (i) that significant aseismic slip occurs; (ii) that moderate earthquakes [that is, around magnitude (M) 6] must occur significantly more frequently than they did during the historic record; or (iii) that infrequent very large events will occur (*3*).

United States Geological Survey, Pasadena, CA 91106, USA.

In general, it is difficult to determine a priori whether a given fault system will rupture all at once, as occurred during the M 7.3 Landers earthquake in 1992 (*4*), or in isolated segments, as in 1994 during the M 6.7 Northridge earthquake (*5*). In the evaluation of seismic hazard, the distribution of expected earthquakes is critical. It is reasonable to conjecture that the long-term distribution of earthquake rupture areas will be fractal. Studies have shown that the distribution of segmentation of known fault lengths is fractal (*6*) and that the well-known log-normal distribution of earthquake magnitudes is also essentially consistent with this hypothesis (*7*). Although it has been proposed that individual fault segments will not produce a fractal distribution of events (*8*), it is commonly assumed that earthquake release in a region with numerous faults will occur by events with a log-normal distribution of magnitudes, with a maximum event size imposed for each region (*9*).

Dolan *et al.* (*1*) have focused on interpretation of an earthquake budget derived from a synthesis of geologic slip rate data estimated in recent years for Los Angeles area faults. They show that the geologic and geodetic results are generally consistent and contrast two "end-member" scenarios to make up their established earthquake budget: one in which all strain is released by moderate (~*M* 6.7) events, and one in which all moment release occurs during large earthquakes (roughly M 7.2 to 7.6). In this paper, we present a hybrid model similar to that used in the SCEC studies (*8*), allowing a fractal distribution of rupture sizes. We focus on determining the expected rate of moderate and large earthquakes in the greater Los Angeles metropolitan region given the known activity over the historical period, the best available compilation of geologic data, and the most plausible model for the distribution of earthquake rupture.

We first consider the expected rate of seismic moment accrual across the Southern California region, starting with the equation for seismic moment

$$M_o = \mu A d \qquad (1)$$

where μ is the rigidity, A is the rupture area, and d is the slip. For a rectangular fault, $A = WL$, where W is the fault width and L is the fault length. If slip of 0.9 to 1.2 cm/year occurs over a region 160 km wide down to an average seismogenic depth of 17.5 km, the total moment accrual rate dM_o/dt is 7.6×10^{24} to 10.1×10^{24} dyne·cm/year, for a nominal crustal rigidity.

Dolan *et al.* (*1*) showed that recent moderate to large earthquakes located off of the San Andreas fault are well fit by the relation

$$M_w = 4.56 + 0.86\log(A) \qquad (2)$$

where A is in square kilometers and M_w is the moment magnitude, related to seismic moment (*10*) by

$$\log M_o = 1.5M_w + 16.1 \qquad (3)$$

Equation 2 can be combined with the log-normal distribution of seismicity

$$\log N_c = a - bM \qquad (4)$$

to constrain the fractal distribution of rupture areas; N_c is the cumulative number of events with magnitude above M, and a and b are constants (b is the seismic "b-value"). Using M_w as the magnitude in Eq. 4 and assuming a b-value of 1, we find

$$\log N_A = c - 0.86\log(A) \qquad (5)$$

where N_A is the cumulative number of events above area A and c is a constant.

To illustrate how a fractal distribution will fill out a given earthquake budget, we consider a discrete distribution of events. For every occurrence of an earthquake with the maximum rupture area, the coefficient of 0.86 in Eq. 5 predicts that there will be 6.2 events with 1/10 the maximum area [that is, $(10^{0.86} - 1)$], 46 events with 1/100 the area, and so forth.

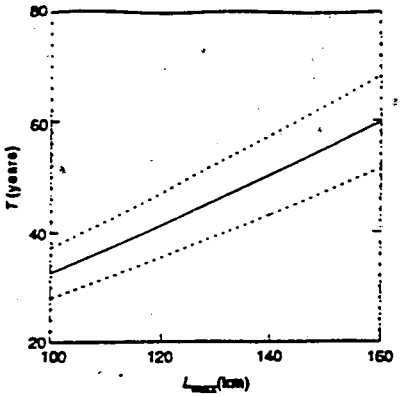

Fig. 1. Average repeat time for moderate events as a function of maximum rupture length L_{max}. Dashed lines indicate results corresponding to an overall slip rate range of 0.9 to 1.2 cm/year; solid line corresponds to the average value. The sizes of the moderate events range from *M* 6.49 for L_{max} = 100 km to *M* 6.67 for L_{max} = 160 km.

If we define $M_{w,1}$ to be the moment of the largest event expected in the region, $M_{w,2}$ to be the moment of the event with a rupture length 1/10 that of $M_{w,1}$, and so forth, the total seismic moment is

$$M_{w,total} = M_{w,1} + 6.2M_{w,2} + 46M_{w,3} + \ldots \qquad (6)$$

To evaluate the relative contributions of the terms of Eq. 6, we must determine how M_w scales with rupture area. For a model with constant stress drop and circular rupture, moment is predicted to scale as radius cubed. For earthquakes that rupture the width of the seismogenic zone, previously determined scaling relations predict that M_w depends on L^2 (*11*).

Combining Eqs. 2 and 3, we obtain a direct empirical relation between moment and area for Southern California earthquakes: $\log M_o = 1.29\log(A) + 22.94$. We thus predict that moment will decrease by a factor of about 20, corresponding to a factor of 10 decrease in rupture area. Because Eq. 2 is generally appropriate for $M_w > 6.0$ and because progressively smaller moments will decrease significantly faster with decreasing rupture size, we consider only the first two terms in Eq. 6. Estimating $M_{w,2}/M_{w,1}$ from Eqs. 2 and 3, we find

$$M_{w,total} = 1.32M_{w,1} \qquad (7)$$

That is, a fractal distribution of rupture lengths implies that most of the total moment release will have to occur in the largest events.

If we define time T_m to be the repeat time of $M_{w,1}$

$$T_m = \frac{1.32M_{w,1}}{(dM_o/dt)} \qquad (8)$$

where dM_o/dt is the moment accrual rate determined above and $M_{w,1}$ is controlled primarily by L_{max}. From Eq. 8 and a given $M_{w,1}$, we can estimate a range of T_m values corresponding to the estimated range of dM_o/dt. We can thus estimate a long-term average estimate of T_m, although it is important to note that periodicity of large events is neither implied nor required by our model.

If L_{max} is assumed to be 100 km, Eqs. 1 to 7 indicate that the maximum moment magnitude $M_{w,1}$ is 7.35, occurring on average every 174 to 231 years (the range in values reflects the overall slip rate range of 0.9 to 1.2 cm/year). The average T_m is 203 years. Unless the historic record for the region is significantly nonrepresentative of the long-term rate, this range of repeat times (and the corresponding rate of moderate-sized events, discussed below) is implausibly low. With our model, one of the few ways that T_m can increase is to allow a longer L_{max}. Assuming a value of 130 km (*12*), we obtain a maximum $M_{w,1}$ of 7.45, with T_m = 245 to 325 years and an average of 284 years.

For the assumed fractal distribution, we predict that for every occurrence of $M_{w,1}$, there will be 6.2 events with rupture areas 1/10 as big. By Eq. 2, and for L_{max} of 130 km, this corresponds to about six events with M 6.6 in the time T_m, yielding an average repeat time of 46 years. For L_{max} = 100 km, we find an average repeat time of 33 years for M 6.5 events, again somewhat implausible considering the historic record. In Fig. 1, we present the average repeat time for moderate events (M 6.5 to 6.7) as a function of L_{max}. An additional consideration, however, is that aftershock distributions are also characterized by log-normal distributions; perhaps 10 to 15% of the smaller events could thus be taken up by aftershocks of the largest events.

If L_{max} is 160 km, $M_{w,1}$ is 7.53 and the average repeat time is 372 years. The average repeat time of M_w = 6.7 events is then 60 years. This is a plausible but not our preferred model because it requires a rupture length comparable to the entire dimension of the Los Angeles region.

The analysis presented here is very simple; in reality, a continuous range of earthquake magnitudes is expected in a fractal distribution. However, our calculations illustrate the fundamental results of combining the total earthquake budget for the greater Los Angeles region with a physically plausible earthquake distribution. Most of the moment release is expected to be taken up by infrequent but extremely large events. Moderate events, with magnitudes similar to that of the recent (17 January 1994)

Northridge earthquake, are also expected, with an average repeat time of 40 to 52 years. The historic record of M 6.5 to 6.7 events in the Los Angeles Basin is still under the long-term predicted rate, even allowing for occasional large events.

Uncertainty in our results stems from three primary factors: the overall slip rate for the region, the maximum rupture size, and the effective fractal dimension implied by our choice of *b*-value and scaling coefficient in Eq. 2. (We do not consider the prima facie assumption of a fractal distribution to be at issue.) The first source of uncertainty is accounted for directly: Our results correspond to the range of slip rates determined from geologic and geodetic compilations (*1*, *2*). The second factor is also addressed: Maximum rupture lengths shorter than 100 km are discounted because of the unrealistically frequent rate of moderate events that is implied. We do not consider the third factor to be significant because of the nature of fractal distributions and earthquake scaling relations: A scaling constant of 1 instead of 0.86 (that is, a strictly self-similar distribution of rupture areas) in Eq. 2 would change Eq. 6 to $M_{o,total} = 1.45M_{o,1}$. This change would increase T_m by about 9% and increase the number of moderate events (M_w 6.6) from about six to nine.

Our calculations are independent of the known details of faulting and slip rates on individual faults in the region, as summarized by Dolan *et al.* (*1*). Their results can be compared to ours: The six multiple-fault-segment scenarios yield events with M_w 7.20 to 7.58, produced, on average, every 140 years. This value is about half of our preferred estimate but is not inconsistent with our results because 70 to 80% of the geologically determined scenario earthquakes have M_w = 7.2 to 7.3 (*14*). Also, the fractal analysis permits a fraction of the moment rate, approximately 30%, to be accounted for by moderate events.

11. Given Eq. 1 and the empirical scaling relation $\sigma = \nu L$ for a rectangular fault (*13*), M_o is expected to scale as WL^2. For crustal earthquakes, W will be bounded by the width of the brittle seismogenic zone; for large earthquakes, M_o is thus expected to scale as L^2.
12. Our calculations are for a seismogenic depth of 17.5 km; if we allow for dipping faults with greater down-dip width, one could obtain the same area and moment with a shorter fault (*7*).
13. C. H. Scholz *et al.*, *Bull. Seismol. Soc. Am.* 76, 68 (1986).
14. With the use of Eq. 3, a difference of 0.2 in M_w (between 7.25 and 7.45) implies a difference in seismic moment of a factor of 2. From Eq. 1, the implied difference in area is 1.7. A difference of 0.2 in M_w is thus nontrivial, and the shorter repeat time of these events dominates the average in the calculations by Dolan *et al.* (*1*) (the 70 to 80% range reflects the uncertainty in whether the Santa Monica mountains system will rupture as a whole or in subsystems).

Rapid Accretion and Early Differentiation of Mars Indicated by $^{142}Nd/^{144}Nd$ in SNC Meteorites

Charles L. Harper Jr.,* Laurence E. Nyquist, Brij Bansal, Henry Wiesmann, Chi-Yu Shih

Small differences in the ratio of neodymium-142 to neodymium-144 in early formed mantle reservoirs in planetary bodies are the result of in situ decay of the extinct radionuclide samarium-146 and can be used to constrain early planetary differentiation and therefore the time scale of planetary accretion. The martian meteorite Nakhla (~1.3 billion years old), the type sample of the nakhlite subgroup of the Shergottite-Nakhlite-Chassigny (SNC) meteorites, exhibits a 59 ± 13 parts per million excess in the ratio of neodymium-142 to neodymium-144 relative to normal neodymium. This anomaly records differentiation in the martian mantle before 4539 million years ago and implies that Mars experienced no giant impacts at any time later than 27 million years after the origin of the solar system.

Planets in the inner solar system are widely believed to have accreted from an initial swarm of planetesimals by hierarchical coagulation, which involves the merging of objects of increasing size until only a small number of large objects remain in each radial zone (*1*). According to this view, the late stages of planetary accretion are dominated by a few giant impacts. The spins of both Earth and Mars are consistent with one or more of these events during accretion (*2*). Giant impacts generate transient, mantle-wide magma oceans, and therefore the histories of the terrestrial planets are expected to have begun with an epoch of giant impacts and magma oceans. However, the durations for these accretionary epochs are unknown. Estimates from planetesimal coagulation models are generically uncertain at late times and fundamental issues remain unresolved, so isotopic age determinations are needed to constrain accretion and giant impact time scales directly.

The presence of a small but significant abundance of ^{146}Sm (which decays by α emission to ^{142}Nd with a half-life of 103 million years) in the early solar system provides a means for dating early episodes of differentiation in planetary bodies based on the preservation of isotopic signatures at depth in mantle reservoirs (*3*). The ^{146}Sm-^{142}Nd system is ideal for dating differentiation episodes in the silicate portions of planets because other large-scale cosmochemical processes such as volatile depletion or core formation do not fractionate Sm/Nd and because this system can be linked to the long-lived ^{147}Sm-^{143}Nd system. Because the initial solar system abundance of ^{146}Sm was small [$^{146}Sm/^{144}Sm$ = 0.0080 ± 0.0010 at 4566 million years ago (Ma) (*4*)] and the range of Sm/Nd fractionation in large-scale reservoirs is limited, $^{142}Nd/^{144}Nd$ shifts resulting from ^{146}Sm decay are generally expected to be less than one part in 10^4 (= 1 ε-unit). Use of the ^{146}Sm-^{142}Nd systematics therefore requires accurate determination of $^{142}Nd/^{144}Nd$ shifts at a resolution of better than 20 ppm (±0.2 ε-unit) relative to a reference standard. We report well-resolved ^{142}Nd shifts in SNC meteorites and outline their significance for the early history of Mars (*5*), which is where these meteorites are thought to have been derived (*6*).

CHAPTER 3

OVERVIEW OF INVESTIGATIONS FOR ASSESSING SEISMIC HAZARDS

Introduction

Investigation of potential seismic hazards at a site can be performed in two steps or stages: (1) a preliminary screening investigation, and (2) a quantitative evaluation of the seismic hazard potential and its consequences. As noted below, it is possible to successfully complete the investigation by skipping one or the other stage. For example, a consultant's screening investigation may find that a previous site-specific investigation, on or adjacent to the project site, has shown that no seismic hazards exist, and that a quantitative evaluation is not necessary. Conversely, a consultant may know from experience that a project site is susceptible to a given hazard, and may opt to forego the screening investigation and start with a quantitative evaluation of the hazard.

Some lead agency reviewers recommend that for large projects the developer's consultant(s) meet with the lead agency technical reviewer prior to the start of the site investigation. This allows the consultant and technical reviewer to discuss the scope of the investigation. Topics of this discussion may include the area to be investigated for various hazards, the acceptability of investigative techniques to be used, on-site inspection requirements, or other local requirements.

Items to Consider in the Site Investigation Study

The following concepts are provided to help focus the site-investigation report:

1. Consultants are encouraged to utilize, if possible, the latest California Department of Conservation, Division of Mines and Geology (DMG) seismic ground-motion parameter data. This information is available in DMG's Seismic Hazard Evaluation Reports. The hazard zone mapping procedure for liquefaction and earthquake-induced landsliding utilizes state-of-the-art probabilistic ground-motion parameters developed jointly by the DMG and the U.S. Geological Survey, and published by the DMG (Petersen and others, 1996).

2. The fact that a site lies within a mapped zone of required investigation does not necessarily indicate that a hazard requiring mitigation is present. Instead, it indicates that regional (that is, not site-specific) information suggests that the probability of a hazard requiring mitigation is great enough to warrant a site-specific investigation. However, the

Engineering Observations on Ground Motion at the Van Norman Complex after the 1994 Northridge Earthquake

by J. P. Bardet and C. Davis

Abstract During the 1994 Northridge earthquake, the Van Norman Complex yielded an unprecedented number of recordings with high acceleration, in the close proximity of the fault rupture. These strong-motion recordings exhibited the pulses of the main event. One station recorded the largest velocity ever instrumentally recorded (177 cm/sec), resulting from a 0.86 *g* peak acceleration with a low frequency. Throughout the complex, the horizontal accelerations reached peak values ranging from 0.56 to 1.0 *g*, except for the complex center, where the peak acceleration did not exceed 0.43 *g*. The vertical acceleration reached maximum peak values comparable with those of the horizontal acceleration. The acceleration response spectra in the longitudinal and transverse directions were significantly different. Such a difference, which is not yet well documented in the field of geotechnical earthquake engineering, indicates that the amplitude and frequency content of the ground motion was directionally dependent in the Van Norman Complex.

Introduction

The Van Norman Complex (VNC) is an engineering facility that supplies a large and critical amount of water and power to the city of Los Angeles. In the past 23 years, the VNC was shaken by two moderate M_w 6.7 earthquakes. On 9 February 1971, it was struck by the San Fernando earthquake, which originated on the San Fernando Fault, 11 km northeast of the complex (USGS/SCEC, 1994). Although the ground motions in 1971 were only partially recorded (Scott, 1973), the VNC provided geotechnical engineers with one of the first well-documented cases of near-field dynamic response of two earth dams—the Upper and Lower San Fernando Dams. On 17 January 1994, the VNC was again shaken by the Northridge earthquake, which occurred on a previously unknown blind thrust fault, 11 km southwest of the complex (USGS/SCEC, 1994). Since 1971, the VNC has been instrumented with strong-motion accelerographs, in view of its numerous critical facilities close to active faults. In 1994, these instruments provided us with a unique set of strong-motion recordings with maximum peak accelerations reaching 1 *g*.

This article reports on the strong-motion recordings at the VNC after the 1994 Northridge earthquake and discusses their relevance from a geotechnical engineering point of view. This study is part of a research program that aims at understanding the ground displacements observed in the complex after the 1994 Northridge earthquake. The measured effects of these strong motions on the VNC geotechnical structures are described not in this article but in the articles of Bardet and Davis (1995a, 1995b) and Davis and Bardet (1994, 1995a, 1995b, 1995c).

The Van Norman Complex

The VNC is one of the most important sites owned and operated by the Los Angeles Department of Water and Power (LADWP). As shown in Figure 1, it is located in the northern San Fernando Valley along Interstate 5 between the 405 and 210 interchanges, approximately 11 km north of the 17 January 1994 Northridge earthquake epicenter. The VNC serves as a terminal for the First and Second Los Angeles Aqueducts. It receives, treats, stores, and distributes 80% of the annual water supply for the city of Los Angeles. Figure 2 shows the location of important geotechnical structures within the VNC, which include the Los Angeles Reservoir with the Los Angeles Dam and the North Dike, the LAA Filtration Plant, the Van Norman Bypass Reservoir, the Upper and Lower San Fernando Dams, the Backwash Reclamation ponds, several debris basins with their retaining dams, and finally, major pipelines and trunklines. The VNC also encompasses major power facilities, such as the Rinaldi Receiving Station, a critical link in maintaining an adequate power supply for the city of Los Angeles; the Sylmar Converter station; and the San Fernando Power Plant. The Jensen Filtration Plant, which is operated by the Metropolitan Water District (MWD), is located to the northwest of the VNC.

The 1994 Northridge Earthquake

The Northridge earthquake occurred at 4:31 a.m. (Pacific standard time) on 17 January 1994, with a moment magnitude of 6.7 (Trifunac *et al.*, 1994; USGS/SCEC, 1994).

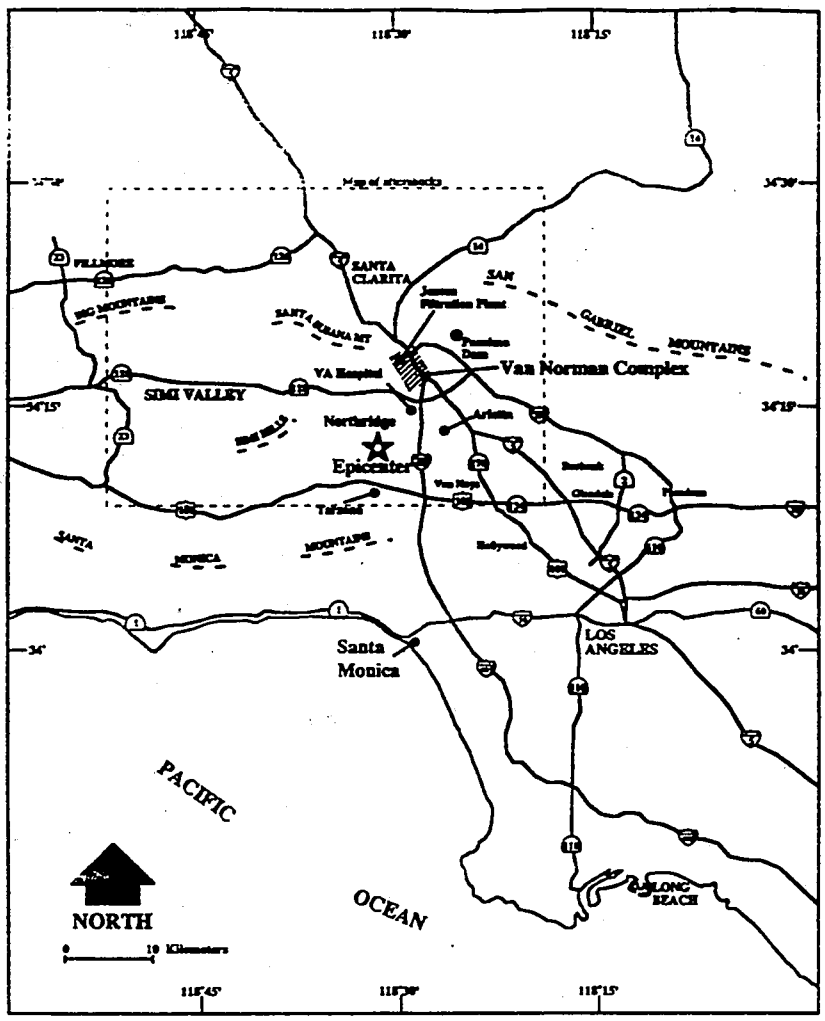

Figure 1. View of Los Angeles area and location of Van Norman Complex.

The main release of energy occurred on a previously unmapped blind thrust fault (USGS/SCEC, 1994), which strikes at approximately 70° N to 80° W and dips to the south under the San Fernando Valley at approximately 35° to 45°. The hypocenter was located at 34.211° N, 118.537° W at a depth of 18.5 km (Wald and Heaton, 1994). It took about 7 sec for the fault to rupture over a 280-km² area, which generated 6 to 10 sec of strong shaking.

Figure 3 shows a plan view of the fault plane, and the epicenters of the mainshock and aftershocks from 17 January through 29 June 1994. During the main event, two distinct subevents, with a possible third subevent, have been identified (Wald and Heaton, 1994; and USGS/SCEC, 1994). The first subevent originated at a depth of 18.5 km, began propagating to the north, then curved to the north-northeast, directly toward the VNC. The rupture during the first subevent ended at approximately a depth of 10 km, nearly underneath the VNC. The second, and longer, subevent began approximately 2 to 3 sec after initiation of the first subevent, and at about 8 km northwest, along strike, from the hypocenter. The rupture during the second event ended at approximately a depth of 7 to 8 km under the Santa Susana Mountains. These two main ruptures had comparable total slip, although the second one produced the largest maximum slip (approximately 3.9 m).

The VNC is located above the fault plane, at its northern boundary, and in line with the northerly direction of fault rupture. The VNC was also struck by many nearby aftershocks. As shown in Figure 3, the aftershocks were densely spaced beneath the VNC. Figure 4 shows the depth distribution of the aftershocks that occurred in the rectangular area along section AA′ of Figure 3, which is centered on the VNC and aligned perpendicular to the strike of the fault plane. The aftershocks occur within a narrow band delineating the 35° to 45° southern dip of the fault plane below a depth of 7 km. The large number of aftershocks beneath the VNC suggests that this area of the fault plane did not fully rupture during the initial energy release. Studies indicate that aftershocks concentrate around the area of large fault slip in regions that are stressed by the mainshock faulting (e.g., Mendoza and Hartzell, 1988). Hereafter, we only report the mainshock and omit the aftershocks.

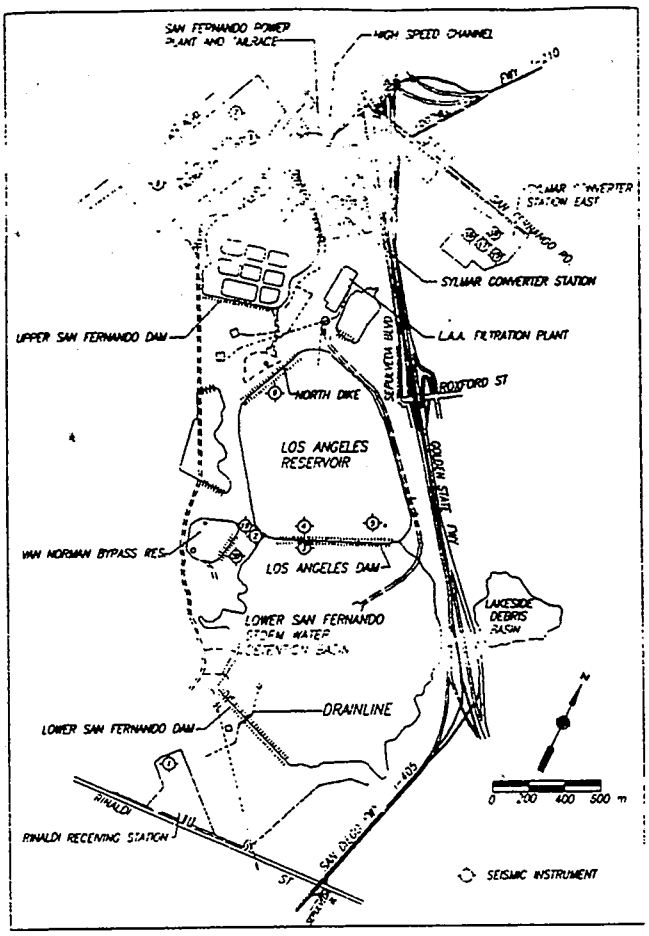

Figure 2. Van Norman Complex, its main structures and location of seismic stations.

Strong-Motion Recordings in the Van Norman Complex

Trifunac *et al.* (1994) estimated that the uncorrected peak ground accelerations reached 1 *g* in a 150-km² area just north of the epicenter and was larger than 0.5 *g* in a 450-km² area about the epicenter. Severe ground motions were also recorded in small isolated areas, 25 km to the south and southeast of the epicenter, due to local site amplification. The Tarzana Station, 6 km south of the epicenter, yielded one of the largest ground accelerations: 1.82 *g* horizontal and 1.18 *g* vertical. However, this particular recording strongly contrasts with that of LADWP, located only 2 km southeast at Encino Reservoir, which recorded 0.22 *g* horizontal and 0.15 *g* vertical.

The Northridge Earthquake produced an unprecedented number of near-source strong-motion recordings from various origins: California Division of Mines and Geology (CDMG), U.S. Geological Survey (USGS), University of Southern California (USC), LADWP (Lindvall Richter Benuska Associates, 1994), and Southern California Edison (Edison). A list of recordings, except for those of LADWP and Edison, can be found in Shakal *et al.* (1994), Porcella *et al.* (1994), and Trifunac *et al.* (1994). Table 1 lists only the recordings that were obtained by LADWP and USGS in the area covered by Figure 2. As shown in Figure 2, the VNC area has a dense array of seismic instruments with 20 recording stations. A total of 19 stations, including 17 accelerographs and 2 seismoscopes, recorded the mainshock. Station 14 failed to function during the mainshock but resumed working during the aftershocks. Of the triggered accelerographs, nine stations recorded free-field responses, five stations structural responses, and three stations embankment dam responses. As shown in Figure 2 and Table 1, free-field peak horizontal accelerations of 0.84, 1.0, and 0.90 *g* were recorded at the south, northwest, and northeast ends of the VNC, respectively. Free-field peak vertical accelerations at the same locations were recorded at 0.85, 0.52, and 0.64 *g*, respectively.

Attenuation of Peak Acceleration with Distance

Figures 5 and 6 show the attenuations of peak ground accelerations, in the VNC and other locations, with epicentral distance. The epicentral distance is defined as the distance separating the epicenter and the recording station. Different symbols are used to distinguish the recordings on alluvium and bedrock and those of the VNC. These geological distinctions were provided by Porcella *et al.* (1994), Trifunac *et al.* (1994), and Boore (1994). The stations with unknown geological conditions are listed as undefined.

The LADWP recordings are all located between 10 and 13 km from the epicenter. There are only five recordings, besides those of LADWP, that are closer to the epicenter. As shown in Figure 5, the attenuation curve of Trifunac *et al.* (1994), which is based on the attenuation relationship of Trifunac (1976), fits the maximum component of peak horizontal accelerations relatively well, although it was conceived to fit both horizontal components. However, this attenuation curve underpredicts horizontal accelerations beyond 40 km from the epicenter. As shown in Figure 6, the attenuation curve of Trifunac *et al.* (1994) also predicts the recorded peak vertical accelerations relatively well in the range 15 to 40 km but underpredicts them outside this range.

The peak accelerations of the VNC vary rapidly (over 3.5 times) over a short distance (2 km). The horizontal accelerations are 0.43 and 0.32 *g*, and the vertical values are 0.32 and 0.13 *g* at stations 2 and 3, respectively. These values contrast sharply with the horizontal values of 0.84 and 1.0 *g*, and the vertical values of 0.85 and 0.79*g* at stations 1 and 7, which are 1 km to the south and 1 km to the north of stations 2 and 3, respectively.

As shown in Figures 5 and 6, the VNC recordings are in agreement with those obtained by CDMG, USGS, and USC and are a useful complement to the existing data set of strong-motion recordings in the near-source region.

Figure 7 compares the maximum peak vertical and horizontal accelerations recorded at the VNC and other locations. As shown in Figure 7, maximum peak vertical accel-

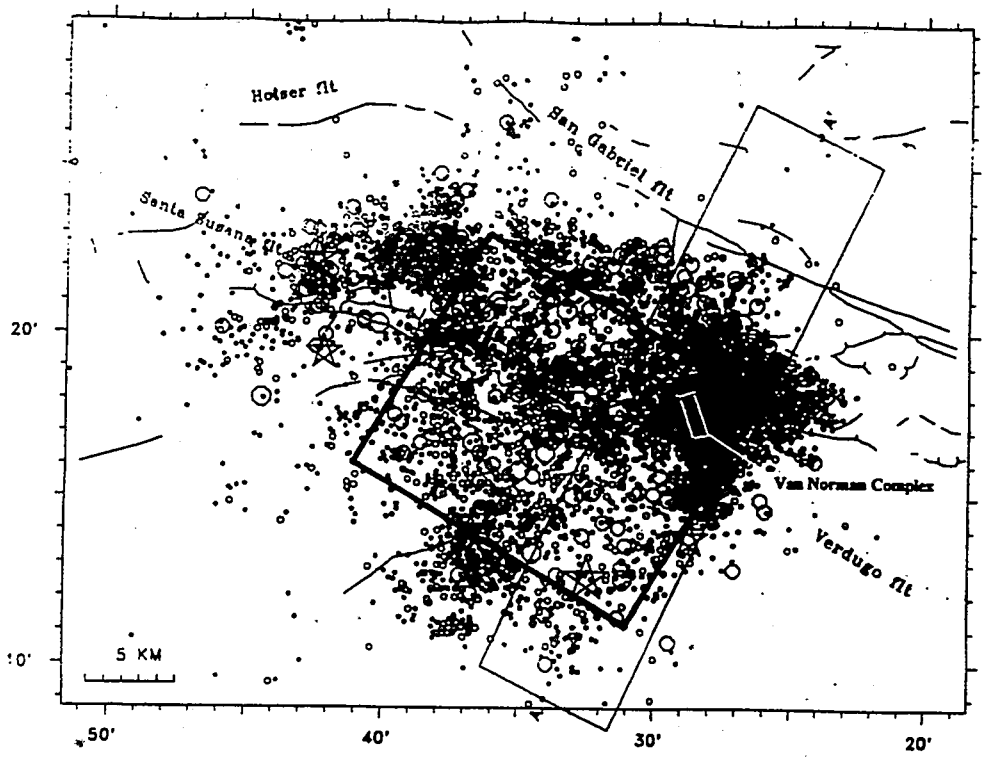

Figure 3. Map of aftershocks from 17 January to 29 June 1994 (after Haukson, 1994). (The bold line rectangle indicates dimensions of fault plane. The symbols are defined in Fig. 4.)

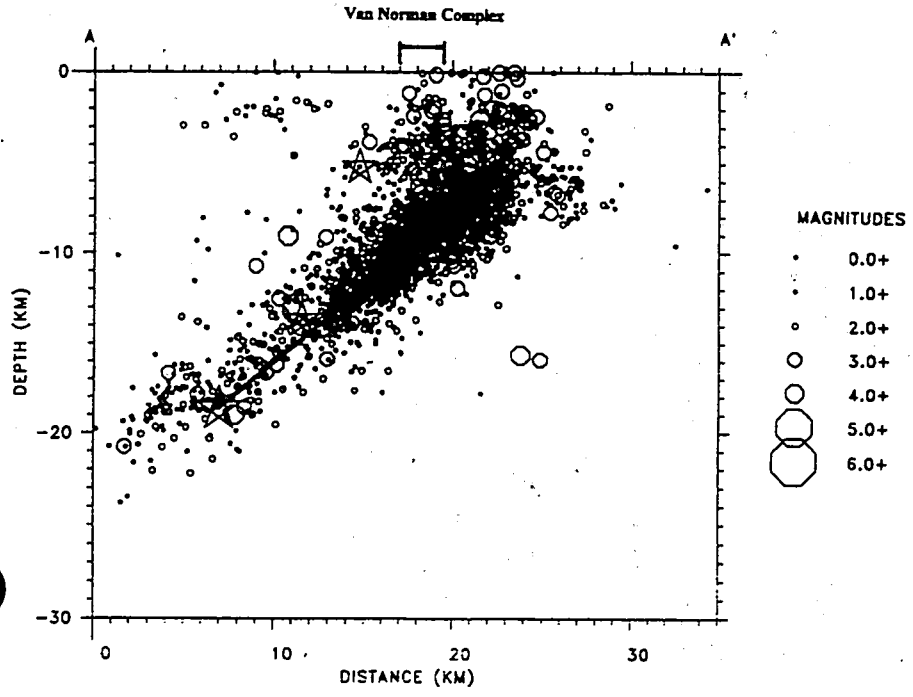

Figure 4. Aftershocks in section AA' Figure 3 (after Haukson, 1994).

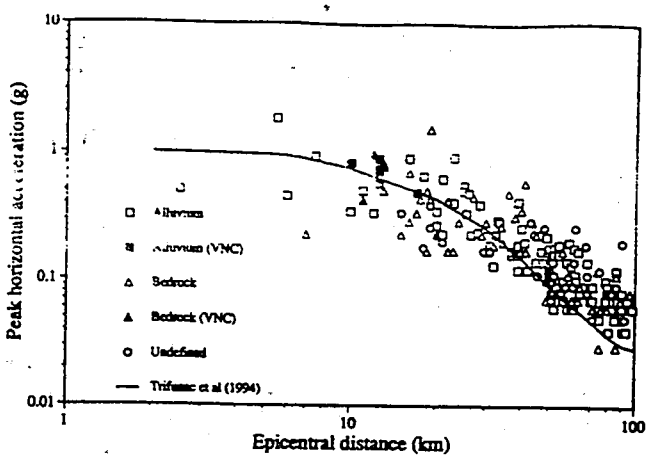

Figure 5. Attenuation of peak horizontal acceleration with epicentral distance.

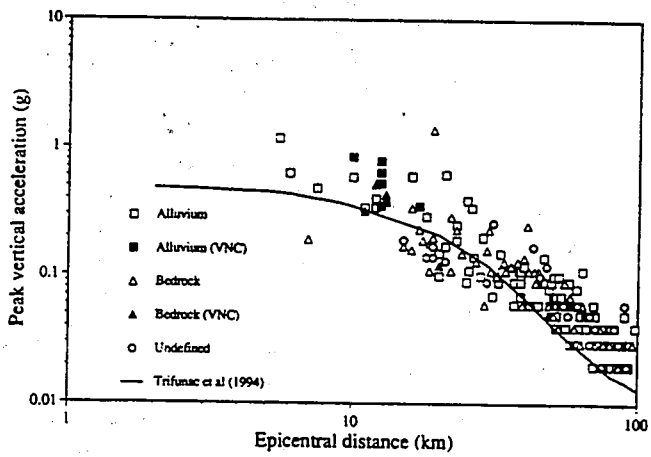

Figure 6. Attenuation of peak vertical acceleration with epicentral distance.

erations exceed 66%, and even 100%, of the maximum peak horizontal acceleration. All but one of the recordings on bedrock fall below the 100% limit. In the VNC, five records exceed the 66% limit, including two records above the 100% limit. These latter recordings are at station 1 on the southern end of the VNC and at station 11 on the northern end of the VNC.

Time Histories and Response Spectra of Strong Motion

Eight out of twenty strong-motion recordings throughout the VNC were selected. The strong-motion recordings were digitized and processed by Lindvall Richter Benuska Assoc. (1994), using standard volume 2 and 3 algorithms by Lee and Trifunac (1979). The baseline and instrument response corrections were performed using an Ormsby filter. The low- and high-frequency filter settings were in the range of 0.05 to 0.1 Hz and 25 to 27 Hz, respectively. The selected recordings are identified by numbers ranging from 1 to 20

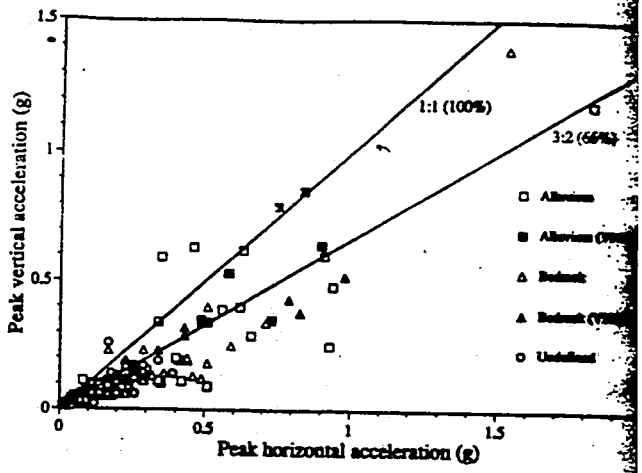

Figure 7. Relation between vertical and horizontal peak accelerations.

in Table 1. As shown in Figure 2, these recordings—located to the south, center, northwest, and northeast of the VNC—are arranged in four groups. The horizontal accelerations which were recorded in different directions depending on the instrument orientation, are projected onto the longitudinal and transverse directions. The longitudinal direction is given by the relative position of the station with respect to the epicenter. The transverse direction is perpendicular to the longitudinal direction. The longitudinal and transverse directions are almost identical for all the instruments (i.e., N33°E and S57°E), due to their close proximity to one another and their distance from the epicenter.

The frequency contents of accelerations will be represented by using normalized acceleration response spectra with 5% damping. The normalized acceleration response spectrum is the acceleration response spectrum divided by the maximum peak acceleration. These response spectra will be compared to design spectra of the NEHRP code for soil profile types 1, 2, and 3 (FEMA, 1992). The NEHRP normalized acceleration spectra increases linearly from value 1 at zero period, reaches a constant value equal to 2.5, then decreases asymptotically toward zero for long periods. As specified by NEHRP, the plateau width depends on the soil profile type. The soil types for NEHRP design spectra are similar to the UBC soil type classifications (ICBO, 1994). Soil profile type 1 (S_1) includes soil profiles "with either: (1) rock of any characteristic, either shale-like or cristalline in nature, that has a shear wave velocity greater than 2,500 feet per second or (2) stiff soil conditions where the soil depth is less than 200 feet and the soil types overlying the rock are stable deposits of sands, gravels, or stiff clays." Soil profile type 2 (S_2) characterizes "a soil profile with deep cohesionless or stiff clay conditions where the soil depth exceeds 200 feet, and the soil types overlying rocks are stable deposits of sands, gravels, or stiff clays." Soil profile type 3 (S_3) encompasses "soil profiles containing 20 to 40 feet in thickness of soft-to-medium stiff clays with or without intervening lay-

ers of sand or other cohesionless soils." Based on the shear-wave velocities and soil depths in Table 2, all the accelerograms of Table 1 are located on soil profile type 1. However, their normalized response spectra will be compared to the NEHRP spectra of soil profile types 1, 2, and 3.

Rinaldi Receiving Station (Station 1)

As shown in Figure 2, station 1 is located in the southern tip of the VNC. As shown in Figure 8, after 2.0 sec, the longitudinal acceleration record contains a large pulse with a period of 1.0 sec. This pulse generates a peak acceleration of 0.86 *g* and represents a large energy release because of its long period and large amplitude. In contrast to most strong-motion recordings during past earthquakes, this particular acceleration record displays a peak with a low frequency instead of a high frequency. After time integration and rotation, the acceleration of Figure 8 generates the largest ever instrumentally measured velocity, 177 cm/sec (Heaton *et al.*, 1995), and a differential displacement exceeding 60 cm. After 5 sec, the first pulse is followed by a second pulse of smaller amplitude but longer period, and then after 8 sec, by a third pulse of even smaller amplitude. These pulses correspond to the three successive subevents of Wald and Heaton (1994) that took place at 2-sec intervals. As shown in Figure 9, the transverse components of acceleration, velocity, and displacement are smaller than their longitudinal counterparts. The maximum transverse velocity (70 cm/sec) is obtained just before the second pulse and corresponds to the maximum amplitude of transverse differential displacement of 40 cm. As shown in Figure 10, the peak value of the vertical acceleration (0.85 *g*) is about the same as the peak longitudinal acceleration. It takes place at the end of the first pulse and generates a vertical velocity of 50 cm/sec and a maximum vertical differential displacement of 19 cm.

Cone penetration tests at the Rinaldi Receiving Station (The Earth Technology Corporation, 1994) indicate that station 1 is underlain by silty sands and sandy silts with lenses of clay and gravel. The upper 7 m have a relative density ranging from 20% to 60% and a standard penetration test (SPT) blow count $(N1)_{60}$ between 3 and 20, with values above 40 in gravel layers. These alluvial deposits from the San Fernando Creek correspond to the shallow alluvium of Table 2, with shear-wave velocity ranging from 200 to 300 m/sec. The Pico Formation bedrock is at about a depth of 10 m and has a shear-wave velocity approximately equal to 1100 m/sec. Ground cracking, but no direct surficial evidence for liquefaction (e.g., sand boils), was observed at this location, which has a water table below 10 m.

Record 1 was obtained from an instrument having slight problems with film advancement. Although the instrument triggered, the film did not advance immediately at the beginning of the strong shaking, and a few seconds of strong ground motions were lost at the beginning of the record. The film stalled after 3 sec of recording for approximately 0.05 sec. This missing 0.05-sec gap was added to the record, after matching the slopes on both sides of the stall. After this correction, the record of Figure 9 is believed to be representative of the actual ground acceleration at the Rinaldi site (Lindval Richter Benuska Associates, 1994). Record 1 is useful to analyze the significant damage to electrical equipment at the Rinaldi Receiving Station and the damage to pipes and the Lower San Fernando Dam at the southern part of the VNC.

Los Angeles Dam (Stations 2 and 3)

As shown in Figure 2, stations 2 and 3 are located at the Los Angeles Dam, at the center of the VNC. As shown in Figures 11 and 12, the two first pulses previously identified from record 1 are clearly observable in records 2 and 3 after 2.5 and 6 sec. The third pulse is also detectable after 9 sec. The second pulse has a 2.5-sec period in the transverse direction at station 2. As shown in Figures 11 through 16, records 2 and 3 are very similar. Recording 3 has a smaller peak acceleration and fewer high-frequency components than recording 2. As shown in Table 1, in contrast to other recordings, records 2 and 3 display small peak accelerations.

Stations 2 and 3 are both located on bedrock. However, station 3 is located under the earth embankment fill while station 2 is on the ground surface. After the poor performance of the Lower and Upper San Fernando Dams during the 1971 San Fernando earthquake, the alluvium was completely removed to expose the bedrock and to lay out the foundation for the Los Angeles Reservoir, which was completed in 1977. The sedimentary bedrock at these two stations consists of the Sunshine Ranch Member of the Saugus Formation (Dibblee, 1991). The Sunshine Ranch Member consists of reddish to greenish claystone, siltstone, and sandstone and interbedded pebble-cobble conglomerate. The Sunshine Ranch Member is the oldest member of the Saugus Formation and is finer-grained than the upper member of the Saugus Formation that is located north of the Los Angeles Dam. The Saugus Formation is generally poorly consolidated and poorly cemented; however, the older Sunshine Ranch Member contains some limy concretions and limestone beds. The Sunshine Ranch Member was deposited during the late Pliocene, in a nonmarine environment above the marine water line, while the near-shore Pico Formation was deposited in shallow brackish water (Saul, 1975). The Sunshine Ranch Member contacts the underlying Pico Formation in areas that were once a coast line. Unfortunately, there is no shear-wave velocity data directly measured beneath stations 2 and 3. However, the shear-wave velocity in this location may be assumed in the order of 1000 m/sec, based on the shear-wave velocities measured in the bedrock of the Upper and Lower San Fernando Dams (see Table 2), respectively, north and south of stations 2 and 3. These high shear-wave velocities were measured by DWR (1971) many years ago, which may warrant new measurements utilizing more modern techniques. The response spectra of both stations 2 and 3 in the transverse direction have peaks broader than those generally encountered for bedrock stations.

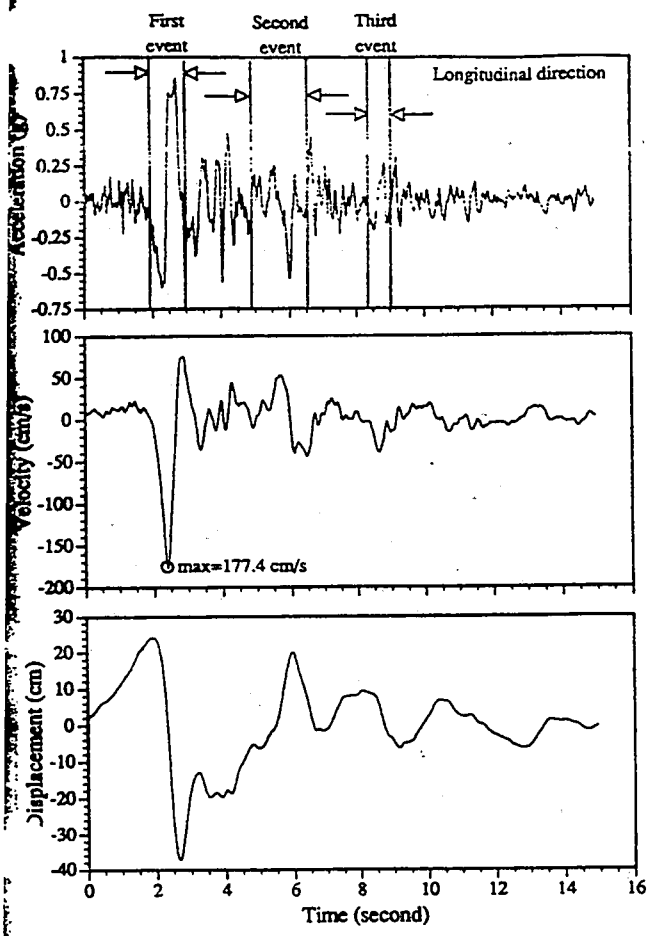

Figure 8. Time history of longitudinal component of acceleration, velocity, and displacement recorded at station 1.

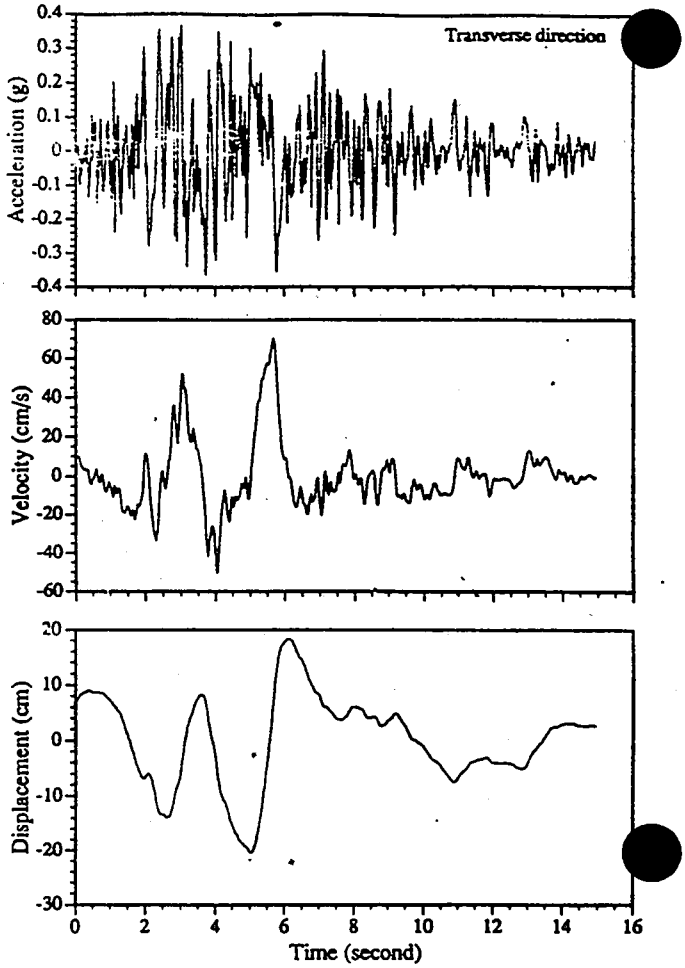

Figure 9. Time history of transverse component of acceleration, velocity, and displacement recorded at station 1.

Sylmar Converter Station (Stations 10, 11, and 13)

There are five recordings at the Sylmar Converter Stations, north of the VNC. As shown in Figure 2, stations 10, 11, and 13 are to the west of Freeway 5, whereas stations 15 and 16 are to the east of Freeway 5. All these stations are located at the same latitude as the MWD Jensen Filtration Plant.

As shown in Figures 11 and 12, the first and second pulses can be identified in records 10, 11, and 13. The first pulse is clearly noticeable after 3 sec in the longitudinal direction but barely noticeable in the transverse direction. The second pulse starts after 5 sec and has a long period of 2.5 sec. The peak accelerations range from 0.55 to 0.67 g in the longitudinal direction and from 0.46 to 0.65 g in the transverse direction. Records 10 and 11 are similar, one being located in the free field and the other on the ground floor of w-rise steel structure.

The converter station is founded over the Grapevine Creek channel, on an alluvium layer approximately 22-m thick, deposited within the Mission Hills syncline. Soil deposits have been classified as silty sand in the upper 3 to 4 m, clayey sand to clayey silt from 4 to 5 m, and silty sand to sandy silt at greater depths. As shown in Table 2, P-wave velocities of 300 m/sec were recorded in the upper 4 m and 1660 m/sec below 4 m (Fallgren and Smith, 1971). These values correspond to shear-wave velocities of about 120 to 150 m/sec and 275 m/sec, respectively, assuming that the larger P-wave velocities were measured below the water table.

The absence of high frequencies in records 10, 11, and 13 can be attributed to the nonlinear response of alluvium, especially to the liquefaction and lateral spreading of the underlying soils, which was independently observed in this region (Davis and Bardet, 1995a). Compared with recordings 10 and 11, recording 13 has no high frequencies, and its peak accelerations occurred during the first pulse, instead of the second pulse. This observation suggests that the alluvium underlying station 13 may have failed during the first pulse and could not transmit the acceleration of the second pulse.

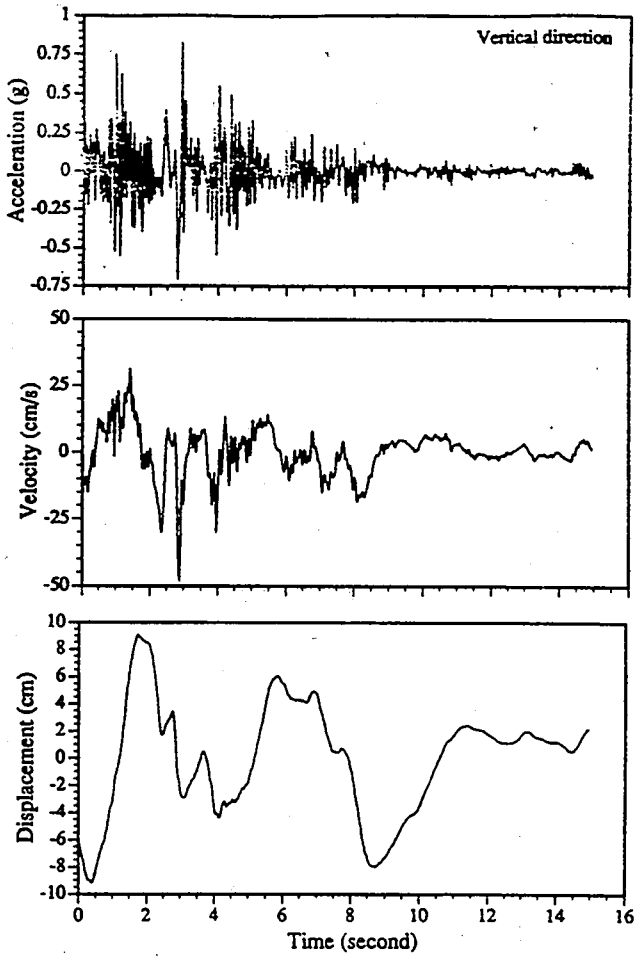

Figure 10. Time history of vertical component of acceleration, velocity, and displacement recorded at station 1.

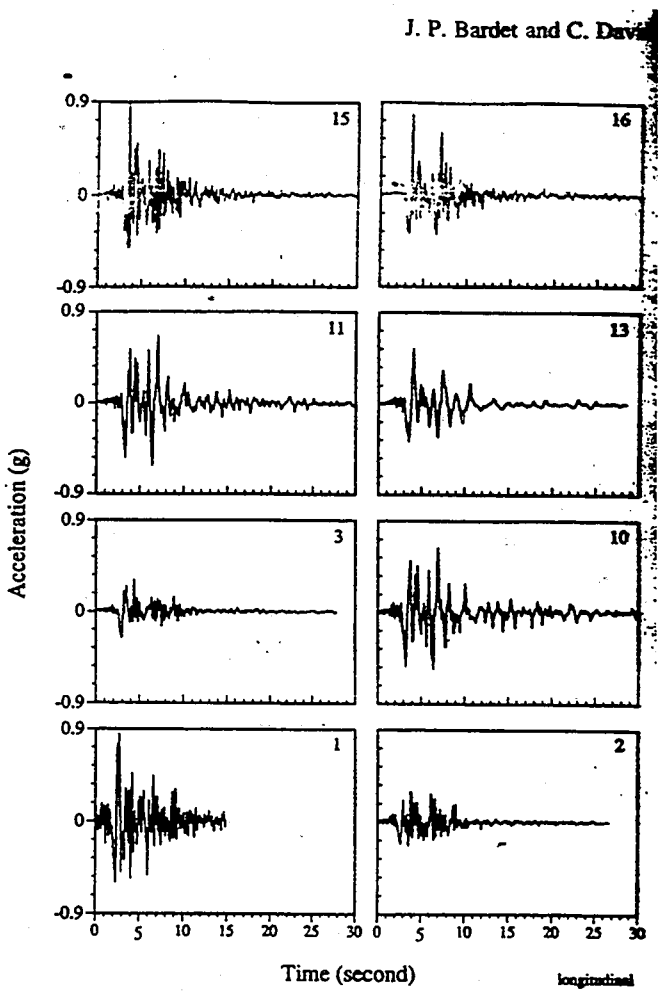

Figure 11. Time history of longitudinal acceleration recorded at eight stations in the Van Norman Complex.

Sylmar Converter Station East (Stations 15 and 16)

Stations 15 and 16 yield recordings similar to those of stations 10, 11, and 13. Station 15 is a free-field station, while station 16 is installed on a hall floor. Like records 10, 11, and 13, the longitudinal and transverse components of records 15 and 16 display the first two pulses previously described. However, these recordings have larger peak accelerations and contain much more high frequencies than those at stations 10, 11, and 13. The peak accelerations are 0.9 and 0.79 *g* in the longitudinal direction and 0.36 and 0.46 *g* in the transverse direction.

Stations 15 and 16 (i.e., stations at Sylmar Converter Station East) are underlain by a thin layer (up to 2 m) of compacted fill over Saugus Formation bedrock. The layer of fill, which is too thin to have a significant effect on site response, is omitted in Table 2. The Saugus Formation is a coarse-grained poorly consolidated and poorly cemented nonmarine sedimentary rock, consisting of light gray pebble-cobble conglomerate, sandstone, siltstone, and greenish to reddish claystone, which was deposited by streams during the early to middle Pleistocene (Saul, 1975). At this site, the Saugus Formation has engineering properties of a stiff to hard soil (The Earth Technology Corporation, 1984). In the low topographic region, the Saugus Formation behaves as highly weathered clay to clayey silt and is nearly indistinguishable from alluvium, while in the higher topographic area to the southeast, it becomes slightly calcified and firmer. As shown in Table 2, shear-wave velocities of 335 to 436 m/sec were recorded in the Saugus Formation near the recording stations.

As previously mentioned, records 15 and 16 have larger peak accelerations and higher-frequency contents than records 10, 11, and 13. This observation is in agreement with field observations. There was no obvious sign of ground failure at these locations.

Comparison of Recordings

Figure 14 shows the simultaneous variation of the East–West and North–South components of the horizontal accelerations at the eight stations previously defined. The longitudinal direction has been defined at an azimuth of 33°. In records 1, 3, 15, and 16, the peak acceleration is larger in the longitudinal direction than in the transverse direction.

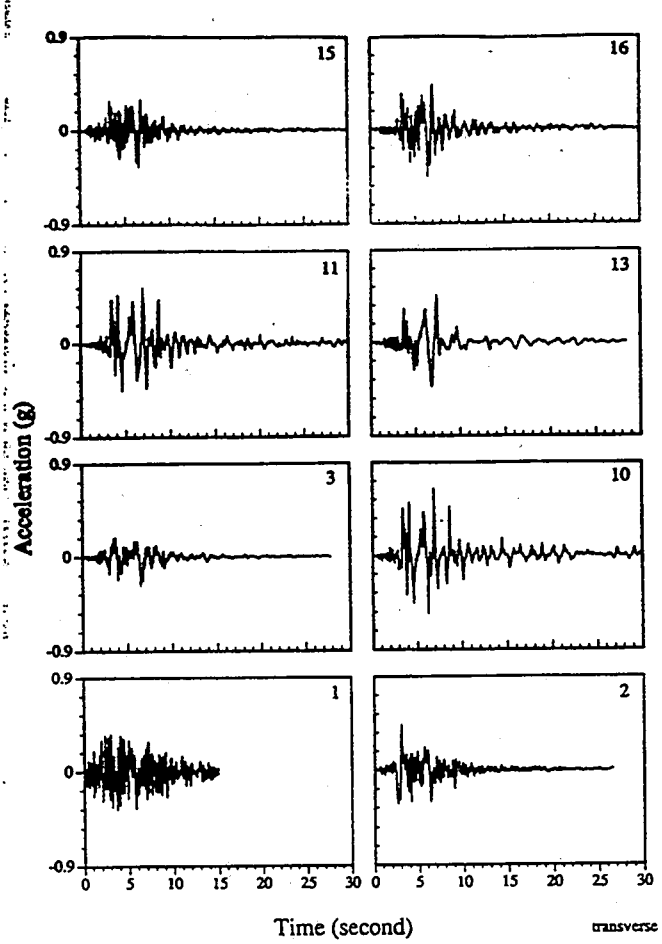

Figure 12. Time history of transverse acceleration recorded at eight stations in the Van Norman Complex.

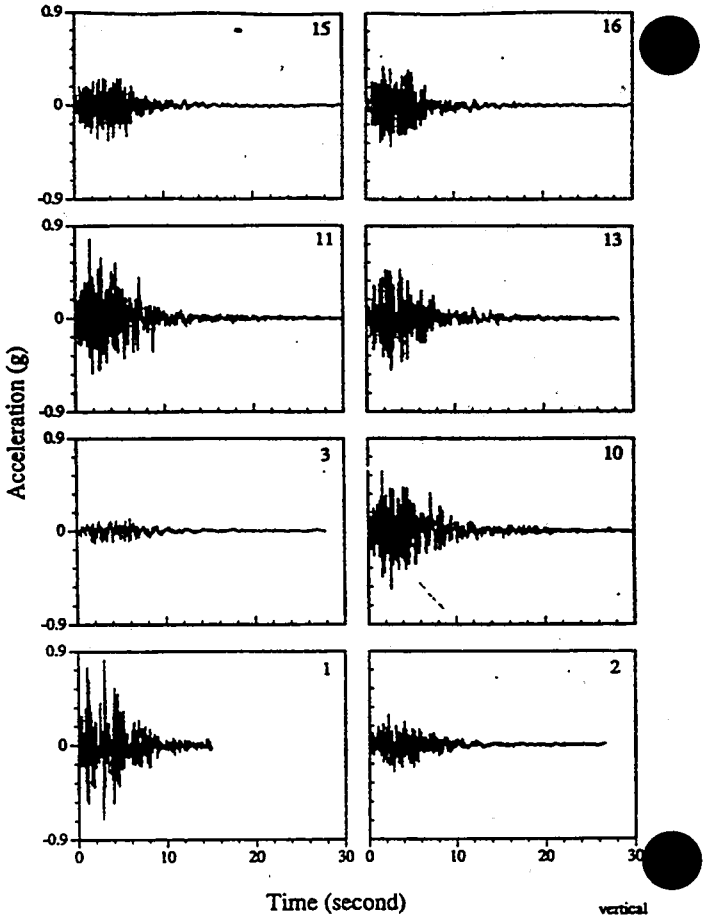

Figure 13. Time history of vertical acceleration recorded at eight stations in the Van Norman Complex.

and the maximum peak value takes place during the first pulse. However, records 2, 10, 11, and 13 display an opposite trend, having the transverse acceleration larger than the longitudinal acceleration. In all records, the accelerations had two preferential directions: longitudinal and transverse directions.

The eight recordings yield consistent information on ground shaking in the VNC. The recordings at a given location are similar, which establishes the proper functioning of the strong-motion instruments. The first and second pulses are clearly observed in all records, regardless of the site conditions. The first pulse with a large acceleration amplitude is especially visible in all the longitudinal records, whereas the second pulse with a long period appears more clearly in all the transverse records. The ground motion in the VNC had a short duration and was dominated by major pulses that radiated from the rupturing fault surface. These pulses carrying a large amount of energy underwent a limited distortion as they went through the shallow soil layers. However, the peak accelerations were lower at the center of the VNC (stations 2 and 3) than in its southern and northern parts.

Figures 15 and 16 compare the normalized spectra measured in the VNC and those used in design by NEHRP. In general, the response spectra measured in the longitudinal direction is different from and exceeds both the S_1 and S_2 design spectra, which are relevant at these locations. This discrepancy includes the filtering of short periods at stations 1, 10, 11, and 13; the spectral peak at stations 2, 3, 10, 11, and 13; and the bump at 2.5 sec in all stations, except for station 1. The filtering of high frequencies may be attributed to the nonlinear behavior of underlying soil layers that was independently observed in the field (Bardet and Davis, 1995a).

Compared with the response spectra in the longitudinal direction, the normalized response spectra in the transverse direction are significantly broader and are also poorly described by the design spectra. Compared with other stations, station 1 has a narrower and higher spectral peak in the transverse direction for low period. In contrast to other spectra, its response spectrum has the bump at 2.5 sec, but in the transverse direction instead of the longitudinal direction. However, this distinct response cannot be attributed to an error in the orientation of station 1, which was independently and carefully verified.

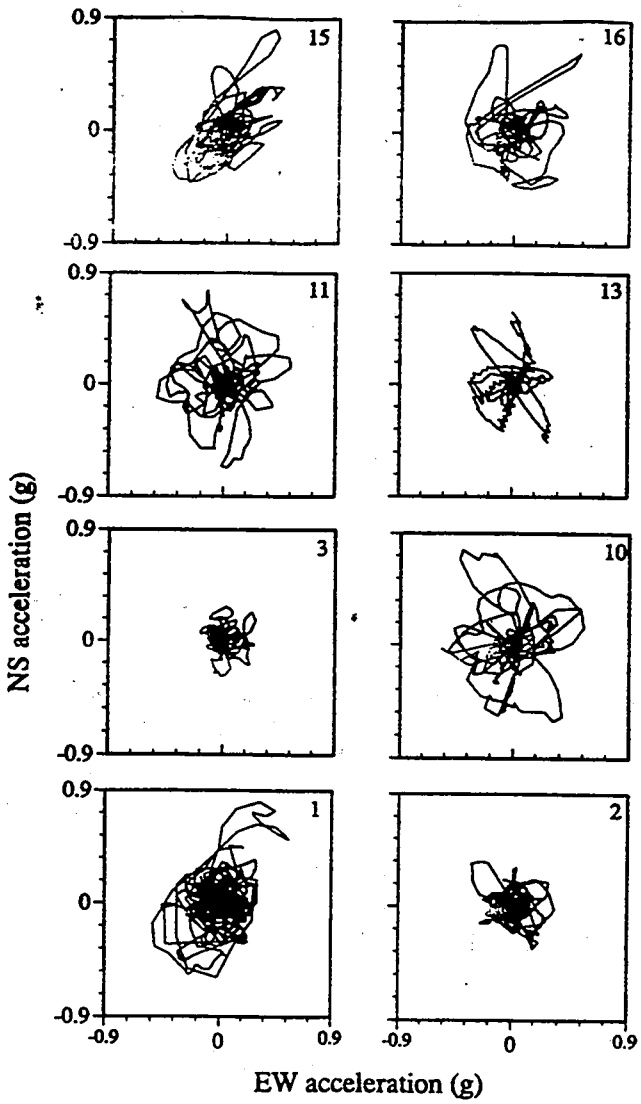

Figure 14. Variation of east–west and north–south components of accelerations at eight stations in the Van Norman Complex.

NEHRP postulates that the normalized acceleration spectra depends mainly on the soil profile type at a given site. Its design spectra were obtained by averaging a large number of measured acceleration spectra, after sorting them into typical soil profile types. However, most of these measured acceleration spectra originated from far-field measurements and not from near-field recordings, which are much more scarce. Therefore, it is not surprising that the NEHRP normalized acceleration spectra do not realistically describe the near-source spectra of the VNC.

During the spring of 1995, all VNC instruments were recalibrated by using a tilt table and were found to have properly been calibrated (Trifunac, 1995b). The orientation, location, and mounting of the instruments were also inspected. Stations 1, 2, 10, and 15 are attached to isolated concrete slabs that are firmly anchored to the ground, away from the influence of any building structures. Station 10 is, however, located over a 3- by 3-m bank of large conduits. Stations 11, 13, and 16 are bolted down to large concrete slabs in the ground floor of low-rise (one to two stories) structures. Station 3 is buried under 30 m of embankment fill. Although some instruments may have been influenced by soil–structure interaction effects, most of them are believed to have correctly measured the free-field ground motions, especially for periods longer than those typical of soil–structure interaction (i.e., about 0.5 sec). Therefore, neither error in instrument calibration nor soil–structure interaction significantly influenced the measurement of ground motion in the VNC.

As shown in Figure 15, there is a definite difference between the longitudinal and transverse spectra (i.e., wider response spectra in the transverse direction). The frequency content of the ground motion recorded at the VNC significantly depends on the direction of ground motion. Similar observations were also made by Campbell and Bozorgnia (1994) for the 1992 Landers earthquake.

The directional frequency content and contributions from permanent ground displacement in near-field strong motion have fundamental consequences in geotechnical and structural engineering. This implies that the dynamic response of structures will be influenced by their orientation relative to the ground motion and by their proximity to causative faults. The transverse ground motion in the VNC activated longer natural periods than its longitudinal component. As shown in Figure 2, the Lower and Upper San Fernando Dam structures of the VNC are almost oriented in the longitudinal and transverse direction of the ground motion, respectively, and therefore responded to ground motions having different frequency contents. The North Dike and Los Angeles Dam of the Los Angeles Reservoir were also subjected to similar effects.

In the far field where the contributions from permanent ground displacement are negligible, directional variations in the amplitudes of response spectra will depend on the radiation patterns of the source and on the properties of the propagation path (Somerville and Graves, 1993). In the near field where ground motions contain contributions from permanent displacement, the long-period part of the Fourier (Trifunac, 1993) and Response Spectra (Trifunac, 1995b) will display larger long-period amplitudes for directions of motion that coincide with the directions of permanent ground displacement.

Tectonic Displacements

During the Northridge earthquake, the fault movement did not create any observable surface rupture in the VNC but caused measurable permanent ground deformations, referred to as tectonic displacements. Tectonic displacements result from a global uplift of the valley floor and mountains in the epicentral region. They are not to be confused with the permanent settlement and lateral displacement of superficial soil

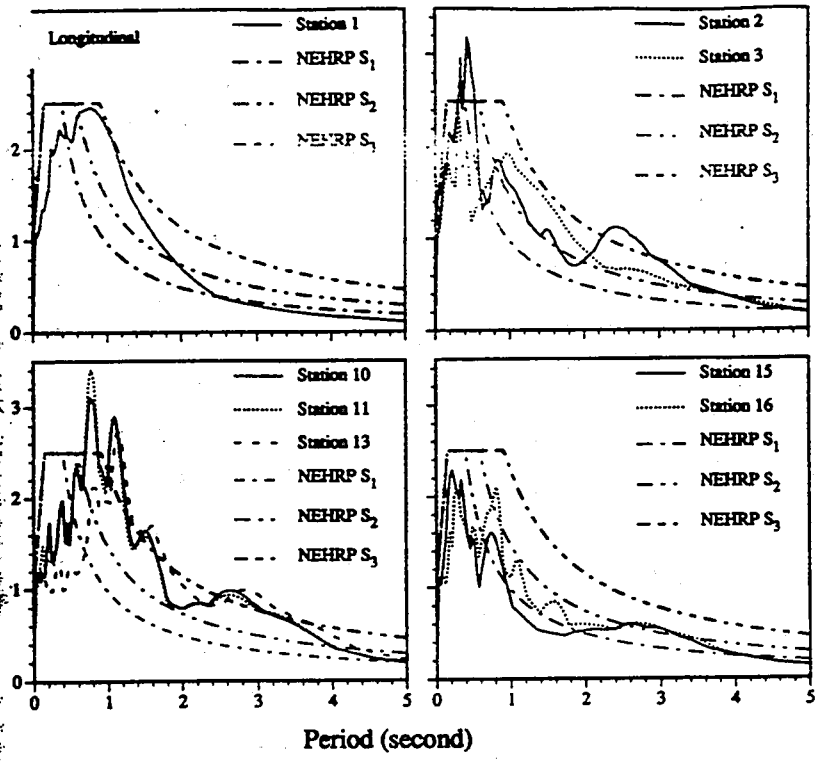

Figure 15. Response spectra of normalized longitudinal acceleration at eight stations in the Van Norman Complex.

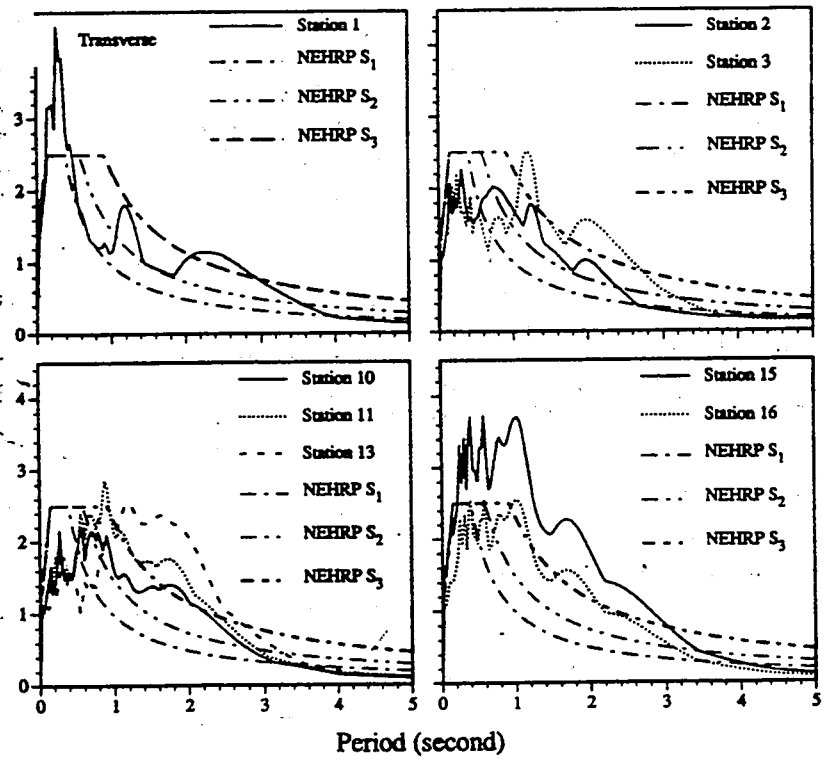

Figure 16. Response spectra of normalized transverse acceleration at eight stations in the Van Norman Complex.

lluvium layers that are induced by ground shaking. ..g the Northridge earthquake, the tectonic uplift exceeded 70 cm in the Santa Susana Mountains and was associated with a horizontal displacement of 21 cm (USGS/SCEC, 1994).

Table 3 lists the tectonic displacements that LADWP measured by using Global Positioning Systems at 19 monument stations in the vicinity of the Los Angeles Reservoir. Most of these displacements were measured on bedrock stations relative to one absolute benchmark point within the

VNC and compared with the original 1977 survey. The displacement was determined by connecting the 1994 postearthquake leveling networks of the city of Los Angeles and Caltrans. Figure 17 represents the horizontal displacement by using vectors and the vertical uplift by using vertical bars. As shown in Figure 17, the vertical uplift on the VNC ranges from 15 to 29 cm, with an average value of 19 cm, and increases to the north and west. The horizontal movement in the southern direction varies from 0.3 to 7 cm, with an average of 3.4 cm, whereas the horizontal movement in the eastern direction ranges from 16 to 24 cm, with an average of 20 cm. The movements in the southern direction increase to the west, whereas those in the eastern direction decrease to the north but are of comparable amplitude on both sides of the reservoir. Compared to the Santa Susana Mountains, the VNC underwent nearly half the vertical uplift and slightly larger horizontal displacements.

Future Research

As shown in Table 3, the average azimuth of tectonic displacement vectors is 99°, which is close to the average azimuth (i.e., 123°) for the transverse direction of strong-motion recordings. The directional dependence of acceleration response spectra were probably related to the tectonic displacements in the VNC. However, these displacements contain periods longer than those measurable by the strong-motion instruments that recorded this event (Amini *et al.*, 1982). Therefore, more detailed future work must be carried out to interpret the causes for differences in the amplitudes of long-period spectra. At present, estimates of long-period response amplitudes can be estimated by approximate extrapolation of spectral amplitudes (Trifunac, 1995b), by asymptotic scaling relative to the static displacement surrounding the fault (Trifunac, 1993), and by sophisticated correction and filtering techniques (e.g., Iwan *et al.*, 1985).

The possible causes for the sudden variations in peak ground and spectral accelerations among VNC stations may be mixed and include the following: (1) radiation pattern, interference, and directivity from waves arriving from different parts of the fault (at such small distances, we cannot assume a point source approximation); (2) complicated mixing of the above effects by inhomogeneous geological media between source and stations (Novikova and Trifunac, 1994; Trifunac *et al.*, 1994); and (3) interference patterns caused by local geologic and soil inhomogeneities (Trifunac, 1990), including irregular sedimentary basins and local topography.

Based on the 1994 recordings, there is also a need for reassessing the ground motion in the VNC during the 1971 San Fernando earthquake, which was estimated indirectly by Scott (1973). In 1994, two seismoscopes recorded the ground shaking. One seismoscope was located on the crest of the Bypass Reservoir Dam, whereas the other one was situated on the abutment of the Bypass Reservoir Dam and the Los Angeles Dam, next to a strong-motion recording. These seismoscopes and strong-motion records could be useful to reevaluate the ground motion at the site during the 1971 San Fernando earthquake and to assess the validity of past analyses on the Lower San Fernando Dam (e.g., Ziemkiewicz *et al.*, 1990).

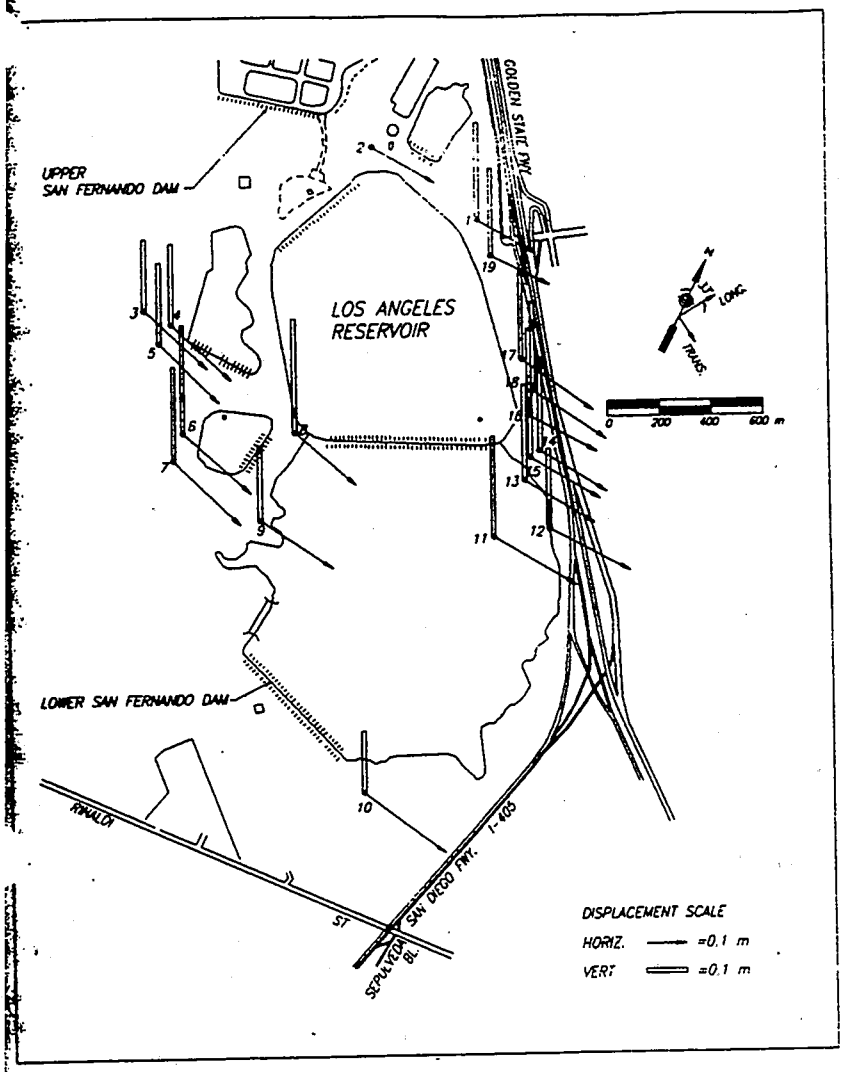

Figure 17. Horizontal and vertical tectonic movement in the Van Norman Complex.

As previously mentioned, this article reports partial results of a larger research program. At the time of this writing, only a few accelerograms have been processed, and the other recordings need to be processed as well. Future analyses will concentrate on the effects of ground motions on permanent ground deformation and will attempt to explain the ground displacements and responses of geotechnical structures in the VNC.

Conclusions

During the 1994 Northridge earthquake, the Van Norman Complex yielded an unprecedented number of recordings with high acceleration, in the close proximity of the fault. These strong-motion recordings clearly exhibited the main pulses generated by the fault that ruptured toward and beneath the complex. One station at the south of the complex produced the largest velocity ever instrumentally recorded (177 cm/sec), which resulted from a 0.86 g peak acceleration with a low frequency. Throughout the complex, the horizontal accelerations reached maximum peak values ranging from 0.56 to 1.0 g, except for the complex center where the maximum peak acceleration remained below 0.43 g. The vertical acceleration reached maximum peak values comparable with those of the horizontal acceleration. The maximum peak horizontal accelerations were also anisotropically distributed, with the largest peak values in the direction of the fault rupture. The acceleration response spectra in the longitudinal and transverse directions were significantly different. Such a difference, which has been more documented in engineering seismology (e.g., Campbell and Bozorgnia, 1994) than in geotechnical earthquake engineering, indicates that the frequency content of the ground motion in the Van Norman Complex was directionally dependent.

Ground-Motion Variability at the Highway 14 and I-5 Interchange in the Northern San Fernando Valley

by Lawrence Hutchings and Steve Jarpe

Abstract The purpose of this article is to analyze possible causes for failure of the structures at the Highway 14 and I-5 interchange in the northern San Fernando Valley following the magnitude *M* 6.7 San Fernando earthquake on 9 February 1971 and the *M* 6.7 Northridge earthquake on 17 January 1994. This interchange consisted of a series of structures up to 600-m long; during the 1971 and 1994 earthquakes, several of these structures separated along expansion joints and collapsed.

To analyze the possible causes of failure, we recorded aftershocks at and near the interchange for 2 weeks following the 1994 earthquake. The aftershock recordings reveal a substantial relative spectral amplification (in the 1- to 10-Hz range) of a factor of 3 to 6 for sites located at the interchange (which is situated on sandstone) relative to a nearby rock (gneiss) outcrop site. Sites within the interchange area have a variation in amplification of a factor of 2 to 4 in the 1- to 10-Hz range. Also, substantial secondary arrivals were generated at two locations in the interchange area. We attribute variations in ground motion at the interchange to be due to variations in the composition of the sandstone and to topographic effects.

We computed the linear-response strong ground motion for three sites at the interchange from the 1971 and 1994 main events using aftershock recordings of the Northridge earthquake from three sites (the south and north abutments of the southbound connector of Hwy 14 to I-5 and a central location to the interchange) as empirical Green's functions. The same source events are used for all three sites for a particular synthesis so that differences between synthesized strong ground motion are due to differences in location, geology, and topography of the three sites. Source rupture models are obtained from independent studies. We estimate (1) peak acceleration to have been near 1 *g* for both earthquakes, due to the topographic and geologic conditions and the geometry of the fault rupture; (2) differential displacement across the north and south extremes of the area from the Northridge earthquake to have been about 70 cm longitudinal and 40 cm transverse to the Hwy 14 to I-5 connector; (3) differential displacement across the north and south extremes of the area from the San Fernando earthquake to have been about 25 cm longitudinal and 20 cm transverse; and (4) relative motion to be fairly incoherent for frequencies above 0.5 Hz. These observations are attributed to local geologic and topographic conditions and to wave passage effects and could have contributed to collapse of structures during these earthquakes.

Introduction

In this article, we analyze possible causes for failure of the structures at the Highway 14 and I-5 interchange in the northern San Fernando Valley following the magnitude *M* 6.7, 9 February 1971 San Fernando earthquake and the *M* 6.7, 17 January 1994 Northridge earthquake. Strong ground motion was not recorded at the interchange for either earthquake.

In 1971, at the time of the San Fernando earthquake, the interchange was under construction. Primary damage occurred to the 411-m-long south connector, which was essentially complete (Plate 1a). The gap in the photo is due to the collapse of two 53-m continuous spans that started and terminated at hinge seats (Elliott and Nagai, 1973). These two spans were supported and connected by a 2- by 3-m wide,

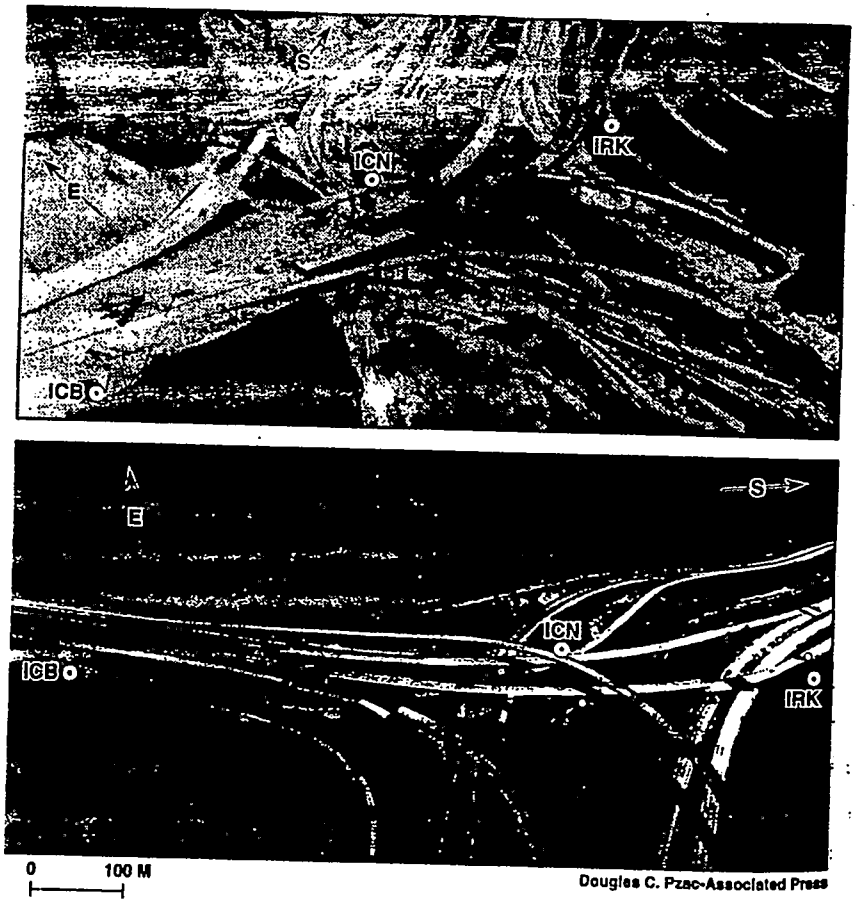

Plate 1. (a) An aerial view of the interchange following the 1971 San Fernando earthquake (from Elloitt and Nagai, 1973). The interchange was under construction. The main damage was to the south connector, which was complete at the time. The south connector is the curved structure next to station IRK and merges near station ICB. (b) An aerial view of the interchange hours after the 1994 Northridge earthquake (photo is computer enhanced near ICB). The south connector once again sustained failure. The structure that merges with the south connector near station ICB failed during this earthquake but was undamaged during the 1971 earthquake.

43-m-high column. It is theorized that the earthquake induced lateral deflection toward the outside of the curved ramp. This deflection opened up the structure, causing the northern span to fall off its 36-cm-wide hinge seat. As this span fell, it pulled down the column and the southern span (Elliott and [illegible]).

Subsequent to the 1971 failure, the interchange was completed using the original plans. New designs were prepared for the few columns that had not been completed and for those that required reconstruction. The spacing of transverse reinforcement in the new designs was reduced. Restrainers were added at expansion hinges during the final stages of construction (EERC, 1994). During the 1994 earthquake, several of those structures also separated and failed along hinge seats (Plate 1b). In particular, the south connector failed once again. Also, the north connector, which merges at ICB, failed, but it did not fail during the 1971 earthquake. Following the 1994 earthquake, the interchange was rebuilt once again. In this article, we only analyze ground motion, not the structural response to ground motion.

To analyze possible causes of failure, we recorded aftershocks at and near the interchange for 2 weeks following the 1994 earthquake. The three sites at the interchange were at the south and north abutments of the southbound connector of Hwy 14 to I-5 (600 m apart) and a central location to the interchange (300 m from either abutment). Spectral ratios of the aftershock recordings are analyzed to examine topographic and geologic effects on seismic wave propagation. We also compute linear-response strong ground motion for the three sites at the interchange from the 1971 and 1994 main events using aftershock recordings as empirical Green's functions. The same source events are used for all three sites for a particular synthesis so that differences between synthesized strong ground motion are due to differences in location, geology, and topography of the three sites. Source rupture models are obtained from independent studies, but synthesized ground motion are not validated with recorded data. No strong-motion recorders were operating at the interchange during either earthquake. Synthesized ground motion and spectral ratios reveal a significant differential ground displacement across the interchange and greater-than-expected ground motion that may have occurred from the 1971 and 1994 main events.

Recent advances in structural design require realistic input ground motion to fully test structural designs (McCallen *et al.*, 1994). Several factors affecting strong ground motion should be considered for the structural design of long-span structures. Synthesized seismograms should include the effects of (1) directivity and energy radiating from different portions of the fault resulting from finite rupture, (2) wave passage incoherency resulting from the time lag of wave propagation across the structures, (3) wave amplification resulting from local geologic and topographic conditions, and (4) high-frequency incoherency resulting from different scattering effects of the geology and topography along the structures. The approach to synthesizing strong ground motion used in this article (Hutchings, 1991, 1994) explicitly accounts for these effects on strong ground motion and provides realistic synthetic strong ground motion by using empirical Green's functions recorded at specific locations along the structure and by modeling kinematic rupture.

The Northridge and San Fernando earthquakes occurred within a complex distribution of east–west-trending thrust faults beneath the San Fernando Valley region and along the frontal thrust fault system of the Santa Susanna Mountains. Figure 1 shows the geology of the San Fernando Valley area and the epicenters and rupture areas of these recent earthquakes. The San Fernando and Northridge earthquakes had a similar geometric relationship to the Hwy 14 and I-5 interchange but a substantially different spatial relationship (Fig. 1). In both earthquakes, the interchange was very near the rupture areas, and the effects of finite rupture were significant. The San Fernando earthquake had a hypocenter to the north and ruptured updip (possibly on two faults) to the south with primarily thrust fault motion (Hanks, 1974). The Northridge earthquake hypocenter was to the south and ruptured updip to the north, also with thrust motion (Wald *et al.*, 1996). The San Fernando earthquake ruptured to the surface (Kamb *et al.*, 1971); the Northridge earthquake did not (Hudnut *et al.*, 1994; USGS Staff, 1994a, 1994b) and, therefore, is referred to as occurring on a blind thrust (SCEC, 1995).

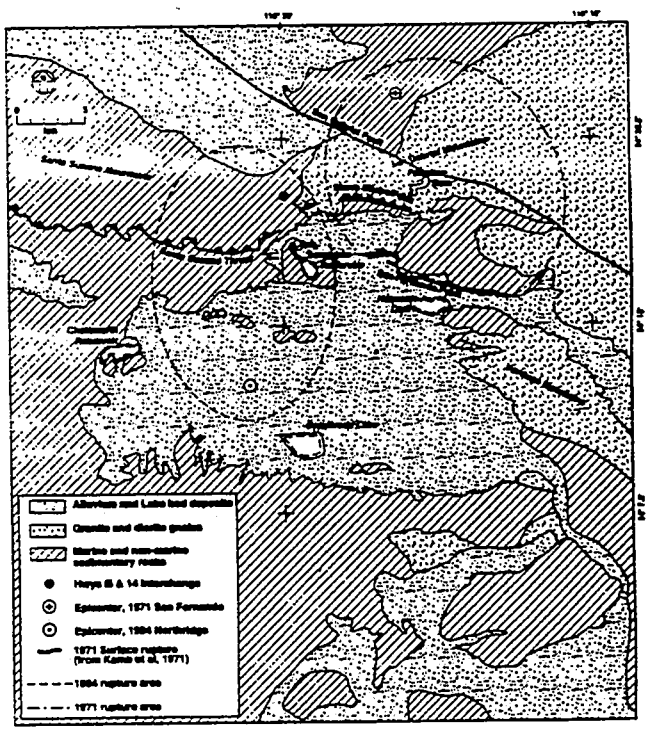

Figure 1. The geology of the San Fernando Valley area and the locations and rupture areas of the 1971 San Fernando earthquake and the 1994 Northridge earthquake. (Geology modified from Jennings and Strand, 1969.)

Instrumentation, Site Geology, and Topography

Immediately following the 1994 earthquake, Lawrence Livermore National Laboratory seismologists initiated a rapid deployment of weak- and strong-motion seismic recorders. The weak-motion recorders consisted of 16-bit fixed-gain instruments with 1-Hz free-period, high-gain Teledyne Geotech S-13 seismometers. The effective recording bandwidth (flat to velocity) was 0.2 to 50 Hz. The individual seismometer constants (free period, damping, and seismometer gain) were determined from step calibration pulses and are correct to within 5%. Table 1 lists the stati locations, ID's, geology, and period of operation.

Figure 2 shows the geology surrounding the interchan area and the location of instruments. The interchange a is composed of sandstone that extends a distance of at le 1.5 km from the interchange area. Gneiss is the closest ba ment rock outcrop at site IGN. It is hard and coherent wi some healed fractures and would be classified as a "ha rock" class A site by the Boore *et al.* (1993) classificati The sandstone within the interchange area is interbedd with layers varying in consistency and thickness from c

Table 1
Aftershock Recording Sites

ID	Operation	Latitude/ Elevation	Longitude/ Components	Geology	Description
ICN	1911 21 Jan 1931 03 Feb	34.3356 450 m	118.5060 u.n.e.	friable to semi-friable sandstone, medium grained	center of interchange
IRN	0044 20 Jan 1800 21 Jan	34.3360 450 m	118.5128 u.n.e.	coherent to semi-friable sandstone, medium grained	600 m west of interchange

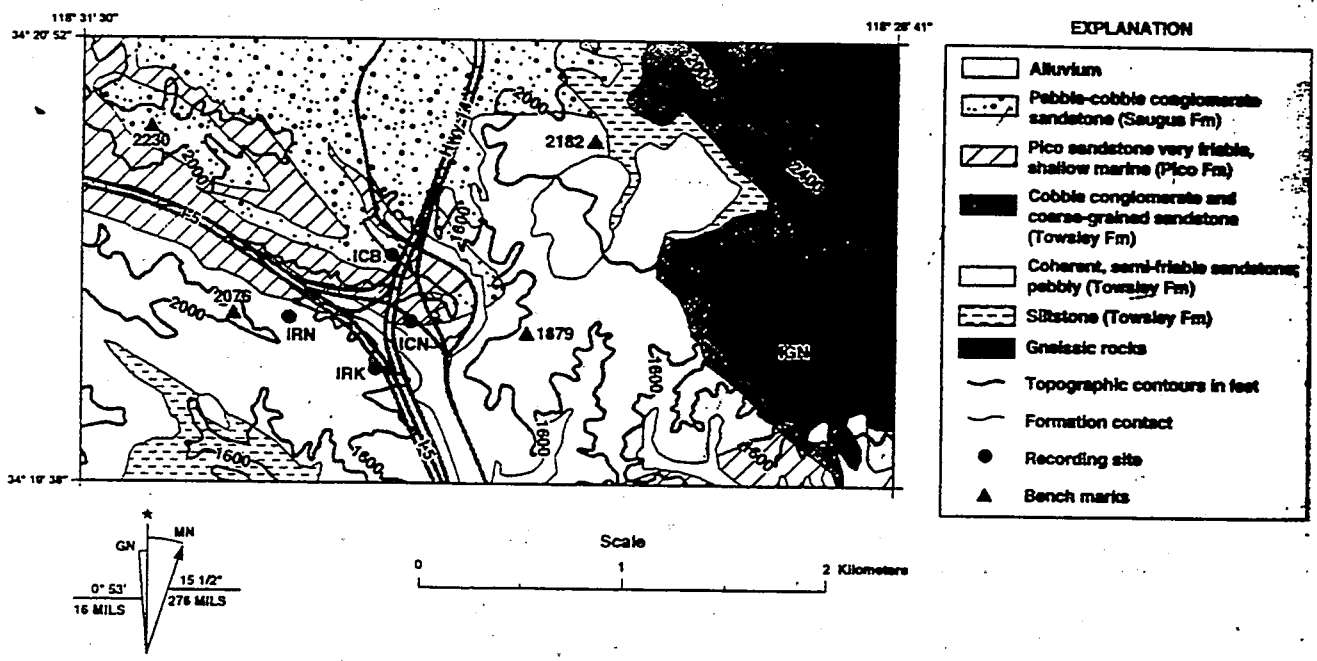

Figure 2. Geology and topography of the interchange area and the location of instruments. The interchange is situated in a topographic basin, and the geology is sandstone of varying composition. Gneiss rock outcrops at a distance of about 1.8 km and is assumed to be the basement structure for the area.

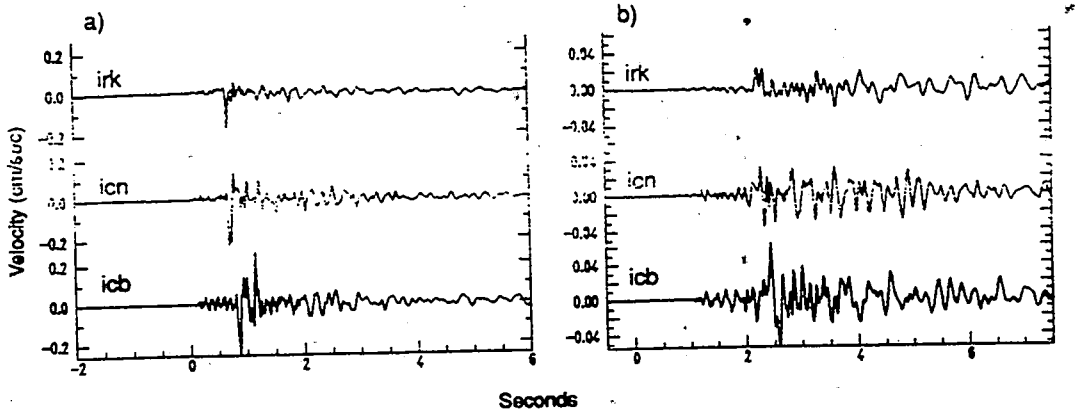

Figure 3. Seismograms at the three sites (a) from a magnitude 2.7 earthquake with hypocentral distance of 5 km and (b) from a magnitude 2.1 earthquake with hypocentral distance of 10 km.

few centimeters to 5 to 10 m. The composition of sandstone at each instrument site differs, but they all would be classified as "class B" soft-rock sites by the Boore *et al.* (1993) classification. The sandstone at the IRK and IRN sites is medium grained and coherent to semi-friable and contains significant amounts of gypsum. By contrast, the sandstone from site ICB is a weathered pebble-cobble conglomerate and contains the swelling clay, smectite, at a concentration of 10 to 20% by volume. The sandstone at the ICN site is medium grained and friable to very friable.

Laboratory measurements of shear modulus and attenuation were made at seismic frequencies and strain levels for surface samples from the instrument locations to determine if material properties contributed to site variability (Brian Bonner, Lawrence Livermore National Laboratory, personal comm., 1995). Tests were conducted with a torsional oscillator (Bonner and Wanamaker, 1991), which applies a uniaxial load of 1 to 3 MPa to simulate overburden. Results show important differences in the shear response of these rocks for shear strains of 1×10^{-6} to 5×10^{-6}, which are low enough to correspond to weak motion. Shear moduli for the IGN gneiss and the IRK and ICB sandstones are 14.5, 12.5, and 6 GPa, respectively, for frequencies between 4 and 16 Hz. Shear attenuations (Qs^{-1}) are more scattered, ranging from 0.015 to 0.03 in this frequency range. The ICB sandstone and the IGN gneiss have comparable attenuation, and IRK has the highest. The combination of low modulus and relatively low attenuation for the ICB sandstone is unexpected. However, the ratio of shear moduli for the ICB and IRK sandstones is 0.48. If this difference is representative of the rocks in the vicinity of the stations, it could account for a factor of two relative amplification of shear waves between the IRK and ICB sites.

The topography of the interchange area is unusual. It sits at the confluence of two valleys with high peaks at three points between the valleys creating a topographic basin (Fig. 2). The spatial dimensions of the basin are near the wavelengths of seismic energy (0.5 to 2.0 km) and suggest that

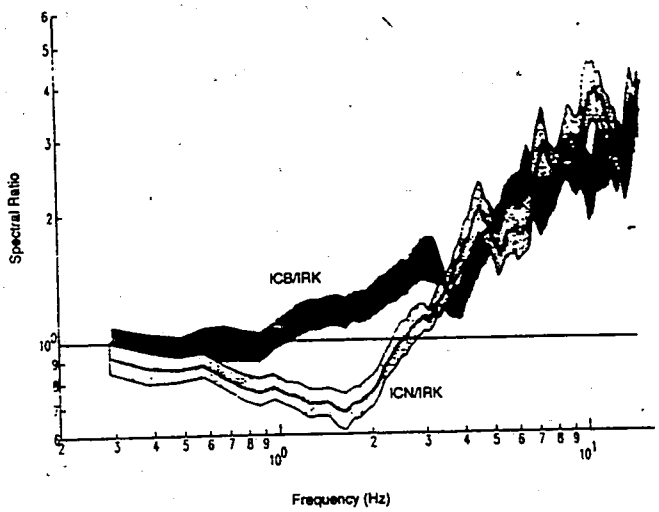

Figure 4. The spectral ratio and the 5 and 95% confidence limits for several events recorded at site ICB relative to IRK and at site ICN relative to IRK.

topography may play a significant role in amplification and incoherency of seismic wave propagation. Craig Schultz (Lawrence Livermore National Laboratory, personal comm., 1995) conducted a numerical experiment to determine whether topography in the region of the Hwy 14 and I-5 interchange contributes significantly to differential motion on the structure. He developed a simple two-dimensional topographic model of the Hwy 14 and I-5 interchange region using sinusoidal ridges with the same characteristic height, spatial wavelength, and separation as topography in the vicinity of the interchange (Schultz, 1994).

Schultz found that the peak-to-peak amplitude recorded at the free surface, given a plane incident shear wave, shows that an amplification factor of 2 can be easily achieved near the flank of the hills relative to the flatter portions of the basin and that dramatic amplification and deamplification of shear-wave energy in the 1- to 10-Hz frequency range can

occur over short distances. Schultz concludes that this simple model is most likely a lower limit on the differential motion that could occur along the Hwy 14 and I-5 interchange as a result of topography and that topography could account for at least a factor of 2 variation in amplitudes across the interchange area.

Site-Specific Site Response

Comparisons of recordings of small earthquakes ($M < 3.0$) across the interchange are used to examine the combined site geologic and topographic effect. Figure 2 shows the location of recording sites IRK, ICN, and ICB, which form a rough north–south line along the axis of the interchange. Figure 3 shows seismograms at the three sites from a magnitude 2.7 earthquake with hypocentral distance of 5 km and from a magnitude 2.1 earthquake with hypocentral distance of 10 km. These events are effectively point sources. The seismic energy has traveled along the same path from the earthquake to the interchange. The differences in the recordings are due to differences in geology and topography at the recording sites. It is apparent that there is considerable amplification in the site response at ICN and ICB as compared with that at site IRK. Also, it is apparent that relatively large secondary arrivals are being developed at the ICN and ICB as compared with those at site IRK.

Figure 4 shows the spectral ratio and the 5 and 95% confidence limits for several events, following the procedures outlined by Jarpe *et al.* (1989). The amplification at site ICB relative to IRK increases for frequencies above 1 Hz to about a factor of 3 at 10 Hz. The amplification of site ICN relative to IRK is the same as that for ICB relative to IRK, except in the 0.6- to 4.0-Hz range. These plots show that the three sites have significantly different amplification factors that range from a factor of about 2 to 4 over the 300- and 600-m separations. This is consistent with the site geology and topography effects predicted by Bonner and Schultz above. There were not enough common events to examine spectral ratios at site IRN.

Figure 5 shows seismograms from sites IGN and IRK for two events. This shows that there is a significant amplification of seismic waves and substantial secondary arrivals in the interchange area relative to the hard-rock site. Figure 6 shows spectral ratios for the two sites. There were only six events to obtain the spectral ratio, so confidence limits are poorly defined. The spectral ratios show that the IRK site amplifies seismic energy up to a factor of about 6 relative to site IGN, in the 2.0- to 10-Hz range; lower-frequency values are very unreliable. This indicates that in addition to the variation across the sandstone in the interchange area, the geology of the interchange is such that it amplifies energy by about a factor of 3 to 6 (in the 1- to 10-Hz range) relative to this hard-rock site.

Recording Site Variation

If important variations in amplification and waveforms occur over short distances, (300 to 600 m), we must consider whether they are also important over even shorter distances (50 to 100 m) (i.e., does it matter where the sensors are placed). To test this, we set up an experiment to record events at site IRK and at another site 50 m east on the abutment to the Hwy 14 connector, as well as at site ICN and at another site 100 m west, farther into the ravine. The abutment is a very massive concrete structure and is imbedded in the sandstone. It is on the same sandstone but not the same layer as IRK. The alternate site to ICN is also in the center area and on the same sandstone as ICN but on the other side of a small gully. Both alternate sites are shown in Plate 1a as small white circles without ID initials. Figure 7 shows a single component of a recording at IRK and the alternate site. The similarity of waveforms is obvious. It is interesting that the maximum peak is different by almost a factor of 2 between the two sites. The waveforms between the ICN site and the alternate site were different, but the character was the same, and the spectral amplifications relative to IRK were essentially the same. The answer to the question based on the limited data here is that variations in this area are sig-

ificant over short distances (300 to 600 m) but not over y short distances (50 to 100 m).

Synthesized Ground Motion

We synthesized the ground motion over the frequencies 3 to 25.0 Hz using empirical Green's functions (Hutchings nd Wu, 1990; Hutchings, 1991) and combined this with a nthesis over the frequencies 0.0 to 0.3 Hz using synthetic reen's functions. Both syntheses were calculated using the ogram EMPSYN (Hutchings, 1988), which uses the reen's function summation approach (Heaton, 1982) to odel kinematic rupture models (Hutchings, 1994). Syn- tic Green's functions were calculated using the reflectiv- code (Kennett, 1983) for a one-dimensional velocity ucture obtained from Hauksson *et al.* (1995). T... syn- tic Green's functions do not include near-field terms.

The empirical Green's functions in this study are small enough that they occur as effectively impulsive point dislocation sources. This allows for an explicit solution to the representation relation with empirical Green's functions (Hutchings, 1994). Hutchings and Wu (1990) found that aftershocks of the San Fernando earthquake with moment less than about 1.5×10^{21} dyne-cm (dependent upon site geology) were effectively point sources for rock and alluvial sites. Only aftershocks of the Northridge earthquake that meet this criterion are used here as empirical Green's functions.

Syntheses are calculated at sites IRK, ICN, and ICB, where the empirical Green's functions were recorded. The site-specific empirical Green's functions include the total effect of whole path and site geology, wave amplification, and topography. Also, the same events were used to obtain empirical Green's functions for all three sites. Thus, the synthesis explicitly accounts for the effect of wave passage, wave amplification, and high-frequency incoherency.

Kinematic rupture models used here are simple characterizations of actual rupture. They rely on moment, fault geometry, hypocenter, rupture roughness, rupture velocity, healing velocity, asperities, and a Kostrov slip model. These parameters are described in Hutchings (1991, 1994). Jarpe and Kasameyer (1996) found that this simple characterization of the source, with parameters set from independent studies, described the observed strong ground motion for the Lama Prieta earthquake. Hutchings (1994) modeled observed records from the San Fernando earthquake using such simple rupture models along with parameters established from independent studies. Here, independent studies are used to establish these parameters for a rupture model of the Northridge earthquake. The rupture model M1608 from Hutchings (1994) is used for the San Fernando earthquake.

The slip distribution and geometry for both rupture models is shown in Figure 8. The model for the San Fernando earthquake has rupture on two faults as subevents: the deep rupture has moment 0.5×10^{26} dyne-cm, and the shal-

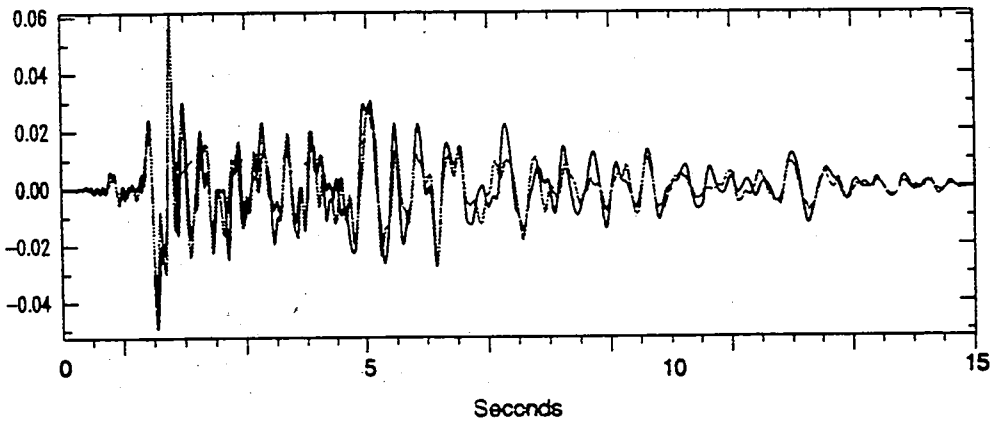

Figure 7. The east component of a recording at IRK (solid line) and the alternate site (dotted line). The alternate site is on the abutment and is shown as the open circle shown near IRK in Plate 1b.

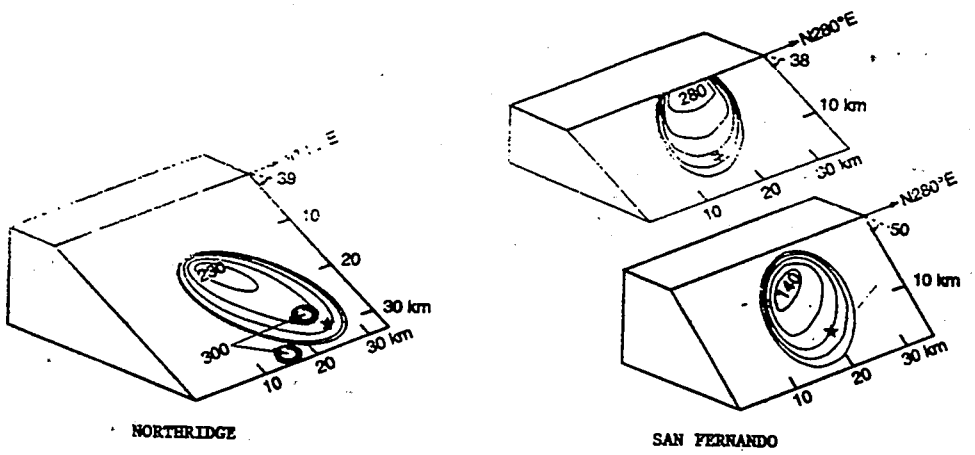

Figure 8. The slip distribution and geometry for the rupture models for the Northridge and San Fernando earthquakes. The San Fernando rupture model has rupture on two subevents. Rupture initiates on the deep rupture and then initiates on the shallow rupture 2 sec later. The stars show the initiation points.

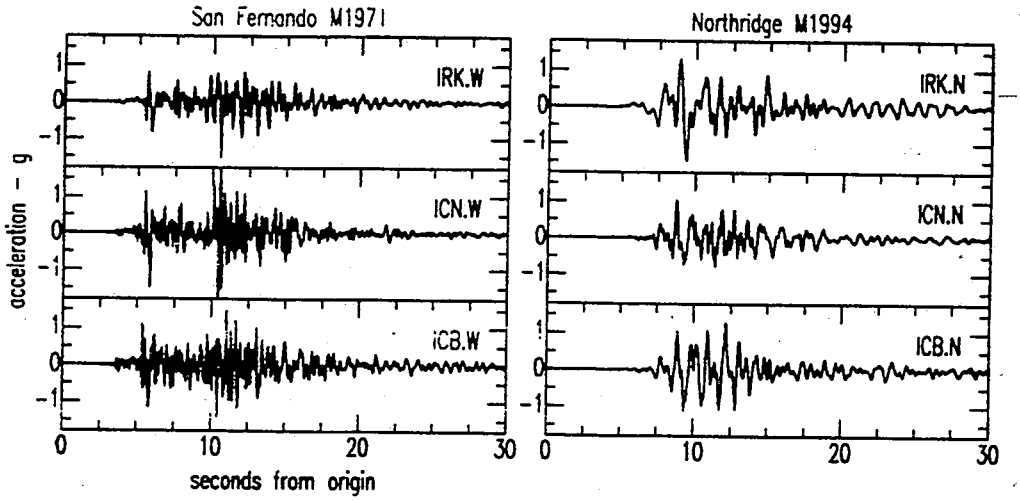

Figure 9. Synthesized acceleration at the three sites for the source models shown in Figure 7. Only the west component is shown for the 1971 earthquake and only the north component is shown for the 1994 earthquake. One excursion on the ICN.W component for the San Fernando exceeds 2 *g*.

low rupture has moment 1.0×10^{26} dyne-cm. Both have a focal mechanism solution with strike N280°W, slip vector 100, and dips of 38° N and 50° N for the shallow and deep portions of the fault surface, respectively. The solution uses the Kostrov slip rupture model with healing and 50% roughness. Nine empirical Green's functions were used for the upper rupture, and 10 were used for the lower rupture.

The source rupture model used for the Northridge earthquake used in this study (Fig. 8) is described. The hypocenter of the main event was determined by Hauksson *et al.* (1995) to be 34.2092°N, 118.5407°W 18.7 km. The moment is 1.4×10^{26} dyne-cm, obtained as an average of studies by Dreger (1994), Wald *et al.* (1995), and Song *et al.* (1995) and a slip rake of 105° from the average of these studies. The fault plane orientation is that derived by Hauksson *et al.* (1995) from aftershock distribution: N119°E, 39°S. The fault plane fits the average of the focal mechanism of the above studies. The slip distribution is a first-order approximation of the slip distribution determined by Dreger (1994) and Wald *et al.* (1995); both had similar results. The long axis of the slip contours and the major axis of the elliptical rupture area are oriented ~30°W of the updip direction and are aligned due north. The ellipse has an eccentricity of 0.8 with a major axis of 25.0 km and minor axis of 15.0 km. It approximates the area outlined by a deficit of aftershocks plotted by Hauksson *et al.* (1995) and is consistent with the area of slip determined by Dreger (1994). The stress drop modeled is 75 bars, and we used 20% roughness. Eighteen empirical Green's functions were used.

Figure 9 shows the resulting accelerograms at the three

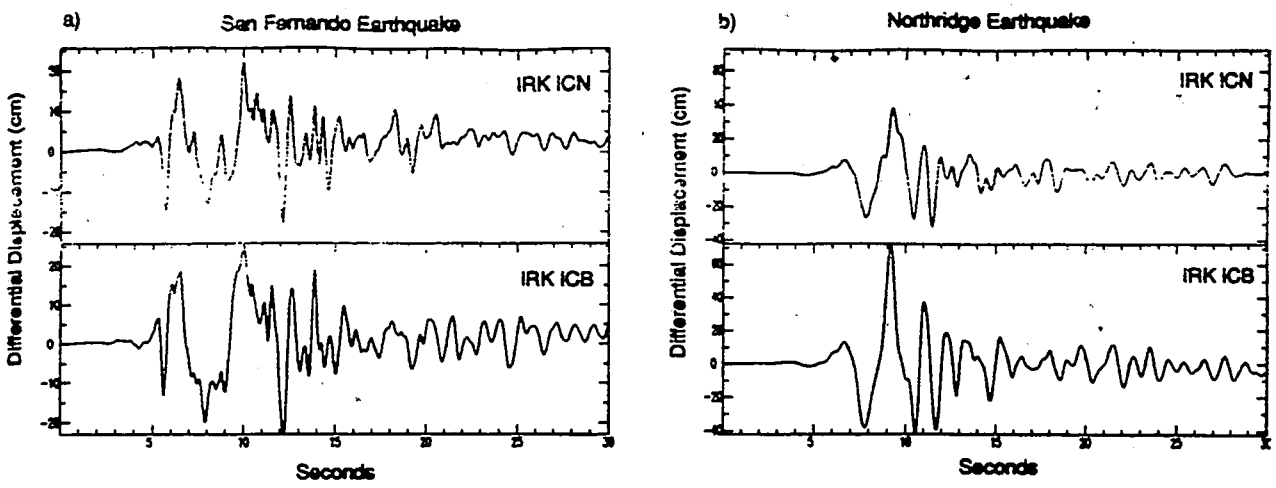

Figure 10. The relative displacement in the north–south direction between site pairs IRK and ICN (top) and IRK and ICB (bottom): (a) San Fernando earthquake and (b) Northridge earthquake.

sites from both earthquakes. It is interesting that the peak acceleration varies by a factor of almost 2 among the three sites for each earthquake. Over this short distance range, peak acceleration can vary significantly. It is assumed that this is a result of the topographic and geologic conditions and the chance occurrence of constructive and destructive interference. Also, note that more high frequencies occur at sites ICN and ICB than at site IRK. Both of these effects are entirely due to differences in site geologic response. The synthesized accelerograms for the San Fernando earthquake have higher-frequency content than those from the Northridge. This is partially a result of the San Fernando earthquake rupturing to the surface and actually rupturing closer to the interchange than did the Northridge earthquake, which ruptured only to within 6 km of the surface. Also, the rupture model used for the San Fernando earthquake has a higher percentage of roughness to rupture, which enhances the high-frequency energy.

Estimated Differential Ground Motion

The relative ground motion among the three sites along the interchange can be computed from the synthesized seismograms. Figure 10 shows the relative displacement in the north direction between site pairs for the two earthquakes. The north–south direction is longitudinal to the Hwy 14 connector that separated along expansion joints for both earthquakes. Sites IRK and ICB are at the two extremes of the interchange and show a relative displacement of up to 25 cm for the San Fernando earthquake and 70 cm for the Northridge earthquake. Site ICN is in the central area of the interchange. Differential displacements of up to 20 cm are computed for the San Fernando earthquake and up to 40 cm for the Northridge earthquake. These represent strains of up to about 10^{-3} across the interchange. The lower differential motions for the San Fernando earthquake is surprising since the interchange is closer to the high-amplitude displacements in the San Fernando rupture model. However, the two-subevent model for the San Fernando earthquake results in less long-period energy that contributes to the relative displacements.

Figure 11 shows the coherence (normalized cross-correlation) of the synthesized accelerograms as a function of frequency. Remember, synthesized seismograms used the same source events as Green's functions to limit variability resulting from different source events. Seismic energy is fairly incoherent for both earthquakes for frequencies above about 0.5 Hz. Lower-frequency calculations are unreliable due to signal-to-noise ratio.

Conclusions

We analyzed records of small earthquakes ($M < 3.0$) at three locations separated by 300 to 600 m in the interchange area and a fourth location 2 km east. The entire interchange area is situated on interbedded sandstone of varying consistencies and is surrounded by ridges of the Santa Susana and San Gabriel Mountains. The aftershock recordings reveal a substantial relative spectral amplification of up to a factor of 4 across the interchange area. Also, substantial secondary arrivals are generated at two locations in the area. We attribute these effects to variations in the composition of the sandstone and topographic variations. Also, spectral ratios for events recorded at the interchange and at a hard-rock site at a distance of 2 km show that the entire interchange area amplifies seismic waves up to about a factor of 6 relative to the reference site.

We used the aftershock recordings of small earthquakes as empirical Green's functions and synthesized strong ground motion for both the San Fernando and Northridge

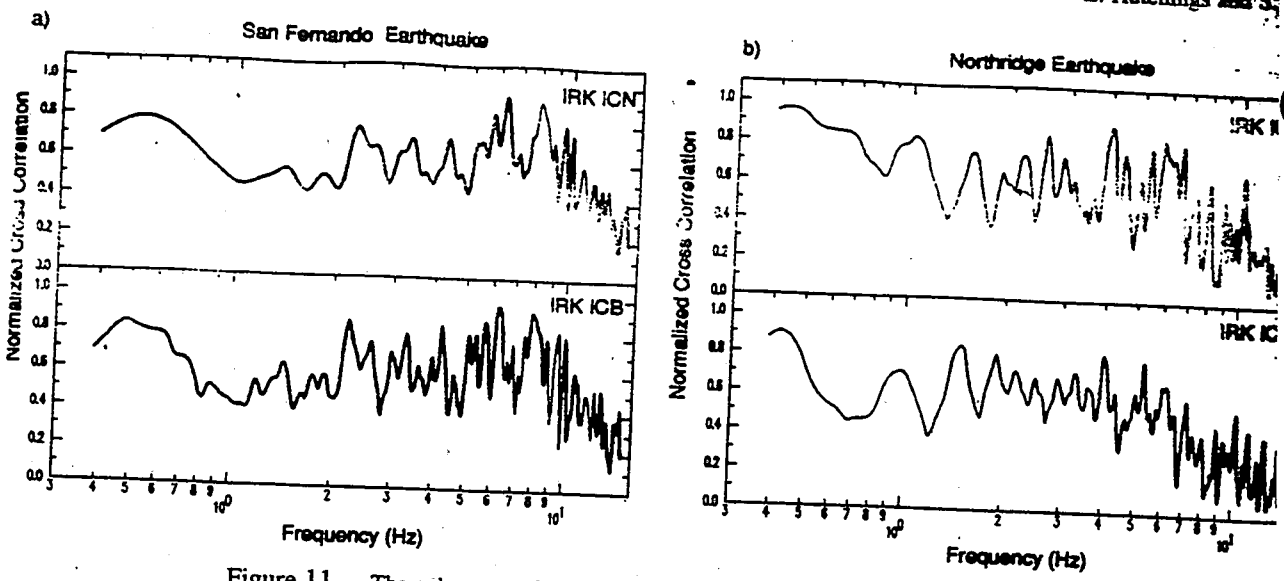

Figure 11. The coherence of the acceleration as a function frequency: (a) San Fernando earthquake and (b) Northridge earthquake.

earthquakes at three sites in the interchange area. Results presented here are based on an assumption that the geology of the interchange area remained linear in its response to the main event. We do not claim to have synthesized the exact ground motions that occurred during these earthquakes, but we do claim to have sufficiently accounted for the factors effecting strong ground motion to speculate what the effects on the structure might have been. From our synthesized ground motion, we estimate (1) peak acceleration to have been near 1 *g* for both earthquakes due to the topographic and geologic conditions and to the geometry of the fault rupture; (2) differential displacement across the north and south extremes of the area to be up to about 25 cm for the San Fernando earthquake and up to about 70 cm for the Northridge earthquake, due to wave passage effects and local geologic and topographic conditions; and (3) relative motion to be fairly incoherent for frequencies above about 0.5 Hz.

It appears that the structures were exposed to high amplitudes of shaking and significant differential motion. These effects appear to be due to the geologic and topographic conditions of the interchange area. Amplitudes are such that they could have contributed to the separation of structures along hinge seats, which resulted in failure of the structures.

Acknowledgments

We thank the many Caltrans employees who allowed us access to the interchange at a difficult time. We also thank Paul Kasameyer, Dave McCallen, Lalliana Mualchin, and Joe Ueng for helpful discussions and Patrick Lewis and Jim Cullen for an extended field effort. Cynthia Hayek provided valuable input on geologic interpretations. Jennifer Hollfelder provided excellent technical assistance. Frank Marquez provided excellent graphics. This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract W-7405-Eng-48.

MR. BERGHOFF: GOOD AFTERNOON MR. CHAIRMAN, MEMBERS OF THE BOARD OF SUPERVISORS. MY NAME IS ARNIE BERGHOFF. MY ADDRESS IS 444 SOUTH FLOWER STREET, LOS ANGELES 90071. I'M THE DIRECTOR OF GOVERNMENT AND COMMUNITY AFFAIRS FOR BROWNING-FERRIS INDUSTRIES HERE IN SOUTHERN CALIFORNIA.

I WOULD LIKE TO VERY BRIEFLY MAKE THE PRESENTATION ON BEHALF OF MR. RON PFEIFER WHO'S OUR REGIONAL VICE PRESIDENT FOR OUR NEWLY-FORMED WESTERN REGION. MR. PFEIFER IS OUT OF TOWN TODAY AND HAS ASKED ME TO MAKE THIS BRIEF STATEMENT FOR HIM.

I APPRECIATE THIS OPPORTUNITY TO PRESENT THIS TESTIMONY, AND AS I INDICATED, I WILL BE QUITE BRIEF IN THE INTEREST OF TIME SINCE WE ARE ALL GETTING HUNGRY AND RUNNING QUITE LATE.

I WOULD LIKE TO RESPOND TO CONCERNS RAISED BY SOME REGARDING B.F.I.'S COMMITMENT TO ENVIRONMENTAL COMPLIANCE IN THE OPERATION LANDFILLS AND TO ENSURE THAT B.F.I. IS NOT ONLY A COMPETENT OPERATOR, BUT A COMPANY THAT STRIVES TO EXCEED AND NOT JUST MEET ENVIRONMENTAL RULES. B.F.I.'S OBSESSION, IF YOU WILL, WITH COMPLIANCE NOT ONLY APPLIES TO OUR LANDFILL OPERATIONS BUT TO ALL PARTS OF OUR VARIED WASTE BUSINESSES AS WELL.

I'M NOT GOING TO ADDRESS PARTICULAR QUESTIONS ON OUR OPERATION OF THE SUNSHINE CANYON LANDFILL. MR. WESTON HERE, AS HE INDICATED, WOULD BE HAPPY TO RESPOND. WE HAVE OTHER MEMBERS OF OUR COMPANY WHO COULD RESPOND TO THOSE.

ALSO, I WOULD LIKE TO POINT OUT THE EXTENSIVE

VOLUME OF THE RECORD ON THIS PROJECT, WHICH DOCUMENTS BOTH SIDES OF OPERATING HISTORY ISSUES. IT IS CLEAR TO ME, HOWEVER, THAT ALTHOUGH DIFFERING VIEWPOINTS WERE EXPRESSED ON THESE ISSUES, WE WERE NOT PERFECT AND THAT SOME MISTAKES WERE MADE. WE OBVIOUSLY CAN'T RECTIFY PAST MISTAKES, BUT I'M HERE TODAY TO COMMIT THAT B.F.I. WILL NOT ONLY MEET THE REQUIREMENTS OF THE VOLUMINOUS CONDITIONS CONTAINED IN THE CONDITIONAL USE PERMIT, BUT WILL STRIVE TO EXCEED ALL REQUIREMENTS.

B.F.I. RECOGNIZES THAT ITS ABILITY TO SURVIVE AND SUCCEED AS A BUSINESS DEPENDS IN LARGE PART, NOT JUST ON REGULATORY COMPLIANCE, BUT AGAIN ON EXCEEDING PUBLIC EXPECTATION REGARDING HEALTH AND SAFETY AND THE ENVIRONMENT IN EVERY ASPECT OF YOUR OPERATIONS.

WE ARE FIRMLY COMMITTED TO ENVIRONMENTAL EXCELLENCE. THIS COMMITMENT STARTS RIGHT AT THE TOP WITH OUR CHAIRMAN, BILL RUCKELSHAUS, AND IS SHARED AND REINFORCED AT EVERY LEVEL OF MANAGEMENT.

LET ME TAKE JUST A VERY BRIEF MOMENT TO DESCRIBE HOW B.F.I. HAS RESPONDED TO INCREASED CONCERNS ABOUT PROTECTING AND ENHANCING OUR ENVIRONMENT IN THE UNITED STATES. THIS CONCERN COMES FROM OUR SHAREHOLDERS, OUR EMPLOYEES, THE PUBLIC AT LARGE.

IN EARLY 1989, B.F.I. ESTABLISHED AN ENVIRONMENTAL POLICY COMMITTEE TO REVIEW EXISTING ENVIRONMENTAL COMPANY POLICIES AND TO DEVELOP NEW POLICIES FOR THE COMPANY. SINCE THEN, WE HAVE EXPANDED THE ROLE OF THIS COMMITTEE, OF WHICH RON PFEIFER IS A MEMBER, TO SERVE

AS A GUIDE FOR THE COMPANY IN DESIGNING, IMPLEMENTING, COMMUNICATING AND MONITORING PROGRAMS AIMED AT ACHIEVING CONTINUAL IMPROVEMENT IN THE ENVIRONMENTAL HEALTH AND SAFETY PERFORMANCE OF OUR COMPANY.

THE COUNCIL MEETS REGULARLY, AND A REPORT IS ISSUED THAT INDICATES ANY VIOLATIONS THAT WE HAVE THAT NOT ONLY SAYS WHAT A GREAT JOB WE ARE DOING BUT ALSO POINTS OUT VIOLATIONS WE HAVE IN AREAS THAT WE NEED TO IMPROVE.

EACH OF YOU HAVE BEEN DISTRIBUTED A COPY OF OUR LATEST REPORT. I'D LIKE TO POINT OUT THAT THE REPORT IS AIMED AT OUR GOAL OF ENVIRONMENTAL EXCELLENCE TO HAVE ZERO VIOLATIONS. LET ME REPEAT THAT. THAT IS, NO VIOLATIONS AT ALL. THAT IS OUR GOAL.

THE KEY TO B.F.I.'S ENVIRONMENTAL MANAGEMENT PROGRAM IS A SERIES OF HIGHLY STRUCTURED TRAINING PROGRAMS FOR ALL EMPLOYEES FROM THE TOP ALL THE WAY DOWN TO THE GENTLEMAN WHO WORKS, OR LADY WHO WORKS AT THE LANDFILL, AND THE UNIQUE COMPENSATION PROGRAM WHICH WAS OUTLINED IN THE REPORT THAT TIES THE MAJOR PORTION OF THE MANAGER'S ANNUAL PAY TO HIS OR HER ENVIRONMENTAL PERFORMANCE.

I WOULD LIKE TO CONCLUDE MY REMARKS BY READING OUR COMPANY'S MISSION STATEMENT, WHICH HANGS IN MY OFFICE AND THE FRONT OFFICE OF EVERY B.F.I. LOCATION IN THE COUNTRY.

"OUR MISSION IS TO PROVIDE
THE HIGHEST QUALITY WASTE COLLECTION,
TRANSPORTATION, PROCESSING, DISPOSAL
AND RELATED SERVICES TO BOTH PUBLIC AND

PRIVATE CUSTOMERS WORLDWIDE. WE WILL CARRY OUT THAT MISSION EFFICIENTLY, SAFELY AND IN AN ENVIRONMENTALLY RESPONSIBLE MANNER, WITH RESPECT TO THE ROLE OF GOVERNMENT IN PROTECTING THE PUBLIC INTEREST."

AGAIN, LET ME MAKE THIS CLEAR. THIS MISSION STATEMENT IS NOT JUST A PUBLIC RELATIONS PLOY. OUR ENVIRONMENTAL HEALTH AND SAFETY REPORT IS NOT JUST A PUBLIC RELATIONS PLOY. WE TAKE THE BUSINESS OF ENVIRONMENTAL COMPLIANCE IN OUR CORPORATION VERY, VERY SERIOUSLY.

THANK YOU VERY MUCH.

MR. EDELMAN: OKAY. THANK YOU, AND NOW WE ARE GOING TO RECESS UNTIL 2:15, AND EVERYBODY WHO WANTED TO BE HEARD THIS MORNING, IF YOU WOULD LIKE TO BE HERE AT 2:15, WE WILL BE HAPPY TO HEAR THEM.

WE WILL STAND IN RECESS NOW UNTIL 2:15.

(LUNCH RECESS)

MR. EDELMAN: GOOD AFTERNOON.

OKAY. WE WILL CONTINUE THE HEARING THAT RECESSED TODAY.

MR. ANTONOVICH?

MR. ANTONOVICH: MR. CHAIRMAN, CAN WE JUST CALL ROSEMARY WOODLOCK UP FOR 60 SECONDS. SHE HAS A PROPOSAL STATEMENT TO MAKE RELATIVE TO NEGOTIATIONS ON REACHING SETTLEMENT.

MS. WOODLOCK: THANK YOU, MR. ANTONOVICH.

MR. CHAIRMAN, WE ATTEMPTED ALL DURING LUNCH

BFI Sub Agrees to $5M+ Settlement Of CWA Conspiracy-Disposal Case

BFI Services Group Inc., has agreed to pay a $3 million fine and $2.14 million in cleanup contributions to settle Justice Department charges that the company improperly collected, stored and disposed of raw sewage, grease and sludge in the Philadelphia area.

BFI Services, a subsidiary of Houston-based Browning Ferris Industries Inc., agreed to plead guilty to one count of violating the Clean Water Act and one count of conspiring to violate the CWA, according to the Justice Department.

POTWs To Receive $642K

The proposed settlement also requires restitution payments totaling $642,311 to four of the publicly owned treatment works affected by the alleged violations. Three of the POTWs are in Aston, Bridgeport, and Hatfield, Pa. The fourth is in New Castle, Del. Browning Ferris Industries Inc. would not face prosecution for infractions at those facilities.

DoJ alleges BFI Services illegally dumped wastes on 1,577 occasions from 1989 to 1992. Wastewater from these 4,600 waste loads allegedly contained prohibited treatment sludges and/or grease. In many instances, the company gave the POTWs false samples of waste slated for disposal, DoJ says. Other times, the firm allegedly gave POTWs unrepresentative samples containing a blend of raw sewage and other wastes to make it suitable for disposal.

DoJ also charged several past and present BFI Services employees in the case, including Robert Atkinson, the ex-president. He is charged with one count of violating the CWA and if convicted faces a maximum $100,000 fine and up to a year in jail.

INDICTMENT PUZZLES BFI OFFICIALS

John Russell

PHILADELPHIA -- A federal grand jury has indicted a defunct unit of Browning-Ferris Industries Inc. and six employees on charges of illegally dumping more than 4,500 loads of sewage at five wastewater treatment plants.

The actions defrauded the municipal plants in Philadelphia and New Castle, Del., of about $1.3 million, said the U.S. Attorney's office in Philadelphia.

BFI officials expressed surprise with the indictment, saying they discovered the illegal activity on their own four years ago, fired those responsible, corrected the situation and reported everything to the FBI and other government agencies.

In addition, BFI paid Philadelphia $1.6 million in restitution and an unspecified amount to New Castle in 1992. BFI managed to get a new permit to use the treatment plants within two months, officials said.

"We took all the proper steps," said Philip S. Angell, BFI's assistant to the chairman. "That was 41/2 years ago. We thought everything was settled."

The grand jury returned a 23-count indictment Nov. 21 against BFI Services Group Inc. and employees Robert Atkinson, Robert Douglass, Jeffrey Turbedsky, Gary Rice, Michael Malatesta and Kevin Cornell.

The charges include violations of the Clean Water Act, conspiracy, mail fraud and aiding and abetting.

Of the employees named, only Turbedsky, a BFI accountant, remains with the firm and has maintained his innocence. BFI said it fired three others, and two had resigned.

BFI shut down the operation and reassigned employees to other duties.

The Houston-based waste company had acquired the unit in 1989 as Gary Rice & Sons, plus two other small companies that were tucked into the operation.

The unit carried out a wide range of portable waste services, including portable toilets and street sweeping.

BFI said it discovered the improper activities shortly after Rice left the operation in 1992. A new district manager took over and was told Philadelphia had rejected a load of BFI sewage at a city treatment plant.

"That set off alarm bells," BFI spokesman Peter Block said. "The new district manager sent the news up the chain of command, and we launched an investigation."

The investigation showed that unit employees had been mixing wastewater sludge and grease with raw sewage, presenting it to the wastewater plant as sewage, which is cheaper to treat than the other substances.

Offending incinerator removed BFI admitted tampering with monitoring device

JOHN ECKBERG
The Cincinnati Enquirer

A Butler County medical waste incinerator that authorities thought operated illegally from 1993 to December 1994 is being dismantled and trucked to other facilities by owner Browning-Ferris Industries.

BFI officials admitted to Union Township officials last month that three monitoring devices were tampered with or bypassed at the plant at 9899 Charter Park Drive in West Chester.

After the admissions, the plant was closed. Operations at the plant are the subject of an investigation by the Ohio Environmental Protection Agency.

The dismantling operation that started Thursday was welcome news to township trustee Catherine Stoker, a long-time critic of the plant.

"The bottom line is they're leaving and I'm pleased," she said. "They appear to be in a great big hurry. This is a nice Christmas present for the community."

Steven H. White, vice president of governmental affairs for BFI, said parts from the plant will be used at other company facilities.

BFI owns 32 medical waste incinerators or autoclave waste sterilizers in the United States. Both systems dispose of medical waste. The company is based in Houston, Texas.

There was no ambiguity with the initiative Thursday, White said.

"It's being taken apart," White said. "We've closed the incinerator permanently. It represents a couple hundred-thousand-dollar investment."

Portions of the plant that are being removed are not connected to issues or violations reported by the company, White said.

Company officials plan to immediately remove a unit used to wash tubs that held waste material and a waste water treatment device.

"It will take several months before everything is removed that we want to remove for salvage," White said.

The company's admissions of wrongdoing followed a lawsuit filed in Butler County Common Pleas Court against BFI in May by a former operations manager, Bill Little.

He claimed in that action that poor maintenance meant the plant operated safely only two to three days a week. He also claimed the company over-billed clients. The case is pending before Judge Anthony Valen, and a trial is tentatively set for March 4, 1996.

The plant was permitted to burn up to 1,500 pounds per hour of infectious waste and has operated since September 1991. It incinerated about 900,000 pounds per month.

Devices that were bypassed include:

A lock on the incinerator door to prevent it from being opened if the temperature in the incinerator dipped below standards.

A combustion temperature recorder that keeps a continuous record of heat in the incinerator.

The continuous environmental emission monitoring device, which measures the amount of environmental pollutants that leave the plant through the stack.

Those instruments will be left on site "until we've been told by appropriate officials that they have gotten whatever information they need," White said.

Environmental activists in West Chester have long claimed that the plant was operating without regard for state pollution regulations.

Stoker said if the company plans to eventually vacate the site, she expected any left-over contamination to be removed.

Waste facility closed

Post staff report

The Ohio Environmental Protection Agency is closing down an infectious-waste incinerator in West Chester after its operator last week notified the agency of problems at the plant.

Ohio EPA Director Donald Schregardus Friday said he would keep the incinerator, which is currently shut down for routine maintenance, closed until the accuracy of its monitoring equipment has been independently verified.

Browning Ferris Industries said the company had violated Ohio environmental laws in 1993 and 1994 in its temperature-monitoring equipment and reporting. Schregardus said based on what Ohio EPA has been told, it appears the company falsified operating records.

The Ohio EPA and Ohio Attorney General's Office are investigating possible criminal violations. BFI is expected to provide a written report on the incidents next week.

The incinerator is in Union Township. BFI officials could not be reached for comment.

FLA. OFFICIALS RAID BFI SITE: STATE AND COUNTY AGENCIES ALLEGE FACILITY ILLEGALLY HANDLED CONSTRUCTION AND DEMOLITION DEBRIS, OTHER SCRAP MATERIAL

Steve Daniels

WEST PALM BEACH, FLA. -- Browning-Ferris Industries Inc. is accused of illegally operating a construction and demolition debris transfer station at a site permitted only for yard-waste processing in the small Florida farming town of Pahokee.

Investigators with the Palm Beach County (Fla.) Sheriff's Office and the state's Department of Environmental Protection found household trash, C&D debris, used oil and other materials when they raided the operation Jan. 29, said James Pearsall, an environmental investigator with the Sheriff's Office.

Site manager Robert Edward Lee was charged with three misdemeanor violations of state environmental rules.

The company, the second largest waste firm in North America, will face similar charges, Pearsall said.

"They know what it is they're supposed to be doing," he said.

Each of the charges carries potential penalties of six months in jail and a $10,000 fine.

At the site, located next to a closed ash landfill owned by the town of Pahokee, BFI processed yard waste under contract with the town.

BFI's permit confines activity at the site to mulching landscape waste, officials said.

But BFI also was using the property to sort and transfer C&D debris and other materials, Pearsall said.

Investigators found common trash, tires, used oil, car batteries, old paint and mercury vapor light tubes during their inspection, the Sheriff"s Office official said.

All the materials were on the ground, although there is a building on site, he said.

Investigators found several cars belonging to workers parked inside, Pearsall said.

The unpermitted transfer operations had been occurring for at least the past few months, according to the investigator.

"It was a well-established operation," Pearsall said.

A BFI spokeswoman said the company had begun an internal investigation and was preparing to meet with state authorities soon.

"We will flat get to the bottom of it," she said. "Until we get to the bottom of it, we are stopping operations [in Pahokee]."

If the allegations prove true, culpable BFI personnel will be held accountable, she said.

The company has no tolerance for violating permit conditions, the spokeswoman said.

Pahokee officials were unaware that materials other than yard waste were being handled at the site, Pearsall said.

A 15-foot berm BFI constructed around the property obscured a clear view of the activities there, the investigator said.

The company is not lacking in area facilities to manage C&D debris. BFI runs a C&D operation in West Palm Beach, about 37 miles away, Pearsall said.

Alleged Illegal Dumping Prompts FBI Raid at Plant; D.C. Facility Handles Medical Waste Disposal

Vernon Loeb; Toni Locy
Washington Post Staff Writers

Dozens of FBI agents raided a medical waste disposal plant in Northeast Washington yesterday morning and carted off boxes of documents as part of an investigation into alleged illegal dumping of biomedical waste.

The agents, wearing surgical masks and yellow protective clothing, shut down the facility, which is operated by the nationwide waste disposal firm Browning-Ferris Industries Inc. Investigators conducted a day-long search of the plant, and they ordered crews from the D.C. Water and Sewer Utility Administration to pump dye into sewer mains that carry water runoff to track its path.

Susan Lloyd, a spokeswoman for the FBI's Washington field office, described the raid as "an environmental matter" and said agents would assemble all evidence seized before determining whether arrests would be made.

Philip S. Angell, a senior official at Browning-Ferris, said last night that the company was mystified by the large-scale federal operation and that all medical waste coming into the facility -- including "pathological waste," such as body parts -- remains sealed at all times.

Angell also said that FBI agents interviewed about a dozen Browning-Ferris employees at the facility without the presence of company attorneys. "To the extent that we're upset, it's because we don't know what's going on or why," the official said.

The FBI turned the facility back over to Browning-Ferris at 5:15 p.m. and walked management officials through the plant without requiring anyone to wear protective clothing, according to Arthur J. Schultz, a spokesman for Browning-Ferris who was present. Schultz said FBI officials told the company that it was free to open the plant for business today.

The plant, at Fairview Street and New York Avenue NE, is a major transshipment point for medical waste from area hospitals and has been in operation for about four years. Angell said that all medical waste that arrives by truck -- syringes, surgical clothing and the like -- remains sealed in plastic bags and is placed in two large autoclaves that sterilize the waste by steam-heating it to 300 degrees. Once sterilized, the waste is ground up and disposed of in regular landfills, he said.

Angell said that trucks also ship sealed containers containing pathological waste -- human flesh, blood, body parts and other surgical debris -- to the plant. But those sealed containers, he said, are immediately placed on other trucks and then shipped to a special incinerator in Baltimore.

"They come into the facility in sealed containers and go out of that facility in sealed containers," Angell said. "There is no processing of body parts at that facility."

Angell said the plant passed an inspection in the fall by the federal Occupational Safety and Health Administration.

"Inspectors come into that plant all the time," Angell said.

Cheryl Byrne, an OSHA spokeswoman, said the FBI alerted the agency about the raid yesterday, as is standard procedure whenever law enforcement officials suspect a potentially dangerous situation for employees of a particular company.

"We will indeed follow up on the FBI referral to make sure the employees are not in danger," Byrne said.

D.C. Council member Harry Thomas Sr. (D-Ward 5), chairman of the council's Public Works Committee, said residents who live near the facility started calling his office as soon as the FBI arrived at the plant yesterday morning. Thomas's committee has oversight jurisdiction over all waste facilities in the District.

"About 20 cars came up there between 8:30 and 9, pulled in the place and closed it down," Thomas said.

Staff writers Marcia Davis, Howard Schneider, Cindy Skrzycki and Frank Swoboda contributed to this report.

Eden Prairie wins battle over landfill

Laurie Blake; Staff Writer

Saying that controversy over a suppressed report has damaged its credibility, Woodlake Sanitary Service Inc. decided Tuesday to end its efforts to reopen and expand the Flying Cloud Landfill in Eden Prairie.

The city has fought the proposed expansion with attorneys, public relations experts and citizen resolve. It declared a community victory, announcing the news in its schools and filling trash cans with bottles of champagne for a City Hall celebration.

"It's a great victory for the people and a wonderful victory for the environment," said Jerri Coller, who has led the Homeward Hills neighborhood in its fight against the expansion.

"I was just so concerned that my children were going to be at risk and the children of all my friends," she said. "I felt like a mother lion. I wasn't going to let anything happen to my babies."

City Attorney Ric Rosow said, "We just feel tremendous elation that much of our struggle has been vindicated and we succeeded in preventing what could have had adverse environmental and health consequences for the citizens of Eden Prairie. When I read the notice of withdrawal I had tears in my eyes I was so happy."

The Flying Cloud Landfill has been closed since April 1988, when the Minnesota Pollution Control Agency (MPCA) learned of methane gas concentrations along its eastern boundary. Woodlake, a subsidiary of Browning Ferris Industries, sought state approval to reopen the landfill and double its size. Browning Ferris is one of the nation's largest waste-disposal firms.

Last month, however, Woodlake admitted that it had suppressed for more than 1 1/2 years reports showing potentially explosive methane gas in the landfill along its south bluff area and garbage buried beyond the area permitted by the state.

That undermined the company's argument that it could be trusted to expand the landfill safely and called into question other information it had submitted in the case.

"The damage to our credibility as a result of this controversy makes continuing impossible," Woodlake President Stephen Benton said yesterday. "We are also reluctant to continue without support for this project from Eden Prairie and the larger Twin Cities community," he said.

"There really is nothing more important to us than credibility," Benton said. "There has to be confidence in what we are doing because the issues are tremendous. Unfortunately we hurt ourselves." He said he wants the public to treat the decision to withdraw as a gesture that will help rebuild trust in the company.

It announced its decision in a letter to the state administrative law judge who was holding proceedings on the proposed expansion. The expansion would have provided Woodlake and Browning-Ferris with at least $150 million in revenues from the dump fees paid by garbage haulers. Benton said Woodlake will concentrate on closing the landfill and siphoning off the methane, which is created by decomposing garbage. "We see it as an opportunity to be as open as possible with the community about what we are doing," he said. "We will be doing everything we can to assure that there are no threats to the public health or to the environment."

Cathy Kennedy, a vice president of Mona, Meyer and McGrath, Eden Prairie's public relations consultant on the landfill issue; said the city will be extremely interested in how the closing is handled.

Residents are concerned about what was dumped there, about ground water contamination and about methane gas concentrations, she said.

Benton said that eventually the site in south central Eden Prairie will be put to another use, but that that will be years from now and that the company has not yet decided what the use will be.

In the meantime, Benton said, the company will start looking for another site that would be suitable for a landfill. "We are planning to operate here and we want to operate responsibly, but we will be actively pursuing our business," he said.

Grant Merritt, a lawyer who represented the Homeward Hills residents, said he hopes the case will help end what he called the stranglehold that Browning Ferris has on the waste disposal industry in Minnesota. Woodlake's other operations include landfills in Medina and Inver Grove Heights.

Merritt, former head of the MPCA, said he disputed the company's statement that one employee, Rollin Smith, acted alone in deciding to suppress reports about the methane gas. Smith retired as vice president of Woodlake on July 27. Had the case

continued, Merritt said, he had intended to investigate that further.

Smith has said he retired for medical reasons and denied being forced out of the company because of any suppression of reports.

Rosow, the city attorney, said Eden Prairie residents suspected all along that there was more to the landfill issue than Woodlake was admitting, and the city's lawyer had tried throughout to prove that Woodlake was not fit to expand the landfill. Fitness is a showing of whether a company can be trusted to observe all governing rules and regulations, he said.

Once it became known that at least one employee apparently had acted dishonestly in concealing a report about the methane gas, "It sealed their fate on the fitness issue," Rosow said.

Coller went to City Hall yesterday where she learned of the company's decision.

"When it finally hit home I cried. I fell apart. They gave me tissues and a chair," she said.

Although the landfill fight took time away from her family, Coller said, "I look at my children and what I've taught them and I know they know to fight for what is right and that if you fight long enough you win."

John Rafferty, solid waste division chief for the Metropolitan Council, said the loss of the Flying Cloud landfill will have little effect on the overall garbage disposal situation in the Twin Cities area.

The Twin Cities has enough landfill space to last until 1995. The options are to dig more of them, expand existing ones or take waste to sites outside the metropolitan area.

Eight sites for landfills are under consideration, four in Hennepin County , three in Anoka County and one in Washington County.

BFI can't buy a good reputation

Susan Varlamoff; Mary Anderson

It never ceases to amaze us what money can buy. A good example is the series of ads run by Browning Ferris Industries (BFI) which began with the headline, "Browning Ferris Industries in the forefront of cleaning up America." The obvious intent of these ads is to brainwash the citizens of Hennepin County into thinking that BFI is a respectable company concerned about cleaning up the environment.

As residents living next to the Flying Cloud Landfill, which is owned and run by BFI, we have had firsthand experience with BFI's alleged concern for our environment. BFI has a proven record of disregard for the very laws designed to protect our environment. Its infractions range from the sublime to the ridiculous. For example:

Illegal disposal of ice cream waste in Alabama. BFI was fined $15,000.

Price fixing in Ohio. BFI was fined $1 million.

1,700 violations in Louisiana. BFI was fined $2.5 million.

Closer to home, at the Flying Cloud Landfill, the list of infractions goes on. In the recent ads, BFI boasted of "sound management practices and environmental protection." We'd like to respond directly to this claim.

First, the Flying Cloud Landfill has been so "well managed" that it now ranks on the state superfund list. Past landfill employees report that there was little or no monitoring control of the garbage dumped in the landfill. BFI ran the facility 24 hours a day and seven days a week in violation of permit regulations. Hardly a record to be proud of.

The "sound management" practice of BFI also allowed the Flying Cloud Landfill to mysteriously double in size without authorization, once again violating permit regulations. BFI then had the audacity to apply to the government to double its already unauthorized double capacity.

Where was BFI's concern for the environment in 1985 when it knowingly withheld information concerning contamination in the landfill until it received approval for expansion from the Metropolitan Council? Does this track record exemplify a company with sound management practices and environmental protection?

Today Eden Prairie must live with the contaminated mess created by BFI. The sand and gravel pit in which BFI dumps its garbage has no barrier to prevent pollutants from quickly entering the ground water. The aquifer from which we obtain our drinking water is contaminated. This contaminated water is flowing toward the Minnesota River and the biggest urban wildlife refuge in the United States. The bluff on which the landfill is situated is unstable and is falling off in chunks. The methane gas contamination is out of control. And surrounding this polluted mess are the homes of thousands of innocent citizens.

Because of pressure from the city of Eden Prairie, concerned citizens and the Pollution Control Agency, BFI is being forced to clean up the landfill. But there is no conclusive evidence that the engineered bells and whistles BFI proposes to use for cleanup will mitigate the present contamination. A recent congressional study of 100 superfund sites questions whether we are cleaning up the mess or messing up the cleanup.

Thomas Jefferson once said that "when things get so far wrong we can rely on the people when well informed to set things right." That's what the city and citizens of Eden Prairie are doing. We certainly will not give BFI the opportunity to contaminate any more of Eden Prairie.

We have beaten BFI in the Legislature, shut down its dump and taken away at least 15 percent of its business in Eden Prairie. BFI can continue to spend millions of dollars on advertisements, public relations, lawyers and experts, but it can never buy the truth. BFI has taken big risks with the people and the environment of Eden Prairie simply to make big money. And that's unconscionable. Susan Varlamoff and Mary Anderson, Eden Prairie. Neighbors of the Flying Cloud Landfill.

NEWS

BFI faces big fine over site at N.O.

FRED KALMBACH

Browning-Ferris Industries, an international waste-disposal company with five landfills in Louisiana, faces a $400,000 fine for a string of unsanitary practices at its site near New Orleans.

State Department of Environmental Quality officials first reported violations at BFI's Crescent Acres landfill in 1986, and levied a $10,000 fine after follow-up investigations found the company continued to break the law, according to DEQ records. Subsequent investigations turned up similar problems in 1988, prompting the $400,000 penalty, according to DEQ records.

BFI buries solid municipal, commercial and medical wastes at the landfill, which primarily serves the New Orleans area. The site is operating on a temporary permit pending DEQ's decision on the number and location of landfills needed to handle solid waste statewide.

The most serious violations at Crescent Acres involved acres of garbage and other waste at the site left uncovered and open to rats, flies and birds, according to Paul Miller, head of the Department of Environmental Quality's solid waste enforcement office.

"There was a very severe situation at the site," said Miller. "The sheer area of uncovered waste and ... the history of problems there led to the high fine."

BFI spokesman Peter Block said that company officials have not decided whether to appeal the fine, but added that the problems have been corrected.

"We would like (DEQ) to have a sense of comfort that we are doing the right things now," he said. DEQ inspections conducted after the violations noted in 1988 showed that BFI was operating properly.

State law requires landfill operators to cover exposed waste with six inches of soil to contain the garbage and to protect it from scavengers and insects.

BFI has failed to properly cover landfills at other sites _ as have other waste management companies _ but not to the degree found at Crescent Acres, Miller said. After violations at other landfills, BFI quickly complied with the regulations, he noted.

Since 1986, DEQ inspectors found that besides failing to properly cover the landfill, BFI illegally disposed of infectious medical waste, failed to keep litter from blowing off the site, dumped waste in standing water, and failed to pile waste in the smallest area practical. BFI also allowed contaminated liquid to seep from the landfill and failed to properly maintain wells that monitor contamination leaking into underground water supplies, according to DEQ records.

During the 1986 inspections, state officials noted that bloody bandages, hyperdermic needles and blood bags had been mixed in with other wastes, records show.

The fine this week was stiff because "the facility has a history of serious violations which are corrected but then reoccur," the penalty notice states. "While the operators express a willingness to cooperate, the fact remains that the same serious violations occur over and over again," the notice states.

BFI owns other landfills in Monroe, Lake Charles, Ascension Parish and in Jefferson Parish, and operates the Shreveport city dump under contract. Plans to expand the landfill in Lake Charles have been thwarted by the Calcasieu Parish Police Jury, which rezoned land adjacent to the existing site to preclude dumping.

BFI is also cleaning up toxic contamination that spread from an old hazardous waste dump owned by one of its subsidiaries, CECOS International, in Calcasieu Parish. The state Attorney General's Office has sued BFI and other companies for allegedly contaminating state waters with cancer-causing chemicals.

State officials have posted signs along a half-mile stretch of Olsen Bayou in Calcasieu Parish which warn that the bottom of the waterway is contaminated with toxic waste from several dumps, including the one owned by BFI.

Protesters raise stink over landfill

AP

ARABI (AP) _ About 20 residents of this New Orleans suburb marched and waved handmade signs as garbage trucks rolled in and out of Crescent Acres, the only solid waste landfill in New Orleans.

The protesters want the state Department of Environmental Quality to turn down requests that would let the dump stay open until 1993. It currently operates with an interim permit.

"Garbage stinks," said 3-year-old Kenneth Anthony.

With a surgical mask hanging below his chin, Kenneth was cradled in his grandmother's arms outside the main entrance of the landfill Tuesday.

The dump was the site of one of two protests organized by residents who say odors from the landfill force them indoors and decrease the value of their property.

Kenneth's grandmother, Myrtle Anthony, said she took to the streets because she and others have run into a bureaucratic wall trying to rid their neighborhood of the stench.

The landfill gets about 500 tons of New Orleans trash a day and all of St. Bernard Parish's trash.

About a dozen Arabi residents also protested Tuesday outside the Police Jury Complex in Chalmette.

"They want to attack (the odor problem) politically as well as legally," said Val Exnicios, a New Orleans lawyer.

Exnicios' firm is urging many Arabi residents to join a lawsuit against Browning-Ferris Inc., landfill operators, and the New Orleans Sewerage & Water Board, which operates the nearby East Bank Sewerage Treatment Plant.

"You can't bring an odor into a courtroom and say, "Here, jury: Smell this.' What you can do is bring 200 people into court and say, "Jury _ this is damaging our property,' " he said.

About 15 residents already have joined a suit filed by two families against BFI and the S&WB. The suit charges that odors from both facilities deny residents the right to enjoy their personal property.

Both BFI and the S&WB have denied that their facilities are responsible for the smell.

OWNERS END FIGHT TO REOPEN LANDFILL

KAREN TURNI St. Bernard/Plaquemines bureau

The owners of the Crescent Acres landfill threw in the towel Wednesday and dropped two appeals to continue accepting garbage.

Browning-Ferris Industries was fighting two separate rulings by the state Department of Environmental Quality, one of which forced the landfill to stop taking garbage March 31.

"We looked at all the costs involved and decided that it would be much wiser to go ahead and look for some new solutions in the New Orleans area" rather than pursue the appeals, BFI spokeswoman Karla Swacker said. "New landfill sites, recycling technologies and waste-to-energy are three viable options."

The company had wanted to continue taking garbage for a few more months to improve the contour of the 46-foot garbage heap to reduce erosion. The company appealed a ruling that prohibited that plan.

BFI also had appealed a January decision by DEQ rejecting the company's request to continue operating the landfill for six more years. That matter was scheduled to be heard by a DEQ administrative law judge this month.

"Without the support of the individual parishes, Crescent Acres was not a viable solution. We would much rather work with local government," Swacker said.

Arabi residents have long complained of odors and noise from the landfill, which straddles the New Orleans-St. Bernard border. The St. Bernard Parish Council and School Board also have supported closing the landfill.

Arabi resident John Palmer, an outspoken critic of Crescent Acres, said he was glad to hear BFI dropped the appeals, but he remained concerned about the site. "We've got a facility back there that is an old landfill and we still don't know what's underneath it. The environmental problems and the future health problems it could create are now a major concern."

DEQ Secretary Kai Midboe said BFI and DEQ are still negotiating plans for the site's closure and long-term maintenance.

"Obviously we're pleased that they have dropped their appeals," Midboe said. "We have wanted them to close in accordance with their permit and this will bring that about."

Sierra Club files complaint over BFI landfill with state

Jesse Clements Express-News Staff Writer

The Lone Star Chapter of the Sierra Club has filed a complaint with the Texas Natural Resource Conservation Commission, claiming the agency failed to issue nuisance-violation notices concerning operations at the BFI landfill on Tessman Road.

A copy of the complaint was provided to the San Antonio Express-News after an article in Sunday's Metro section laid out allegations by nearby neighbors and actions by BFI to rectify the problems.

An application by BFI is pending before the commission to raise the altitude of a section of the dump nearest the homes of residents from 710 feet above sea level to 756 feet.

Neil J. Carman, the Clean Air Program Director of the Sierra chapter, charged the commission had been apprised of numerous complaints by residents near the landfill. "But next to nothing was ever done to correct these problems," he wrote to the agency's executive director, Dan Pearson.

However, an agency spokesman, Terry Hadley, said Carman's letter of complaint, dated Jan. 25, provided no new allegations.

"In fact, BFI was cited (by TNRCC) Jan. 9 for unauthorized discharge of water into Martinez Creek," he said.

But Carman wrote:

"Even though the Tessman Road Landfill is classified as a minor source for air pollution and there has been no requirement for the TNRCC to routinely investigate such minor facilities, we have serious concerns about environmental protection for all communities despite living next to such dirty, dusty, stinky, nasty sites."

Carman castigated the state agency for allegedly failing to enforce the provisions of the Texas Clean Air Act not only at the Tessman Road dump, but also at dumps in Ferris and Fort Bend County.

He specified air contaminants such as garbage and sludge odors, dust and blowing debris.

Noting his previous employment as a state air pollution inspector, Carman called on TNRCC to develop a list of all landfills poorly sited near residential areas and then give more attention to improving air quality.

"Tracking of such landfills needs major improvement statewide," his letter concluded.

Hadley said his agency was currently reviewing a number of videotapes taken and provided by neighbors who were complaining of the dump's conditions.

"But what we are seeing is dust and blowing debris confined to the landfill itself - not on others' property," he said.

Hadley said the commission has addressed all the complaints over the past few years.

Asked if BFI had been fined for the citation, Hadley said the purpose of such citations is to bring violators into compliance, rather than as a punitive measure.

"There will be no future penalties (as a result of the citation)," he added.

But Joe Irizarry, divisional sales manager for BFI, disputed that TNRCC even issued a citation.

He said the agency had simply warned the company that it should notify TNRCC anytime anything was pumped into the creek.

"What this was," Irizarry said, "was accumulated rainwater that was not even on the landfill premises. TNRCC said to notify them in advance next time in case complaints were made."

He said BFI welcomes the many visits of regulators or people with complaints.

"We certainly don't mind additional scrutiny," he added.

A public hearing on the expansion permit will be scheduled by the commission during the last two weeks in March, a spokesman said last week.

Buyout blues Martinez mulls future

Joseph Barrios
Express-News Staff Writer

Sundays in Martinez have always been the favorite for Mike Jaksik.

The 72-year old remembers how families would go to church, then meet afterward for coffee at the general store at the corner of Farm Roads 1516 and 1346.

Nowadays, Sundays offer Jaksik relief from the giant dump trucks that six days per week haul trash into the landfill near his property, and from the flocks of buzzards that fly over his house to feed off carrion.

"This used to be a real quiet community. We didn't have much traffic," said Jaksik, a lifelong Martinez resident. "At 5 o'clock every morning, when those trucks round the corner, they give it the throttle. That wakes me up every damn morning."

Residents in the tiny Southeast Bexar County community have been fighting the Browning-Ferris Industries landfill since 1981, when plans to build it first surfaced.

With the announcement last month that about a dozen homeowners along Farm Road 1516 plan to settle a lawsuit against BFI and sell their houses, remaining residents doubt Martinez has a future. Longtime residents remember when Martinez was a close-knit community, surrounded by rolling hills dotted with trees and farm land. Area farmers grew cotton or corn. Most people shopped at the general store.

"My children are fifth-generation raised on this land," said W.L. Shodrok, whose great grandfather bought several acres of land in the 1890s, southeast of the main intersection. "My family has been in Martinez for a long time. It was a really wonderful place to be,"

Shodrok, who grew up just south of the intersection of Farm Roads 1516 and 1346, said the landfill's dominance over Martinez "spread like cancer" as BFI purchased land next to homeowners.

"They couldn't sell the land to anybody but BFI. Then the landfill would spread out," Shodrok said. "Now they're buying those homes down on 1516. Pretty soon, no more Martinez."

Shodrok and Jaksik pointed to what they said are the most common complaints about the dump - nauseating fumes travelling for miles into people's homes, and garbage trucks spreading mud on the road.

Aside from the purchase of homes along Farm Road 1516, BFI is negotiating with a dozen or so other residents to get them to agree to the dump's expansion and stop thier public protests, said Donna Kolar, BFI general counsel.

Kolar said she does not believe the buyout will bring about the end of Martinez.

"I don't see why the community would disappear. People like the community," Kolar said.

But David Johnson, a history professor at the University of Texas at San Antonio, said residents have legitimate reasons to worry about their community disappearing.

"It's a common occurence: the conflict between a small community's history and a larger community now impinging on that community's lifestyle," Johnson said. "Here, it sounds like San Antonio is the larger community."

Bob Schneider, 74, owns 26 acres of land in Martinez. He refused an $8,000 settlement offer from BFI.

"I lived on this land before they ever started the dump," Schneider said. "It's a nice quiet community. There's very little crime, if any.

"I don't blame them for moving with that dump being across the street with all the buzzards and rodents," Schneider said of the homeowners along 1516.

Schneider believes BFI is only concerned with getting the land they want, not with residents' well- being.

"I guess they figure we're going to die pretty soon and they don't have to worry about us," Schneider said.

Meanwhile, Jaksik said he is trying to negotiate with BFI and get a "fair" payment for the devaluation of his land.

Jaksik said that until he moves away or dies, he will continue to enjoy Sunday mornings, when no garbage trucks roll into the landfill to dump their hauls.

"Sunday morning is a day of peace," Jaksik said. "It's just a

Group digs in to fight landfill/Legal efforts aimed at closing BFI waste site at Sinton

BILL DAWSON, Houston Chronicle Environment Writer Staff

A citizens' group at Sinton, near Corpus Christi, has launched a multi-part legal attack to shut down a landfill run by Houston-based Browning-Ferris Industries.

The landfill, originally designed for municipal solid waste, now has been authorized by the state to receive nonhazardous industrial waste, as well as municipal waste.

A group called Victims of Toxic Exposure, saying it represents most homeowners near the landfill, contends the facility has been improperly receiving hazardous waste.

The organization also is alleging a number of health problems stems from the landfill's operation.

""The chemicals coming from the landfill choke us and make us very sick,'' member Elsia Muniz said in an statement released by the group.

The organization has filed three legal documents in its campaign against the landfill, Austin attorney Rick Lowerre said.

They are a lawsuit in state court in Austin to close the facility, a notice of intent to sue BFI in federal court, and a petition asking the Texas Natural Resource Conservation Commission to revoke the company's state permit for the landfill.

BFI spokesman Peter Block said the landfill has been operated ""within permit requirements, other regulations and all applicable restrictions."

Among other allegations, the citizens' group charges the landfill contaminated groundwater, but Block said company officials are confident that claim is not accurate.

The air pollution incident that Muniz mentioned was confirmed, however, by Linda Fernandez, a spokeswoman for the state environmental commission.

A notice of violation was placed in BFI's file in January for ""nuisance conditions'' that occurred at the landfill when fumes were produced by Exxon refinery wastes received at the Sinton facility.

The wastes in question did not qualify as ""hazardous,'' and BFI has agreed to reroute future deliveries to avoid air pollution problems, Fernandez said, adding that the Natural Resource Conservation Commission has no evidence that the landfill has received waste that legally qualifies as ""hazardous."

Apart from the allegations pertaining specifically to the BFI facility, Lowerre said the citizens want the commission to reassess policies under which it allows municipal waste landfills to receive industrial waste so citizens will be notified and given a chance to comment.

STATE

South Texas residents join to fight BFI/Waste firm argues landfill will be safe

JAMES PINKERTON
Staff

DONNA -- A crude, hand-lettered sign declares ""El Agua es Vida."

The Spanish words -- ""Water is Life'' -- are the battle cry of thousands of Rio Grande Valley residents opposing a proposed Browning-Ferris Industries Inc. landfill.

They fear the dump could contaminate the drinking water piped to 12,300 households.

BFI's proposed landfill would be 1,320 feet from the reservoir that holds the residents' only water supply.

Since obtaining a permit in 1988, efforts by the Houston-based corporation to develop the landfill have been challenged in court; company lawyers have responded with personal lawsuits against Valley elected officials who have blocked the project.

BFI, with annual revenues of $3.2 billion, operates 100 landfills in the United States and eight other countries.

Company officials insist the landfill design is safe, and that opposition inevitably follows a landfill -- no matter where the location.

And the Valley location, they argue, meets all of BFI's groundwater and land use criteria.

Opposition comes from the cities of Alamo, Donna and Weslaco, the Donna school district, the Hidalgo County Farm Bureau, the Sierra Club, McAllen Mayor Othal Brand, the Audubon Society, a group of small business owners and 3,500 residents who have signed a petition.

""It's mostly that there are so many unknowns, you don't know what the potential is,'' says Lori Castaneda, a member of Citizens Against Landfill Location. ""You've seen so many landfills where there have been problems we just don't know what could happen."

Castaneda, husband Fidel and their five children live on five acres her husband's family bought 35 years ago in the Valley's Winter Garden area. Her mother-in-law lives in a house on the same property.

They don't relish the sight of a 44-foot-tall landfill rising on land across the highway from their home.

But they are more concerned about possible contamination of their drinking water because the 135-acre landfill tract is only a quarter-mile from the reservoir that supplies water to more than 55,000 residents.

Bill Crier, a spokesman for Gov. Ann Richards, said the governor is aware of the dispute.

""The governor has, in fact, agreed with the people and shares their concerns,'' he said. ""She has assured them if it is approved by the court system -- which of course she has no control over -- she will make sure the thing is built properly so the water is absolutely safe.

""This was approved 18 months ago by the Health Department before she was elected so there's not much she can do about it."

The concerns of area residents are understandable.

The North Alamo Water Supply Corp. stores and treats drinking water in a 35-acre reservoir and treatment complex, supplying a large part of Hidalgo and Willacy counties, in addition to Port Mansfield.

""We're worried about it polluting the water supply, either from blowing debris, from birds, from underground water or a broken water line on the property,'' says Milton Kersten, the manager of the non-profit water company.

Kersten said the principal water line from the plant -- made of 10-foot sections of concrete pipe with rubber gaskets -- runs along the east and north side of the BFI tract.

The water company recently obtained financing to double its water output -- from 4 million to 8 million gallons a day -- in anticipation of delivering water to 37 substandard ""colonias'' in the Valley.

""We have a 16-inch line on the east side of the property with 100 pounds pressure and it could blow out or get hit when they are digging and wash a hole in their landfill,'' says Kersten. ""Or we could get infiltration from the landfill.

""And we've been told there are certain chemical materials in

the landfill that could dissolve the rubber gaskets in our waterlines."

Dr. Roger Boren, who runs a chemical testing laboratory across the highway from the proposed landfill, envisions his neatly landscaped business festooned with plastic bags and other windborne trash from the landfill.

But he, like his neighbors, worries more about the less visible danger of toxic materials seeping into the groundwater or invading water pipes.

""The landfill permit states specifically that the landfill will accept empty pesticide, herbicide, fungicide and rodenticide containers, infectious and pathological wastes, dead animals and slaughterhouse wastes and septic tank and portable toilet wastes," says Boren.

Boren and other opponents have challenged BFI's assertion they can successfully plant grass in six inches of dirt on the top and sides of the landfill to prevent erosion. And they say the garbage in the landfill will attract thousands of grackles that could set up housekeeping in nearby citrus groves.

Citrus farmer Jimmy E. Steidinger, one of the principal opponents to the landfill and a founder of the water company, wonders why BFI doesn't put a landfill in non-productive land on the eastern end of Hidalgo County.

""There's a lot of land out there, with caliche pits, that won't even grow weeds that they could use if we needed one,'' says Steidinger. ""That they (BFI) would take some of the best productive land we have makes me think they don't have any respect for our land, and as a farmer that makes me mad."

Mary Jane Valentine, the BFI project manager, says the flow of groundwater is away from the Alamo water supply reservoir.

""We don't see how the landfill can contaminate that reservoir,'' says Valentine. ""And if anything should leak, our monitoring would detect it at our property line and we could do cleanup if necessary."

The landfill will be constructed with a bottom lining of clay three feet deep, and depending on new federal regulations, an additional synthetic liner may be required, Valentine said. Health Department officials have said it would take 29 years for liquids to seep through the layer of clay lining the bottom and sides of the landfill.

Still, Valentine said the landfill will not be welcome anywhere it is located.

""No matter where we go, everyone is going to be mad. If we were going to move away from Dr. Boren and Jimmy Steidinger and go 50 miles away to Starr County, those people would be mad,'' says Valentine. ""I mean, nobody wants a landfill. Nobody wants it no matter where you put it."

But farmer Steidinger and Boren, the chemical researcher, say the Texas Department of Health rubber-stamped BFI's application and ignored many facts developed by experts the citizens's group brought to public hearings.

And correspondence between the Health Department and concerned citizens indicates that state officials want BFI to operate a facility, which would become Hidalgo County's fourth operating landfill.

For example, on May 28, 1991, Health Department official T.A. Outlaw Jr. wrote a reply to a protest letter sent to Gov. Richards by one Donna resident.

""Facilities in the county range from perhaps the worst landfill in the state, city of Donna (which has been referred to the attorney general), to composting, to landfills of adequate capacity,'' wrote Outlaw, an engineer who is chief of the Bureau of Solid Waste Management.

""A well-designed, properly operated landfill is needed in your county."

However, in an 1989 letter to Steidinger's wife, Health Department official Hector H. Mendieta wrote that ""need is not one of the criteria that we evaluate in determining the suitability of a site for a landfill."

Mendieta, director of the Division of Solid Waste Management, made a number of errors in his five-page letter, according to Steidinger and Boren.

""The prevailing winds in that area are from the southeast, blowing toward the northwest. Since the treatment plant is located south-southwest of the landfill site, any windblown material escaping the site will be blown away from the water plant," Mendieta wrote.

Steidinger said data from the Texas A&M extension service office in Weslaco, within a few miles of the site, indicate the wind blew from the north 106 days in 1990.

Mendieta wrote that ""BFI, in our opinion, (and as reflected in the Department's files), has a commendable "track record' in operating their existing sites."

The health official added: ""It was also our opinion that the site could and would be properly operated by professionals who have been in this business for many years and whose sole endeavor is the safe and proper handling and disposal of solid waste."

Steidinger counters this flattering assessment with records his group obtained from the Health Department outlining repeated violations at four BFI landfills in Harris County, as well as landfills in Bexar, Travis and Galveston counties.

The Health Department inspections noted contamination seeping from landfills into bayous and drainage ditches, illegal dumping, uncovered hospital waste and numerous cases of erosion of the landfill sites.

BFI's record in operating hazardous waste dumps in a number of states is much worse.

In March 1990, the Environmental Protection Agency announced that BFI and a subsidiary agreed to pay $1.55 million in fines to settle 1,400 violations of federal law found at a hazardous waste disposal site in Calcasieu Parish, La.

In August 1988, BFI and its subsidiary paid a $2.5 million civil penalty for similar violations at a hazardous waste facility in Livingston, La.

A BFI official said that the company purchased the Calcasieu Parish site from another company and was unaware of previous contamination at the time of purchase.

Valentine, the BFI project manager, says all that is in the past since the company has sold its hazardous waste division.

""That's why we got out of the hazardous waste business, we realized we couldn't do it,'' says Valentine. ""Yes, we were fined, but fined not for pollution violations or for harming the environment."

Roger Meacham of the Dallas EPA office, however, said the Louisiana penalties were assessed for ""actual pollution, groundwater contamination."

Valentine defended BFI's record on landfills that do not accept hazardous wastes, such as the one proposed near Donna.

""I can't deny it, we've had violations. We've not had any serious violations and we haven't paid any fines. If they follow the correspondence (with state officials), they find the violations were taken care of immediately,'' she said.

Earlier this month, lawyers hired by the citizens group went

to Austin to argue their case before the 3rd Court of Appeals after losing in district court.

The protesters filed suit because the Health Department instructed BFI to change the design of the landfill because of the shallow water table beneath the property. BFI contended it was six feet beneath the surface, but soil experts said it was shallower.

The protesters say their rights of due process were violated because the Health Department has not conducted public hearings or released information on the changes BFI made to the landfill design.

While the controversy winds through the courts, the citizens of the area continue to fight.

Most of the families who live near the landfill site have children who ride buses to school on the main road, FM 943, and many are concerned that a fleet of 40 garbage trucks might dangerously congest the heavily traveled roadway.

Many of the residents are middle-class Mexican-Americans who have struggled to buy property and build decent homes for their families.

""You can see everything is pretty here, it's clean. The homes are pretty,'" says Modesta Guarado, vice-president of the citizens' group CALL.

""But when they build it, it doesn't matter how tall the fence is, it will be terrible. It will be a crime."

Property owner sues BFI, claiming contamination from landfill

Andrea F. Siegel
Sun Staff Writer

The nation's second-largest waste handler was sued for $100 million this week in federal court by a man who says its Solley Road landfill has contaminated his adjacent land with hazardous waste so badly that he cannot develop it.

John C. Blumenthal, whose Blumenthal Power Co. Inc. owns 145 acres between the closed landfill and Marley Creek, has proposed building a 738-home subdivision on the site. But cancer-causing chemicals from the landfill, owned by Browning Ferris Industries, have turned up in test wells on his property.

Contaminated ground water has been moving west toward Marley Creek at about 100 feet a year, according to the federal Environmental Protection Agency. A second plume was detected this year.

BFI spokesman Peter Blocker said company officials were not surprised by the suit but could not comment because they had not seen it.

The suit, filed Wednesday in U.S. District Court in Baltimore, claims that BFI violated a 1991 agreement not to allow hazardous contaminants to seep into Mr. Blumenthal's property.

It seeks $20 million in compensatory damages, $20 million in special and incidental damages, and $60 million in punitive damages.

Despite the allegations, BFI's stock prices should remain stable, said Marc Sulam, an analyst with Kidder Peabody & Co. in New York. The firm "has one of the strongest balance sheets among all of the environmental service companies in this country," he said.

BFI closed at 29 1/4, down 1/8, on the New York Stock Exchange yesterday.

Mr. Blumenthal said yesterday he met with BFI officials on July 6, before test wells installed on his land turned up trichloroethylene, benzene and other hazardous chemicals. The sides could not reach an agreement.

Now he cannot obtain financing for his development. "My financier does not feel it is a risk worth taking knowing there is a level of contamination on the site," he said.

"If you can't get financing, you have a worthless piece of property," explained Thomas Guckenburg, a North County real estate broker.

BFI purchased the Solley Road landfill in 1973 and began operating it as a licensed, hazardous-waste landfill in 1977. It was closed in 1982. Two years later, the Maryland Department of the Environment said hazardous waste was seeping into the ground water.

Now, environmental protections are failing. BFI is seeking federal permission to reseal the trash hills. It built a network of pipes and aerators last year to clean the underground water and return it to the ground, but shut that down in March because it was blocking the aquifer.

The company, which is is hauling the water off-site temporarily, has asked the state for permission to dump the cleaned water into an intermittent stream that empties into Marley Creek, but community leaders and government officials fear that would set back their efforts to clean up the creek.

State cites BFI for damaged liner

A DER waste specialist says a tear in the material lining a cell allowed leachate seepage. BFI disputes the charges and asks for a meeting with the agency.

The state Department of Environmental Resources has cited Browning-Ferris Industries Inc. for an incident in late February when a liner at its landfill in New Morgan was damaged.

DER solid waste specialist Tim Leon Guerrero said the firm was cited Monday for failing to immediately notify state officials of the rip, and for illegally discharging leachate from the landfill, which opened in January.

Leon Guerrero said he was unaware what fines the company could face for the alleged violations. BFI officials, meanwhile, denied the charges, and said they plan to schedule a meeting with DER regarding the charges.

The incident occurred Feb. 24 when a Berks County Prison inmate, breaking up ice accumulations in an unused cell while working at the landfill under a work-release program, punctured a temporary liner that covers an embankment between an active cell and an inactive one.

BFI spokesman Carl W. Brown Jr. reiterated Tuesday previous company claims that tests conducted after the tear showed no leachate leaked from the active cell into the unused one, or into a nearby sediment basin and a tributary of the Conestoga Creek.

The only liquid found with traces of waste in it, he said, was in the active cell.

Brown also said the company properly notified regulatory officials about the tear. He said the company's permit requires the state to be told of such incidents within 24 hours after they occur, and that was done.

Leon Guerrero said DER does not dispute the test results. ""We're pretty much agreed with what the landfill is saying," he said. ""Our contention is, however, that the material did originate from the active cell, therefore it was leachate, and it was therefore an unpermitted discharge."

Leon Guerrero also said DER was to be notified immediately in the event of an emergency. That includes, he said, a spill threatening public health and safety, public welfare or the environment and personal injury.

Portage officials fight landfill's bid to stay open

NORMAN PARISH; PLAIN DEALER REPORTER

RAVENNA

Portage County officials and some angry residents are gearing up to battle an Atwater Township landfill's appeal to continue operating after it was denied a state permit last year.

Ohio Environmental Protection Agency officials denied Willowcreek Landfill, owned by Browning-Ferris Industries Inc., a permit because the landfill was too close to private wells, streams and ground water.

But the landfill continues to operate while it appeals the EPA's decision, and that has outraged county officials and some residents.

A hearing on the appeal is scheduled for Jan. 13 in Columbus. County officials said they would have a lawyer at the meeting to fight the appeal.

John Watkins, group leader of the EPA's Northeast District in Twinsburg, said landfill and EPA officials were discussing whether the operation could move to two other areas of BFI's more than 200-acre site, where it wouldn't violate EPA rules.

Atwater resident Joan Ellsworth is planning a meeting of her own because she doesn't like the landfill's fumes and says it poses environmental problems. She has scheduled a meeting to discuss the issue with residents Jan. 8 at Waterloo Elementary School in Atwater.

"The landfill should just close," said Ellsworth, president of Residents Against Garbage Environment, a group opposed to the landfill. Ellsworth, who lives near the landfill, owns a golf course nearby.

"The odor is terrible," she said. "It smells like dead bodies over there. It almost knocks you out. You are just gasping for air. We are fighting this tooth and nail. Our property values have dropped. The stench is so bad you can't sit outside. The smell is just atrocious over there. The roads even stink. If you live next to the landfill, you have to live like a second-class citizen."

Landfill officials could not be reached for comment.

Charles Ramer, coordinator of the Portage County Solid Waste District, also criticized the landfill.

"It is not an appropriate site for a landfill and cannot realistically be brought into compliance," Ramer said.

If BFI wins the appeal or reaches a settlement, the solid-waste district's options on how and where to dispose of its waste could be narrowed, because of a law that says districts must use all available facilities to the maximum possible extent. That would mean using the BFI landfill.

The district has a 20-year plan for managing trash, which includes using some landfill fees to form an economic-development grant-and-loan fund for companies that use recyclable materials.

THEY'RE DOWN ON THE DUMP EXPANSION OF LANDFILL DRAWS PROTEST

MOLLY KAVANAUGH PLAIN DEALER REPORTER

Homeowners on Butternut Ridge Rd. like to joke about their "dumpfront property," across the street from "Mount Trashmore."

But what is happening in their neighborhood is no laughing matter, they say.

Browning-Ferris Industries wants to expand its landfill off Butternut Ridge Rd. by 102 acres. The current landfill is 190 acres and will reach capacity in six to eight years.

"We really thought we were done with the fight when this one filled up," said Pat Justin, who lives west of the landfill on Butternut Ridge Rd.

In the early 1980s, BFI came to the township seeking approval for its current landfill. Justin and her husband, Rick, and others objected, but consoled themselves with a BFI-township contract that they thought prevented future landfills.

They apparently were wrong and now plan to fight the proposed one.

"We're not going to shut up," said Lynn Suleski, who lives on Ohio 511 near the front of the landfill. Among the group's complaints are noise and odor.

Tomorrow, the group will attend a trustees' hearing on BFI's expansion request. The zoning commission has already given its approval.

Trustee Richard Williams said trustees could vote on the matter as early as tomorrow, depending on what is said at the hearing.

Williams was not a trustee during the last go-around, and he was against the landfill. But times have changed, he said.

"Landfills are 100 percent better managed than they were 15 years ago," he said.

The current landfill's slope also will increase, to 90 feet from 30 feet, but the trustees have no control over that, Williams said. The Ohio Environmental Protection Agency regulates landfills, and BFI was given approval for the higher slope a year ago.

In exchange for letting BFI build a new landfill, the township would get a one-mile landscaped berm with mature trees along Butternut Ridge Rd., which would help camouflage the slope, Williams said.

David Matthews, district vice president of BFI, said New Russia Township residents also will continue to get free garbage and recycling pickup.

"I'd rather pay to have it picked up," said Sue Gerhardinger, who also lives on Butternut Ridge Rd.

BFI owns 1,400 acres spread over New Russia and Carlisle townships. About 240 acres is being used, and there are no proposals for additional landfills beyond the proposed one, Matthews said.

Settlement in BFI case considered
By Marshall Wilson

San Mateo, CA, US --

HALF MOON BAY--Water-pollution officials were to consider a proposal today that requires Browning Ferris Industries to pay $900,000 to restore coastal streams filled with mud when construction dams burst last year.

The Oct. 29 spill was the worst case of sediment pollution in Bay Area history, investigators for the state Regional Water Quality Control Board said.

The board was to meet in Oakland today to consider a proposed settlement tentatively agreed to by BFI, the state Fish and Game Department and the water board's staff. The state Attorney General's Office negotiated the agreement on behalf of the public agencies.

The agreement calls for BFI to pay $900,000 to the Pilarcitos Creek Restoration Fund. The money would be used to restore habitat along the watershed inundated when a wall of water gushed down Corinda Los Trancos and Pilarcitos creeks when the dams burst during the first heavy rains of the season.

In addition, BFI would pay $100,000 to the state Water Pollution Cleanup and Abatement Account, a fund that pays the cleanup costs of spills. BFI would also reimburse the state agencies charged with investigating the spill up to $75,000.

Approval of the agreement would end any criminal or civil proceedings against BFI.

In agreeing to the settlement, BFI denies any wrongdoing. The denial of liability means the agreement could not be used against the company in any other legal action brought against it by other parties.

The Oct. 29 spill occurred when storm water overflowed earthen dams, causing the dams to fail. The dams were being used to contain water during expansion work at the company's Ox Mountain Landfill, San Mateo County's largest dump.

Investigators said the flood left the streambeds buried under a thick layer of mud and killed steelhead trout and other fish.

The agreement calls for BFI to pay half the $900,000 within 30 days. The balance would be paid 10 days after BFI begins use of the expanded landfill area or by June 1, whichever comes first.

Fish and Game biologist Ken Aasen said an advisory committee of community leaders and wildlife experts will be established to determine how to spend the $900,000.

Possible projects include planting native vegetation along the streams, removing sediment from the creeks and creating pools.

Class-Action Suit at Pittsburg Dump / Homeowners concerned with health problems, lower property values

Erin Hallissy, Chronicle East Bay Bureau

. A group of homeowners living near the Keller Canyon Landfill in Pittsburg filed a class-action lawsuit yesterday, saying that the dump is lowering their property values and causing health problems by allowing dust and trash to blow over their homes.

The suit, filed in Contra Costa County Superior Court, argues that Browning-Ferris Industries, which owns the dump, could be using safer methods to cover trash each day than piling on dirt that blows away when the wind picks up.

Tom Bruen, an attorney for Browning-Ferris Industries, said yesterday that the plaintiffs' attorneys are "misinformed" about their allegations of health problems and diminished property value.

"There's simply no evidence to support the plaintiffs' allegation that any property damage or personal injury has been caused by the landfill," Bruen said.

The Hillsdale subdivision of 1,200 homes is less than 200 yards from the dump's boundaries and in the direct path of winds that blow "dust, litter, toxic substances and odors," the suit claims.

About 7,800 other homes in the surrounding area of Bay Point and Pittsburg are also affected by operations at Keller Canyon and should be included in the class-action suit, attorneys for the plaintiffs said.

The lawsuit is the latest round in a series of fights over Keller Canyon, which opened in May 1992. To receive permits from county and state agencies, Keller Canyon had to fend off legal challenges in court and escalating complaints about high garbage rates at the "state-of-the-art" landfill.

The suit says that a large earthen berm that has been built as a buffer between Keller Canyon and the nearby homes is an eyesore that illustrates their daily problems with the dump.

"The earthen wall of the garbage dump towers over the community as a constant reminder of the invasion of plaintiffs' neighborhood and the permanent impairment of the quality of their lives," the suit says.

Residents say that excavation and dirt-moving at the site, which is supposed to continue for more than 30 years, also causes constant problems. Each day, six inches of dirt is placed over the new trash -- an area that can be as large as three acres, the suit says.

"The constant and recurring process of moving dirt and spreading it over the trash results in unreasonable amounts of unhealthful dust," which is carried onto neighboring homes and causes recurring respiratory problems and visual irritation and injuries, according to the suit.

"This is making these homes unfit for their residential purposes and is also causing personal injuries," said Michael Ram, one of the plaintiffs' attorneys.

The suit suggests that instead of using dirt to cover trash, the company could use a man-made landfill cover called "Aqua-Shed," which sticks to waste like flypaper and is impermeable to gases and rainwater.

Browning-Ferris attorney Bruen noted that a U.S. District Court judge dismissed a federal class-action suit by the same plaintiffs earlier this year, saying that it was not "ripe" because some of the issues should have first been heard in a state court.

GM, landfills may be fined $35 million in PCB disposal EPA says sludge with high levels of toxicant buried

The Associated Press

General Motors Corp. and two landfill operators face fines of $35 million or more for burying sludge allegedly containing high levels of cancer-causing PCBs in Ohio, Alabama and New York state, the government said Monday.

The Environmental Protection Agency said the sludge should have been incinerated.

A General Motors forge in Massena, N.Y., near the Canadian border about 75 miles southwest of Montreal, generated about 30,000 tons of the sludge, the EPA said. The agency said CWM Chemical Services Inc. and Cecos International Inc. buried it in landfills in the three states.

General Motors and CWM officials disputed the EPA's conclusion that the dumping was illegal. Browning-Ferris Industries, Cecos' parent company, had no immediate comment.

The EPA's complaint proposed fining General Motors $14.1 million for generating the waste. Cecos and CWM would be fined $14.1 million and $7 million, respectively, for the portion that was dumped in New York state.

Melissa Jaeger, an EPA spokeswoman, said EPA regional offices with jurisdiction over the Ohio and Alabama landfills may decide to assess additional fines for the dumping in those states.

Jaeger said all of the fines are negotiable if the companies offer to change their behavior.

The EPA said the sludge, dumped from February 1984 to October 1987, contained more than 500 parts per million of polychlorinated biphenyls, or PCBs, chemicals once widely used as industrial coolants but banned for most U.S. uses since 1979.

General Motors is allowed to use up to 50 parts per million of PCBs in hydraulic fluid at its forge, and waste containing higher concentrations of PCBs may be disposed of legally. But the waste must be incinerated if the concentration is higher than 500 parts per million, the EPA said.

Although General Motors' hydraulic fluid and sludge contained more than 500 parts per million of PCBs, the company mixed it with sand and limestone and shipped it off to be buried in landfills, the EPA charges.

General Motors has some "technical disagreements over sampling and analysis issues" with the EPA, and is drafting a formal response to the complaint, said Ben Ippolito, a spokesman for the company's central foundry division in Saginaw, Mich. He declined to be more specific.

Jaeger said a Cecos landfill in Niagara Falls, N.Y., received 16,360 tons of the waste, and 10,000 tons were buried in a CWM landfill north of Niagara Falls. The Cecos landfill is being shut down, leaving the CWM facility as the only licensed hazardous-waste dump in New York state.

Of the rest of the sludge, 3,000 tons went to a CWM landfill in Emelle, Ala., and about 500 tons were buried in a now-closed Cecos landfill in Williamsburg, Ohio, she said.

CWM General Manager John J. Stanulonis said the company plans to contest the allegations.

"It is our belief that we did take the material and that we did properly dispose of it in accordance with our permits and procedures," he said.

EPA Says Two Units Of Browning-Ferris Fined $1.55 Million

DALLAS -- A regional office of the Environmental Protection Agency said two Louisiana-based units of Browning-Ferris Industries agreed to pay $1.55 million to settle allegations that the companies violated hazardous waste-disposal regulations.

The latest settlement marks the second time in two years that the waste disposal concern has paid fines to settle alleged violations at its Louisiana facilities.

The EPA said the most recent fine resulted from allegations that Browning-Ferris failed to properly maintain hazardous waste disposal pits, conduct inspections, train personnel and keep records. The agency said it had found 1,400 violations at a facility operated by two units, Browning-Ferris Industries Chemical Services Inc., and CECOS International Inc. That facility is in Calcasieu Parish in southwestern Louisiana.

The allegations arose from inspections the EPA made of the facility in December 1985 and January 1986. Browning-Ferris will make equal payments to the federal government and Louisiana.

Browning-Ferris spokesman Peter G. Block said the violations at the Calcasieu facility "at no time posed a health hazard." However, EPA spokesman Roger Meacham said, "The potential threat is there. That is why we want to see that the requirements of the federal regulations are followed to the letter."

Mr. Block said Browning-Ferris had been taking steps to correct the problems even before the company signed a consent decree to settle the case Tuesday.

Ascension Police Jury condemns BFI expansion plan * * * DEQ will be asked to revoke landfill permit

Tim Talley
RIVER PARISHES BUREAU

DONALDSONVILLE _ A proposal by Browning-Ferris Industries Inc. to expand the service area of its solid-waste landfill near Sorrento was condemned Thursday night by the Ascension Parish Police Jury and local environmentalists.

Following lengthy discussion on the subject, the police jury adopted a resolution against BFI's plan to haul wastes to the non-hazardous Colonial Landfill from within a 200-mile radius and requested a public hearing on the proposal.

Jurors also asked the Louisiana Department of Environmental Quality to revoke BFI's permit to operate the landfill and issue another one restricting BFI's use of the dump to wastes generated in the parish.

BFI's state permit allows it to haul in wastes from neighboring parishes in addition to waste products from Ascension.

The state is accepting public comments on BFI's request to modify its DEQ permit and allow wastes to be trucked in from a distance of 200 miles. The 200-mile radius would include most of Louisiana and parts of Texas, Mississippi and Alabama.

Jurors, residents and representatives of parish environmental groups said they object to the proposal. The additional wastes will exacerbate the parish's chronic pollution-control problems, they said.

"We don't want to be the dumping ground for Louisiana," said Juror Marvin Braud of Gonzales.

"I am personally opposed to taking care of somebody else's waste," said Theresa Robert of the environmental organization Save Ourselves, Inc.

"We have enough problems," said Charlene Melancon of Sorrento. Melancon lives adjacent to the Cleve Reber abandoned hazardous-waste dump near Sorrento and said that dump began as a solid-waste facility.

"We are really opening ourselves up to something that we won't have any control over," said Ruby Cointment of SOS. "I think it boggles the mind."

"There are sins of the past all around us, and we don't want to create any more," said Tom Nicholson, district manager of the Colonial Landfill.

"We're not a hazardous-waste landfill," he said. Colonial is a non-hazardous industrial-waste facility and is not permitted to accept hazardous wastes, Nicholson said.

The type of substances disposed at the landfill are public information, and Nicholson invited jurors and environmentalists to visit and site and learn more about BFI's proposal.

Residents complained about odors from the site and dumping late at night. Jury Vice President Johnny Ramirez said the after-hours activities are inconvenient to local residents.

Nicholson said off-hours dumping is done only when customer request and is reported to DEQ, which has the authority to have an inspector on hand during the operation.

Juror Joseph U. Pierre suggested the parish ask for increased monitoring of BFI's activities to prevent odors and other problems.

Jurors expressed concern that the dump will fill up when wastes trucked in from other areas and parish residents will have to pay more to have their wastes trucked to landfills in other areas.

Nicholson said only about half of Colonial's 300 acres are being utilized. He said more wastes can be hauled into the landfill and it still will last until after the year 2000.

On another matter, the police jury adopted a resolution requiring a two-thirds vote to remove the jury president, secretary-treasurer and parish manager. The Louisiana Legislature must concur with the resolution before it becomes law.

Officials previously could be replaced by a simple majority of the 11-member jury. A majority vote will remain all that's required to appoint them.

Juror Shafter Kling said the change will instill more public confidence in the jury and its top officials.

Juror Charles Parent indicated that proposed changes to parish government contained in a home-rule charter motivated the jury's action.

METRO DU PAGE

VIOLATIONS AT LANDFILL SPUR ACTION

An area waste hauler has been charged with permit violations in conjunction with the operation of Mallard Lake Landfill, near Hanover Park, the DuPage County state's attorney's office said Monday.

The civil complaint alleges that Browning-Ferris Industries of Illinois Inc., and its subsidiary, E&E Hauling Inc., deposited waste in areas of the landfill in amounts that exceeded the operating permit specifications allowed by the Illinois Environmental Protection Agency.

According to DuPage County State's Atty. Joe Birkett, the parties have agreed to a consent order to address the issues raised in the complaint. The consent order, scheduled to be filed soon, is intended to resolve and conclude the matter, Birkett said.

Under the terms of the agreement, to compensate for overfilled areas, BFI and E&E Hauling will not fill certain remaining areas of the landfill to capacity.

E&E Hauling also will reimburse the county for expenses incurred during the investigation of landfill irregularities, officials said.

AREA/STATE

GROUP SAYS LANDFILL GASES MADE THEM ILL

Tom Campbell Times-Dispatch Staff Writer

Bad-smelling gas from the Caroline County landfill give people who live nearby symptoms including nausea, vomiting, headaches, watery eyes and breathing difficulties, witnesses have testified in federal court.

Just how sick they get and whether the sickness is "a substantial endangerment to health" is the legal issue a coalition of 55 county residents placed before U.S. District Judge Robert E. Payne yesterday at the close of two days of testimony.

The residents -- the Caroline County Landfill Closure Group -- sued the county and Browning-Ferris Industries, alleging that the landfill was making them sick and posed a health threat.

BFI was made a party because, about two years ago, it began dumping construction waste in the Caroline landfill, including drywall scrap containing gypsum, which the residents allege brought on emissions of hydrogen sulfide and similar gases.

"I woke up one morning and couldn't breathe," said Darrel Webb, whose house is about 300 yards downhill from the landfill. "It was smelling really bad and I just couldn't get my breath."

By the time he got to a hospital, symptoms had subsided and no diagnosis was made, Webb said. He said the sulfur smells continued and at times his two children could not go outside. Webb said his head frequently ached.

BFI lawyers and witnesses dispute the residents' claims that toxic gases from the landfill make them sick. One doctor testified that Webb's headaches were derived from sinus problems and are not related to hydrogen sulfide exposure.

Marcia French testified in February that the smell became so bad it woke her up in the middle of the night. Her house is about 200 yards from the landfill section where BFI dumped.

"The odor in our bedroom was really extremely bad," French said. "It was a sewer odor."

Sleepy and thinking the smell was from inside the house, she opened an outside door, expecting to take a deep breath of fresh night air.

Instead, the air outside was much worse, French testified. She had just enough time to run into the bathroom before she vomited. Nausea and a severe headache lasted into the following day, she said.

"I was just very, very ill," French said.

Webb and other residents sought help from the small county government, which made repeated attempts to solve the problems, and eventually from the state and federal governments.

Webb said the group decided last year to pool resources and hire an environmental lawyer, David S. Bailey, as fix after fix proved to be ineffective and they still were living with the smells.

"We thought, the county has had a year to fix this -- OK, what do we have to do to get it fixed ourselves?" Webb said.

Currently the gas-producing section of the landfill has been closed and wells have been installed to burn off the gas. Episodes of bad odors at his house now occur only about twice a month, Webb said, but residents want the problem resolved completely.

Originally, the federal lawsuit included damage claims linked to state statutes, but the judge refused to hear them. Based on those claims, the residents filed a similar $30 million lawsuit in Richmond Circuit Court that still is pending.

Yesterday Payne said he wants written arguments from both sides to help him decide what "substantial endangerment to health" means in this case.

He set a Feb. 13 hearing date for oral arguments and will decide the issue after that. But he urged both sides to work toward an out-of-court settlement before then.

"I would think creative lawyers ought to be able to work that out," the judge said.

BFI sued here on monopoly charges

Charles Conner The Commercial Appeal

The federal government sued Browning-Ferris Industries and its Tennessee subsidiary Thursday for unlawfully thwarting waste-hauling competition in the Memphis area.

In court documents, the U.S. Justice Department said Browning-Ferris Industries of Tennessee Inc. controlled more than 60 percent of the Dumpster business in the Memphis area and dominated the small container segment for more than a decade.

The Justice Department said the company intentionally used restrictive contracts to inhibit competition and enhance its power over commercial customers, such as restaurants, apartment complexes, retailers, office buildings and industrial parks.

Such contracts were long-term and renewed automatically. "Many of these contracts contain terms . . . make it more difficult and costly for customers to switch to a competitor," the government said. "As a result, there is a dangerous probability that Defendants will achieve monopoly power in the relevant markets."

BFI and BFI Tennessee agreed to settle the lawsuit with the Justice Department Thursday.

In court documents, the companies agreed to make changes in their contracting practices in the Memphis area. The tentative settlement must still be approved by a federal judge in Washington.

Such changes should mean greater competition and result in lower prices, government officials and Memphis area economists said Thursday.

"The potential for competition is at least being enhanced by such a settlement," said Thomas O. Depperschmidt, professor of economics at University of Memphis, whose areas of expertise include antitrust economics and government regulation of business.

The key, he said, is the number of companies that might move in to try to win that business.

Dr. David Ciscel, another UM economics professor, agreed. "Prices are likely to fall over the next two to three years as other firms see the opportunity for selling less expensive refuse hauling services."

The Justice Department took action Thursday against BFI for its practices in Memphis and Dubuque, Iowa. The government also took action against Waste Management Inc. for thwarting competition in Savannah, Ga., and central Louisiana.

The markets that the Justice Department tackles are evaluated on a market-by-market basis, said Anne K. Bingaman, assistant attorney general for antitrust with the U.S. Department of Justice in Washington.

"What we found was a three-year, rollover contract that had the affect of keeping out new entrants and maintaining higher prices," Bingaman said in an interview.

Brett Frazier, vice president of investor relations with BFI in Houston, said the Justice Department has spent two years to change one class of service in two relatively small markets, Memphis and Dubuque.

That, Frazier characterized, has been an "inefficient use of (Justice) time."

Meanwhile, said Frazier, BFI has been struggling for more than 2 years to enter the "noncompetitive, $1.5 billion New York City market. It's noncompetitive because it's run by the Mob and the Justice Department has done nothing there."

The Justice Department defined BFI's Memphis area market as Shelby and Fayette counties; Crittenden County, Ark.; and DeSoto, Marshall, Tate and Tunica County, Miss.

It said BFI generated revenues of more than $40.9 million in its 1994 fiscal year from operations in Tennessee, Arkansas and Mississippi.

Under terms of the settlement, BFI and BFI Tennessee Inc. agreed to limit initial customer contract terms to no more than two years and renewal terms of one year. The companies agreed not to require its customers to give more than 30 days notice before termination.

In addition, the settlement agreement also prohibits BFI from entering into any contract that "is not easily readable and is not labeled, in large letters, CONTRACT FOR SOLID WASTE SERVICES."

BFI's Memphis district manager was out of the office Thursday and not available for comment.

The company employs about 400 workers in the area and operates two large landfills in Shelby County. Included is a 959-acre site

southwest of Millington and another landfill on Malone Road, just south of Holmes in the southern portion of the county.

Neither BFI or Waste Management acknowledged any wrongdoing in the settlement their lawyers negotiated with the Justice Department.

The companies also agreed that contracts wouldn't require customers to give them exclusive rights to all solid waste and recyclables.

The settlement with Waste Management, now known as WMX Technologies, was filed in a Savannah federal court.

The agreement with BFI was filed in a Washington federal court. Both must be approved by a judge.

The agreement wasn't the first time the Justice Department raised questions about the waste hauling industry.

Federal investigators in Memphis began looking into the garbage hauling practices of BFI back in 1986.

And in December 1994, BFI negotiated an agreement with the Justice Department, pledging to end restrictive Dumpster contracts in Maryland and Florida as one condition for U.S. antitrust clearance for its acquisition of rival Attwoods PLC.

BFI posted revenues of more than $4 billion during 1994. And their shares rose 25 cents to $29.62 1/2 in trading Thursday at the New York Stock Exchange.

WMX generated revenues of $5.8 billion last year. Its shares were unchanged at 28.62 1/2 in NYSE trading.

BFI, the waste disposal company, has long record of fines, suits, penalties

Andrea S. Brown

Although it has abandoned plans to build an East Hempfield Township facility to process medical waste, Browning Ferris Industries continues to be active in other projects in Pennsylvania. One nearby project involves its plans for a 154-acre landfill in Berks County, near Morgantown. This article, based mainly on court documents, shows that Browning Ferris has been successful in getting approval for numerous projects across the country despite a record that raises questions about the company and its management.

When Browning-Ferris Industries dropped plans for a medical waste treatment plant here last month, Lancaster County escaped a close encounter with a conglomerate with a nationwide record of environmental mishaps and pollution offenses.

Beyond that, BFI has been accused of having criminal connections and of threatening its opponents. It has been convicted of anti-competitive practices that have jacked the prices of waste disposal to exorbitant levels in some communities.

All these charges are denied by BFI. In glowing letters of recommendation the company filed with the state Department of Environmental Resources, BFI is described by officials from areas where the firm operates landfills as "a good neighbor," a "first-class operation," a company "always concerned with the protection of the environment."

In its 1990 annual report, BFI says its medical waste subsidiary's very existence is "a direct response to community concern for its health and the environment."

Spokesman Peter Block says the firm "has compiled an excellent safety record over the years. It's been continuous improvement."

But opponents vehemently disagree, and BFI's own record contradicts what Block says.

"They're convicted felons. They have a history of convictions for price fixing, predatory pricing, and dumping toxic waste in the drinking water supply," says Brian Lipsett, of the watchdog group Citizens Clearinghouse for Hazardous Waste.

The Wall Street Journal says the company's image is considered "less than trustworthy" by many.

A group of BFI's own shareholders accuses the firm's board of directors of "long-standing and egregious misconduct, waste, mismanagement and other wrongdoing" in a lawsuit filed in federal court.

The shareholders' charges include bid rigging, ties to organized crime, an alleged bribe of a Texas state senator, insider trading and environmental recklessness.

Instead of disciplining the individuals responsible for such practices, the company has actually rewarded and promoted some of them, the shareholders allege.

Which image is the accurate one?

The community-minded, environmentally concerned good neighbor?

Or the price-fixing, polluting corporation that breaks rules as a way of life?

Active in Penna.

In Pennsylvania, environmental officials seem to have decided in BFI's favor.

The company has filed a huge binder representing its environmental history for the past ten years with the state Department of Environmental Resources.

Before granting a permit, DER agents at regional offices, like the one overseeing the application for the infectious waste autoclave that BFI planned here, must review that Compliance History and decide if it is acceptable.

The office in charge of the aborted Lancaster County project had not yet looked at BFI's Compliance History when the company backed out, according to Robert Binvin, who was responsible for the review.

But the DER office in Conshohocken, which recently granted BFI a permit for a Berks County landfill where more than 5,000 tons of waste will be dumped each day, apparently decided that that same history passed muster.

"It's kind of difficult to say how bad a Compliance History has to be to affect the application," said Binvin. "One thing is that if the applicant is currently in violation of some

environmental regulation, we would not be able to issue the permit."

But a long record of environmental mishaps need not stop a company from getting approval to open new operations in Pennsylania, Binvin said, provided the problems have been corrected and all fines and penalties have been paid.

As for BFI, said Binvin, "They are probably considered to be in compliance right now."

But what about a history of serious violations involving non-environmental issues _ issues like bid-rigging, in which BFI has been proven to have been involved?

Binvin said that if the state attorney general's office is currently investigating the company, that would hold up an application, but if not, such violations are not part of DER's decision about whether or not to grant a permit.

In February, BFI signed a seven-year contract with the city of Philadelphia to dispose of 70 percent of its municipal solid waste. The company estimated the value of the contract at $210 million.

The company also operates several landfills around the state.

BFI's Alan P. Magan, project manager for what would have been BFi's autoclave here, says that in all the years BFI has been applying to DER for permits for various waste disposal businesses, the state agency has never expressed any concern about the company's history of environmental violations and litigation.

"We've been getting permits right along," he says. "There's not been a problem."

Civil suits, penalties

Much of the evidence on BFI's environmental record comes from the company itself.

In the 10-year, company-compiled history in DER's files, BFI lists scores of incidents in which BFI and its subsidiaries were cited, fined, indicted or convicted on charges of violating state and federal environmental regulations. (In this article, any reference to BFI includes its subsidiaries.)

It also records millions of dollars BFI has paid to settle civil suits _ often without admitting guilt _ related to how it handled waste, including dangerous chemicals.

In all, BFI admitted a record of 270 civil penalties, administrative orders, permit or license suspensions and

revocations, and bond forfeiture acts; 10 misdemeanor or felony convictions and pleas; 24 court decrees or settlement orders, and one pending court case.

More than a dozen listings involve medical waste, which is what BFI wanted to process in Lancaster County. The charges include operating without a permit, transporting the waste in trucks not properly identified as carrying infectious items, and secretly mixing infectious waste with other waste dumped in a landfill.

Some of the more noteworthy examples:

* BFI paid a $200,000 civil penalty after the Louisiana Department of Environmental Quality charged the firm with, among other things, failure to comply with infectious waste handling procedures at Crescent Acres Landfill near New Orleans.

Later, BFI settled for another $280,000 after receiving a separate notice regarding similar problems at Crescent Acres.

* After the Ohio Environmental Protection Agency alleged that a Cleveland infectious waste incinerator failed emissions tests and was operating without a permit, BFI Medical Waste Systems Inc. paid a $28,000 civil penalty. As part of the agreement, BFI closed the facility after it completed construction of a new one in Warren, Ohio.

* A BFI subsidiary, Bio-Medical Services Corp., allegedly started construction at its infectious waste incinerator in Lake City, Ga., before being granted an amended permit. It was slapped with a $25,000 civil penalty.

* Another $25,000 civil penalty resulted from a notice of violation at a BFI subsidiary's medical waste incinerator in Valley Cottage, N.Y., where the New York Department of Environmental Conservation said unmarked and improperly marked trucks _ as well as some not listed on the company's permit _ were transporting infectious waste.

* And at a medical waste autoclave in San Diego, Calif., the company was charged with emitting air contaminants "of such intensity as to create a nuisance." It settled for a $300 fine and a promise to correct the situation.

But medical waste is a relatively new field for the company. In the areas BFI has been involved in longer _ hazardous and solid waste _ the list of charges and violations is more extensive.

The violations listed in BFI's Compliance History include charges by state and federal environmental agencies that the company or its subsidiaries poisoned drinking water, followed unsound testing procedures, and failed to determine what kinds of

waste were going into BFI landfills.

Asbestos, PCBs, cyanide, hydrochloric acid and mercury are among the substances alleged to have been mishandled.

The list is far too long to print in full, but here are a few of the more serious items from BFI's Compliance History:

* At a Williamsburg, Ohio, landfill, BFI pumped 27,000 gallons of toxic waste into the area's drinking water supply, according to the Ohio Attorney General. The BFI subsidiary, CECOS International, pleaded guilty to one violation and was fined $25,000 and court costs. A former CECOS employee was convicted of two misdemeanor and eight felony counts and is now appealing.

In a civil suit about the Williamsburg operation, BFI agreed to a $3.5 million settlement on April 5, 1990, the same day it announced it was selling its hazardous waste business and shutting down the Ohio landfill.

* BFI paid a $200,000 civil penalty for supplying oil contaminated with nitrobenzene (a suspected carcinogen) and cyanide for use on roads in eastern Texas.

The company spent more than a million dollars — the shareholders say $3.5 million — cleaning up roads and establishing a health monitoring system and veterinary referral program.

The government's star witness was a former BFI chemist who blew the whistle and told a Texas newspaper he was fired for it.

* A Livingston, La., landfill cost BFI $2.15 million in a civil penalty after the federal government and the state said they found 2,800 violations there.

* Also in Louisiana, the Willow Springs hazardous waste landfill was the site of 1,400 violations, according to the Environmental Protection Agency. The BFI subsidiary that ran the landfill was subject to a $1.55 million civil penalty.

As of July 1991, when the Compliance History was filed, the federal government was seeking substantially more payments — tens of thousands of dollars a day for each day the violations existed.

BFI says it is fighting the penalties, which it believes are "grossly excessive." The company does "not believe that there exists or have existed any substantive environmental problems at the site," it says in its DER filing.

* BFI was fined $350,000 for violations at its Niagara Falls hazardous waste landfill and denied a permit to expand, forcing it to close. While shutting it down, BFI incurred a $75,000 civil

penalty for allegedly failing to follow procedures aimed at making the closure safe.

* In their lawsuit, shareholders mention one serious instance that does not appear on BFI's Compliance History. They say that the EPA "preliminarily assessed" the waste hauler $14.2 million in March 1991 for illegally dumping PCB-contaminated wastes it received from General Motors.

GM diluted the waste contaminated with the deadly chemical, the shareholders allege, and then solidified it and shipped it to a BFI landfill.

"BFI accepted the PCB-contaminated waste without challenge or inquiry to GM officials, and was therefore fined as an active participant in circumventing the nation's environmental laws," say the shareholders.

BFI is vigorously contesting the charges. Spokesman Block said the $14.2 million figure only represents the maximum the EPA is seeking.

"We weren't assessed a damn thing," he said, adding that what a waste generator does before the waste gets to a landfill "is not our responsibility."

The company responds

What does BFI say about all these violations and fines?

Company spokesman Block says BFI "is a decentralized company in the extreme" but that "the reporting relationship is very close."

"We've placed a lot of emphasis on training managers and then disciplining" those who haven't done their job right, adds Alan P. Magan.

But the shareholders tell a different story in their lawsuit.

Investors Melvin Ronald Cardonick, Michael Koretsky and Sally M. Yeager first filed what they hope will become a class action on behalf of all BFI shareholders last October in Philadelphia federal court.

The case, against the company and various current and former members of its board of directors, has since been transferred to Galveston, Texas, near BFI's Houston headquarters.

BFI has filed technical, legal objections to the suit, seeking to have it thrown out before it goes further. So far, the company hasn't formally challenged the substance of the shareholders'

allegations, however, and both sides are awaiting a ruling from a federal judge about whether the case should go to trial.

The shareholders' allegations are explosive.

At one point in the suit, they say, BFI's leaders "have not only refused to take disciplinary action against the BFI employees ... responsible for the misconduct, waste, and mismanagement complained of herein, but have actually promoted these employees to higher positions within BFI (including election to the Board of Directors) or have paid hundreds of thousands of dollars in 'hush' money to former BFI officials under the guise of 'consultant fees,' all in apparent appreciation of their efforts to not cooperate with the investigating authorities nor implicate their BFI superiors ...."

Far from having an "obsession with compliance" as the company claims in its 1990 annual report, the shareholders say BFI has had a "criminally cavalier attitude" toward the handling of hazardous waste.

To that, Block replies, "You can say anything you want in a lawsuit."

While the shareholders charge "a massive cover-up" has occurred, Block says the company has always been open and forthright about its past problems and that it is working hard to prevent environmental accidents in the future.

Shareholders angry

But the problems BFI has experienced go beyond its ecological record and into the heart of the way the company does business.

BFI's board of directors has "fostered a corporate culture that involves and/or condones criminal and other wrongdoing, waste, and mismanagement at the highest levels of the company," the shareholders claim, citing a disturbing chain of litigation.

Block calls that "nonsense."

But the shareholders in their suit say the company or its officers have engaged in insider trading, consorted with members of the Mafia, and won business through "anticompetitive practices ... reminiscent of those used by robber barons."

If BFI was not able to buy out smaller companies that were competing with it, it undercut their prices, forcing them into bankruptcy in a practice "BFI insiders refer to as 'The Blitz,' " the shareholders allege.

Once BFI had monopolized the market, they allege, it would

raise its prices, "gouging customers at will."

Where Waste Management was the competitor, the two companies sometimes entered into a conspiracy, prosecutors have shown. For instance, in 1980 BFI was indicted for conspiring with other firms including Waste Management "to fix prices and divide, allocate or otherwise apportion customers in the Atlanta area, between 1974 and 1979."

"After BFI and its manager pled (no contest) in connection with the scheme," say the shareholders, "BFI was fined $350,000 and its manager sentenced to one year in prison."

The convicted manager was "subsequently rehired" by BFI after his release from prison, the shareholders state.

BFI also pleaded guilty to price fixing with Waste Management in Toledo, Ohio, in 1987. As a result, the company paid $1 million in fines to the U.S. government and settled with the state for $350,000.

And then there was the Burlington, Vt., trash hauler who said BFI tried to drive him out of business. "Squish him like a bug," a BFI executive instructed company employees, according to testimony in federal court.

In 1989, the Supreme Court upheld a jury's award of $6 million to that trash hauler, Joseph Kelly, and his Kelco Disposal company.

And in a 1981 civil antitrust suit, a BFI competitor alleged that the firm "secretly paid Texas state Sen. Jack Ogg for his assistance in defeating" a landfill application.

Immediately before Ogg was scheduled to testify, BFI settled the case for a reported $5.2 million.

The shareholders allege that the settlement was actually in excess of $20 million and that several of the firm's board members who are still on the board "sought to conceal the full amount from the SEC (Securities and Exchange Commission) and from the investing public generally" by buying the competitor at an inflated price.

What happened to the vice president the shareholders say was responsible for the alleged bribe?

"BFI took no legal or disciplinary action against him," they say. "Rather, ... he was rewarded for his efforts and promoted to chief marketing officer and vice chairman of BFI's board of directors, where he still sits."

BFI spokesman Block freely admits that the company's antitrust record is less than sterling. But he says it is all in the distant

past. The Toledo and Atlanta cases, he points out, involve events that happened in the '70s and early '80s.

"Each of them involved a lot of corporate anguish. Each of them brought about changes in corporate policy," he says. "I will not say that it cannot recur, but I will say that we have taken more forceful steps and provided more comprehensive training."

But the company has found itself in court again more recently on allegations of price-fixing and bid-rigging in its containerized waste business from 1978 to 1987.

In November 1990, BFI agreed to a $30.5 million settlement of a class-action suit filed by customers who accused the company of a nationwide conspiracy with Waste Management Inc., the only waste hauler larger than BFI.

Waste Management agreed to pay $19.5 million to end the litigation, but both companies deny the allegations.

The BFI shareholders further allege a "spate of insider trading by BFI officials."

The shareholders say that R. John Stanton Jr., the company's chief financial officer, and Howard S. Hoover Jr., BFI's general counsel, are targets of an investigation by the Securities and Exchange Commission for insider trading.

Both men have since left the company, following an internal investigation of the charges. The two deny the allegations, says Block, "but they did resign."

The shareholders allege that Stanton sold half his BFI holding three weeks before Sept. 3 when "BFI shocked the investment community by announcing that profits for the 1991 third and fourth quarter would be 15 to 25 percent below those of the same period last year."

The firm's common stock price plummeted 15 percent on the day of the announcement and another 5 percent the day the disclosure was reported in the nation's financial newspapers. So Stanton's timely move saved him $426,600.

Hoover sold half of his 30,000 shares 11 days prior to the announcement, say the shareholders. Had he waited, he would have received nearly $100,000 less.

The shareholders further allege that "BFI was not above submerging itself in the underworld of organized crime" _ a charge the company vigorously denies.

It is a charge that has been repeated for several years. "When

it first began to surface in a serious way," says Block, "we, using the Freedom of Information Act, got 300 pages of reports from the FBI." Many allegations have been made, he said, but every FBI report concludes that there is no proof of such ties.

A 1934 indictment focused on Johnny Pinto, then a vice president of BFI's New Jersey operations.

It charged that Pinto and others "engaged in a 'property rights' system to allocate customers, rigged bids to give the appearance of competition, and used predatory pricing tactics, threats, and even physical force to secure the agreement of other haulers to join and remain in the price-fixing conspiracy," according to the shareholders.

The indictment also alleged that Pinto bribed public officials. He pleaded guilty, according to the lawsuit, and paid $50,000.

Also on BFI's payroll was Ernest Palmieri, "identified in Justice Department reports and Congressional testimony as a leader in the Genovese crime family," the shareholders claim.

According to a publication of the Citizens Clearinghouse for Hazardous Waste, "Harold Kaufman, a former mobster who turned 'state's evidence' ... under the Federal Witness Protection Program" testified before the New York State Assembly in 1984 about BFI.

" 'I don't know anything about BFI in Houston,' " he said, " ' ... but if they play footsies with these guys (known mob figures), knowing full well what is going on, I think they know as much as I do, I think they are cooperating with organized crime.' "

Block says the shareholder's charges are motivated by nothing other than their displeasure with stock prices: "When stock moves either up or down, ... it does bring out this kind of lawsuit."

When asked about the sheer volume of violations listed in the company-compiled "track record" _ the 10-year Compliance History on file at DER _ Magan says:

"Those are violations around the world. That's why it's so long. We don't think our record is unusual ... (considering) we operate 100 landfills, a lot of trucks, transfer stations."

And, like Block, he points out that BFI bought into some of the problems it has had when it purchased landfills from other operators. Also, he admits BFI has had some managers "who haven't done what they are supposed to do."

Block says that situation has been remedied through better training, an emphasis on safety, and the use of an internal audit team that looks for deviations from environmental rules. Plus, he says, managers' bonuses are now tied more closely to compliance with environmental regulations than to profits.

"We have a lot of policies in effect that have teeth in them, and we have a lot of people enforcing those policies," Block adds. "We have tried to create a check-and-balance system."

As for the environment, says Block, "We're pretty particular. The head of this company was twice the head of the EPA, so he has a very high level of concern about not only the environment but about regulations and regulators.

"He has assured that if we weren't paying attention before, we are paying attention now. We were paying attention before, but he has sharpened our focus."

EXH. ___

Price Effects of Landfills on House Values

Arthur C. Nelson, John Genereux, and Michelle Genereux

ABSTRACT. *There is debate on the extent to which landfills impact on nearby single-family homes. This article applies an empirical model to estimate the price effects of one Minnesota landfill on the value of 708 nearby homes during the 1980s. Empirical results indicate that the landfill adversely affected home values in the range of 12 percent at the landfill boundary and 6 percent at about one mile. Beyond about 2–2.5 miles adverse effects are negligible. The findings have important implications for the siting of new landfills near residential areas and in areas within the path of future development.*

I. INTRODUCTION

The effects of certain land uses on residential property values has long been of interest in the public policy arena. Generally speaking, where neighboring or nearby land uses are such that they impose negative price effects on residential property value, nuisance claims are made and sometimes awards are given through the courts or other means. Forms of nuisance can include noise, flies and other insects, hours of operation, traffic, odors, debris located both on the nuisance property and drifting off the property, and appearance. The possibility that some land uses will have negative price effects on residential property drives the land use planning process to physically separate those land uses by such measures as distance, setbacks, and buffering. Sometimes some land uses that are perceived to have negative price effects are banned from the community altogether. In the real estate market people are willing to pay higher prices for sites that are not affected by nuisances than for sites affected by nuisances (Crecine, Davis, and Jackson 1967).

Landfills are commonly considered a form of nuisance. They are places of activity involving trucking, dumping, filling, sorting, spraying, operation of heavy equipment, and noise. In their search for sites for housing, families tend to equate landfill proximity with diminished environmental quality or quality of life. Given a choice between two sites offered for the same price and identical in every respect except that one is closer to a landfill, home buyers will choose the site that is farther away. Only when the closer site is offered for less money will families consider the closer site a suitable alternative. At some lower market price of the closer site, home buyers will become indifferent in choosing between that site and a higher priced one farther away from the landfill.

Literature indicates that environmental features can increase land and house value if they are viewed as attractive or desirable, or they can reduce values if they are viewed as nuisances or undesirable. Ambient noise levels increased by point-sources can reduce nearby urban residential property values (Li and Brown 1980). Air quality reductions associated with point source emissions can reduce nearby residential property value (Ridker and Henning 1967). Urban residential development can reduce nearby agricultural land value (Nelson 1986).

The effect of landfills on residential property values is a subject of debate. Some literature indicates negative effects while other literature indicates positive effects.

Using a sample size of 182 single-family

Nelson is professor, City Planning Program, College of Architecture, School of Public Policy, School of International Affairs, College of Management, Georgia Institute of Technology; Genereux and Genereux are consultants in the social sciences, St. Paul, MN.

homes near five landfills near Fort Wayne, Indiana. Havlicek (1985) found that a house located one mile closer to a landfill than a similar house would be valued about $3,640 less. House price rose about 5 percent per mile away from the landfill.

Adler et al. (1982) studied the price effects of proximity to a hazardous waste site in Pleasant Plains, New Jersey. That operation contaminated local water supplies, a condition which became evident after 1974. Their study evaluated house sales before 1974 (before contamination was known) and after 1974 (when contamination became evident). For homes within 1.5 miles of the landfill, there was no significant change in sales prices before or after 1974, indicating that the landfill impacted prices equally. Between 1.5 miles and 2.25 miles there was about a 10 percent difference in price change between homes sold before and after 1974. For sales after 1974, distance from the landfill was a significant predictor of price effects out to 2.25 miles from the landfill. The mean price effect was found to be $2,700 per mile.[1]

Gamble et al. (1982) evaluated the effects of the large Boyertown Landfill on nearby home values in Montgomery County, Pennsylvania, during the period 1977–79. They limited their investigation to a one mile radius around the landfill, theorizing that home prices farther away would not be substantially affected. While showing that the landfill had a negative effect on property values, the results were not statistically significant perhaps for a variety of reasons.[2] First, they did not include a large enough area away from the landfill to adequately measure variation in house prices that could be attributable to landfill proximity. Second, their sample size was only 137.[3] Third, most cases were grouped near the outer edge of the one mile zone, which means there was only limited variation in the distance variable for this limited set of homes.

In a study done for Browning Ferris, Industries, one of the nation's largest operators of landfills, Research Planning Consultants, Inc. (1983) evaluated price and development effects of landfills on residential properties at four sites located in Houston, Texas, Baltimore, Maryland, Minneapolis, Minnesota, and Atlanta, Georgia. They did not find that landfills imposed negative price effects and, indeed, in some situations they found that landfills actually increased property values and were associated with greater residential development. However, they did not clarify at what stage of the life of the landfills the study was conducted. Near the latter stages of life of a landfill, after property values have already dropped, prices may rise because of future expectations of the positive benefits from closed and covered landfills.

Pettit and Johnson (1987) indicate that where a landfill is located in remote areas, the extension of infrastructure to accommodate the landfill actually attracts residential development towards it. Cartee (1989) concludes that there is little empirical evidence to suggest that landfills impose negative price effects, although he also admonishes that many studies including his own are limited because of a dearth of sales data.

There is, thus, debate on the extent to which landfills impact on nearby single-family homes. This article contributes to that debate. It develops and applies an empirical model to estimate the price effects of one landfill located in Minnesota on the value of more than 700 single-family homes, located within two miles of that landfill, sold during the 1980s. It is the most comprehensive study reported to date on price effects of landfill distance on single-family homes.

II. METHODOLOGY AND APPLICATION

As in any model estimating the price effects on single-family homes of distance to

[1] For sales after 1974, there was no statistical association between value of homes sold inside versus outside of the contamination zone.

[2] Interestingly, the price effect indicated a reduction in value of about $4,200 per mile, or about 5 percent. This is roughly comparable to the effect noted above.

an object causing nuisance or benefit, the model used in this analysis isolates the influence of landfill distance on house price after controlling for attributes of the house, lot, location, and other features:

$$V_i(t) = a_0(t) + \sum_{j=1}^{n} b_j(t)X_{ij}(t) + b_k LF_i = e_i \quad [1]$$

where:

$V_i(t)$ = value of house i at time t;
$X_{ij}(t)$ = contribution of individual attributes to value at time t;
LF_i = distance of the house i from the landfill; and
e_i = error term.

If landfill proximity influences house value negatively, the first-order relationship of house price with respect to distance from landfill is:

$$dLF_i/dV_i(t) > 0 \quad [2]$$

which means that house price rises with respect to distance away from the landfill.

The model is applied to analysis of the single-family house sales price effects of a landfill located in Ramsey, Minnesota. The Anoka Regional Landfill in Ramsey has been accepting solid waste since 1967. It has a permit to allow operations into the 1990s. It receives up to and sometimes more than 500 tons of waste per day. Minnesota state officials have allowed operations to continue and expand. While the area around the landfill was open country when operations commenced, development now comes near the boundary of the landfill.

The Ramsey landfill was selected for a variety of reasons. First, it is set amidst a suburbanizing landscape near a major urban area, Minneapolis–St. Paul. Second, the terrain is relatively flat and lightly wooded. Third, the landfill is operating under substantial regulatory constraints principally aimed at minimizing adverse effects on nearby property value (Genereux 1989). Fourth, the landfill has been operating since 1967 and will continue into the 1990s. The study period for this analysis extends from 1979 through 1989. Fifth, the landfill affects a reasonably homogeneous housing market. This affords reasonable estimation of purely distance effects on house prices where houses are roughly similar across the entire study area.

Data for the analysis come from the Anoka County Property Assessor, the Anoka County Board of Realtor's Multiple Listing Service (MLS), city and county plat maps, city and county highway maps, and site investigations (primarily to assess tree cover on house sites that may block landfill views).

The analysis proceeded in two phases. In the first, the price effect of landfill proximity was estimated by one-half mile increments of concentric zones. This was done to determine at what distance landfill price effects were statistically insignificant. This distance was found to be somewhere between 2.0 and 2.5 miles. The second phase, which is reported here, uses actual distance from the landfill center out two miles. The empirical model developed for this analysis is:

$$\begin{aligned} PRICE_i = a_0 &+ b_1 AGE + b_2 BDRMS \\ &+ b_3 BTHRMS + b_4 DI\text{-}694 \\ &+ b_5 FF + b_6 FIREPL \\ &+ b_7 SMALLLOT + b_8 SALEYR \\ &+ b_9 STYLE20 + b_{10} STYLE50 \\ &+ b_{11} TREES + b_{12} DFILL + w \end{aligned}$$

where

$PRICE_i$ = sales price of house i as reported in the MLS records;
AGE = age of the house in years as indicated in the MLS records;
$BDRMS$ = number of bedrooms as indicated in the MLS records;
$BTHRMS$ = number of bathrooms as indicated in the MLS records;
$DI\text{-}694$ = distance of the center

property i to the nearest interchange with Interstate 694 to the nearest one-twentieth of a mile as measured from city and county maps;

FF = the square feet of the house foundation as measured by the exterior walls (in effect living square feet on the first floor) as indicated in the MLS records;

$FIREPL$ = number of fireplaces (not woodstoves) as indicated in the MLS records;

$SMALLLOT$ = whether the parcel is less than one acre, which is also a proxy for presence of public water and sewer, as indicated in the MLS records (1 if yes, 0 if no), where the lot sizes range between less than one-half acre to less than two acres (larger acreage lots are not evaluated to maintain reasonable homogeneity);

$SALEYR$ = year of transaction as indicated in the MLS records;

$STYLE20$ = whether the house was of two full floors as indicated in the MLS records (1 if yes, 0 if no);

$STYLE50$ = whether the house was of three or more full floors as indicated in the MLS records (1 if yes, 0 if no);

$TREES$ = categorical tree cover where 0 is no cover, 1 is very few, mostly young trees, 2 is several but mostly young trees, 3 is coverage of property by usually immature trees, and 4 is nearly complete tree canopy with mature trees, as determined from windshield surveys (admittedly more subjective than we would have liked);

$DFILL$ = distance of the center of property i to the center of the landfill to the nearest one-twentieth of a mile as measured from city and county maps;

w = stochastic disturbance.

Of principal interest is whether $b_{12} > 0$, which would indicate that the mean property value rises with respect to distance from the landfill. The null hypothesis is that there is no significant association between house price and landfill proximity, all other factors considered.

Ordinary least squares regression is used. It is applied to all 708 sales of houses observed from 1979 through 1989 between 0.35 and 1.95 miles of the center of the landfill. Regression results are reported in Table 1. The descriptive statistics are reported in Table 2. The matrix of correlation coefficients (Pearson correlations) are reported in Table 3. The adjusted coefficient of determination (R^2) is 0.573 and the F-ratio is 80.188 ($p > 0.000$).

The sign on the landfill distance variable is in the expected direction, and the coefficient is significant beyond the 0.01 level of the one-tailed t-test. The magnitude clearly shows that mean house value rises the farther away from the landfill it is, all other factors considered. In particular, house value rises by nearly $5,000 for each mile it is located away from the landfill. On a percentage basis, house value rises by about 6.2 percent per mile from the landfill.

III. IMPLICATIONS

The empirical results indicate that the landfill adversely affects single-family house values in the Ramsey, Minnesota area to a distance of about two miles. Beyond about two miles, there is little if any adverse price effect. This has certain implications for the siting of new landfills. The results also indicated that landfill proximity is associated with a reduction in house value of perhaps more than 12 percent

the landfill boundary and about 6 percent at a distance of about one mile from the landfill boundary.

The analysis is consistent with theoretical expectations and is consistent with many previous empirical studies. Two interesting and important implications emerge. First, this paper demonstrates that at perhaps less than 2.5 miles from the center of a landfill, residential property value will likely be adversely affected. Beyond this distance those effects may not be observed. This has implications for landfill siting around the nation since it confirms reports of other researchers.

Second, within at least two miles, the price effects of landfill proximity on middle income, relatively homogeneous housing markets are such that house value rises about 6 percent per mile from the landfill to about two miles. Work reported here combined with other studies seems to demonstrate this reasonably constant relationship. This reduction in house value is not trivial. A $100,000 home built within one mile of the proposed landfill the day before landfill operations commence would lose $6,000 the day after.

The price effects of landfills on single-family house values estimated from the case studies presented here are common to many other landfills as shown in the literature review. In some instances, landfill operators have realized that nearby property values will suffer because of landfill proximity. For example, Genereux (1989) observed that managers of the Flying Cloud Sanitary Landfill in Eden Prairie, Minnesota, the Anoka Regional Sanitary Landfill in Ramsey, Minnesota, and the Mid-

Landfill near Franklin, Wisconsin, have all purchased land and homes surrounding those facilities in order to avoid, contain, or resolve disputes with private landowners. Browning Ferris Industries included a *compensation in advance* proposal in a 1990 application for a permit to expand capacity at the Flying Cloud Landfill in Eden Prairie, Minnesota.

Caution is made that the analysis does not specifically address the price effects of the latest landfills built and operated pursuant to the most modern standards. Nonetheless, it seems from the analysis reasonable to assume that unless new landfills achieve a state of operations such that the urban housing markets view them as essentially benign, one should expect that landfills will have negative price effects.

Stigma, environmental risk and property value: 10 critical inquiries.

Richard Roddewig

Over the past two decades, real estate appraisers have gained considerable experience in valuing property affected by environmental risk. In fact, many in the appraisal community are now so comfortable analyzing those impacts on property markets and market values that some now specialize in environmental risk analysis. The increased comfort level of both the marketplace and appraisers with this type of analysis is, in part, a result of improved techniques for environmental assessment, wider availability of data about the numbers, types and locations of properties likely to be affected by environmental risks, better information about health risks posed by some environmental conditions,and enhancements in removal/remediation techniques. The simple passage of time has also helped. It has allowed real estate owners, developers, lenders, buyers, sellers, and appraisers to become familiar with processes for the appropriate analysis of the potential impact of environmental risks on property.

The Appraisal Institute and its predecessor organizations have been instrumental in this process as well. For example, since 1985, The Appraisal Journal has published at least 70 articles dealing with environmental topics.(1) In addition, the Appraisal Institute launched a new publication called Environmental Watch in 1988. This newsletter concentrated on environmental issues pertinent to appraisers.(2) In 1989, the American Institute of Real Estate Appraisers adopted Guide Note 8 which dealt with "The Consideration of Hazardous Substances in the Appraisal Process." That note was adopted in 1991 in its entirety by the Appraisal Institute. In 1992, the Appraisal Institute Board of Directors appointed a special Appraisers' Environmental Responsibility Task Force that subsequently promulgated a voluntary Property Observation Checklist, which appraisers may use when inspecting property likely to be affected by environmental risks. In 1993 the Appraisal Institute published a video titled Hidden Factors: Environmental Risks and the Real Estate Appraiser, that gives special attention to the environmental site assessment process. In 1994, the Appraisal Institute introduced a new seminar titled "Environmental Risk and the Real Estate Appraisal Process," which has been taught in many locations across the country. The essence of many of the articles published in The Appraisal Journal and Environmental Watch, and the information in the Hidden Risks video, and the seminar course can be distilled to 10 critical inquiries that every real estate appraiser should bear in mind in assignments involving contaminated properties.

STIGMA AND ENVIRONMENTAL RISK: WHAT ARE THEY?

The concept of environmental risk as applied to real estate is broad and covers a range of substances, events and land use activities. We may typically think of environmental risk as emanating from such things as groundwater contamination or soil contamination by hazardous substances. But it can be generated in many other ways as well, for example, by air pollution or movement of airborne contaminants on the wind, by pollution of lakes or streams, by contamination of drinking water distribution systems, or even by noise such as might emanate from a busy expressway or an airport. An event, such as a marine oil spill or a railroad derailment involving tank cars carrying chemicals, may create temporary environmental risks until cleanup is completed. Also, certain types of land uses, such as power plants, electrical transmission lines, landfills, waste incinerators, chemical or radioactive material storage facilities, may be perceived in some locations as creating environmental risk for adjacent or nearby real estate.

In analyzing environmental risk, however, real estate appraisers must carefully bear in mind the following points. Not every use of a hazardous substance results in contamination. Not every use of a hazardous substance that does result in contamination necessarily creates an environmental risk. And not every use of a hazardous substance that results in contamination and results in environmental impact and environmental risk necessarily results in a real estate market impact.(3)

The Appraisal Institute emphasizes that environmental risk should be evaluated in the context of a system. The substance itself may be a big part of the risk, but the amount of real estate impact, if any, depends on many other systemic factors such as how the substance is controlled, how it is spread, how many people are potentially affected by the risk, and the degree to which people may be affected.(4)

Stigma, as it applies to real estate affected by environmental risk, is generally defined as "an adverse public perception about a property that is intangible or not directly quantifiable."(5) It is an additional impact on value, over and above the cost of cleanup or remediation. Stigma can occur on sites that once contained contaminants and have been cleaned up, on sites undergoing cleanup, or on sites that were never contaminated but neighbor a property that contains or once contained contaminants.

In many appraisal assignments, the costs of cleanup or remediation are known or have been reasonably quantified by technical environmental assessment specialists. The appraiser's

principal task may be to provide an opinion of the additional impact, if any, arising from the "stigma" associated with the site in the marketplace before, during, or after the cleanup process.

QUESTION 1: WHAT TYPE OF RISK OR CONTAMINATION IS PRESENT?

Not every contaminant or hazardous substance creates the same level of health risk. And not every contaminant creates the same level of risk of impact on property values or markets. Therefore, for the appraiser to do his or her job effectively, the character of the contaminant and its technical environmental impacts. and potential health impacts should be understood.

What types of information about the substance should the appraiser obtain in order to understand the real estate impact risks? They can be summarized as follows: the most likely locations, typical transport media, typical transport mechanisms, types of environmental impact and potential health effects, and accepted remediation techniques.

An appraiser needs to know about the typical or most common sources of the substance or risk. Are they widespread or localized? Are the locations well known and carefully documented, or of uncertain extent? How does the substance get into the environment? Does it get into soil, air, groundwater, surface water? Does it get into the food chain? Does it result from natural processes, such as with radon emissions? Or does it get into the environment only as a result of human processes, such as with PCBs?

How does it move through the environment? For example, is it transported by erosion, water, air currents, human or animal activities? The speed at which it moves and the distance it can travel can be affected by such factors as topography, soil type, geology, hydrology, or even wind and air patterns. How do such factors as temperature and humidity affect its movement and presence?

What are the known or suspected impacts on human health? Is the substance a known carcinogen or only suspected of contributing to cancer? How conclusive is the scientific evidence about the link between the substance and health impacts? At what stage is the research on the health effects? These are all things an appraiser may need to know something about because they may be at the core of the real estate marketplace reaction to owning property containing or affected by proximity to the substance or risk.

Knowledge of the appropriate remediation techniques is also crucial to the appraiser's inquiries. Some substances and risks can be easily controlled or remediated, while others cannot. Remediation techniques may include physical removal, on-site treatment, or encapsulation. On-site treatment techniques may vary depending on the nature of the substance, the degree of

contamination, or the media in which the substance is located, such as in groundwater or soil. Appropriate remediation techniques may vary from one substance or risk to another. For example, physical removal of some substances, like PCBs, may be the only appropriate technique while on-site encapsulation is appropriate for others like urea-formaldehyde insulation or some types of asbestos.

QUESTION 2: HOW DO THE FIVE CRITICAL CYCLES AFFECT PERCEPTIONS OF THE RISK?

Every appraiser experienced with evaluating environmental risks soon notices discernible stages in the market concern about environmental impacts of any particular substance. To understand how this works, consider the history of the concern about asbestos as a hazardous substance. Asbestos was widely used in the construction industry in the 1950s and 1960s. Use grew substantially in the early 1970s as well until studies began to conclusively document that asbestos fibers could get into the lungs and cause asbestosis, a potentially fatal condition. Between 1972 and 1975, the Environmental Protection Agency (EPA) issued a series of regulations about the use of asbestos, in many cases banning its use in construction.

Newspapers in the early 1970s had extensive coverage of the asbestos health risks,(6) causing near panic in some sectors of the real estate marketplace. Many properties containing asbestos were stigmatized, becoming unmarketable virtually overnight when many major lenders and financial institutions adopted policies against lending on any property containing asbestos, and some prospective tenants adopted policies against leasing in buildings containing asbestos.(7) By the early 1990s, however, the situation was completely changed. Buildings in which asbestos had been removed, and even buildings with asbestos in place, were routinely bought and sold in the marketplace, and most lenders and tenants were quite comfortable in evaluating the risks.

What happened in the intervening 20 years that so dramatically changed the situation? The marketplace simply got more comfortable in evaluating the risks associated with ownership of a building containing or once containing asbestos. This naturally occurred as a result of the normal evolution of five critical cycles that affect the market for properties affected by environmental risk: the health risk cycle, the remediation cycle, the public relations (media) cycle, the regulatory cycle, and the lending cycle. All of these five cycles are interrelated. In fact, they may more properly be considered as part of one larger systemic cycle that repeats itself over and over again with each new substance or environmental risk that gets attention in the real estate marketplace. To evaluate the impact of environmental risk on real estate, the appraiser needs to understand each component and how the five cycles fit into a larger pattern.

The Health Risk Cycle

The health risk cycle typically begins with the publication of a groundbreaking study linking some common substance in the environment with a health effect. This initial study typically finds some correlation between the substance and a serious disease or condition, often an increased incidence of cancer in persons exposed to the substance. Appearance of the first study typically begets additional studies showing the same effects or focuses attention on other earlier studies showing the same results.

Soon, however, a scientific dialogue emerges, as additional studies critically evaluate the results of the initial studies, poke holes in the methodology, or refine the analysis to better clarify the situations in which health impacts may or may not be likely. This is typically accompanied by better measurement and understanding of the concentrations necessary to create health risks, better data about the locations of sources of the substance, and information on simple ways to limit exposure to the contaminant.

With most of the significant environmental risks that have initially been considered to have widespread impacts on the real estate marketplace in recent years - consider asbestos, PCBs, radon, and electromagnetic fields, for example - the result has been the same: As more scientific information becomes available, general alarm and concern in the real estate community abates and becomes more narrowly focused on a smaller pool of properties than first suspected.

The Remediation Cycle

Once the potential health risk posed by a substance becomes a factor in the real estate marketplace, the real estate community immediately begins to seek information about techniques to remediate or lessen the risk. One reason why a marketplace may shut down, as it did in the wake of early concerns about asbestos in commercial buildings, is due to lack of information about types and costs of remediation techniques. As time passes, however, if the market gets more information about remediation, the stigma typically decreases.

Attention given to developing remediation techniques is often directly proportional to the perceived magnitude of the health risks and the number of properties potentially affected by the environmental risk. Remediation techniques are proposed, evaluated, and tested. Results of the tests are publicized, leading to further refinements. A remediation "industry" may actually develop to apply appropriate techniques to the problem properties. Initially, remediation costs may be high, but as more research is done, and more competitors for remediation business enter the marketplace, the cost of remediation is driven down. Eventually, the real estate marketplace becomes more comfortable with its ability to estimate

remediation costs for particular types of environmental risks in a variety of settings. Over time, that often means a decrease in the component of stigma caused by uncertainty about remediation techniques and costs.

The Public Relations (Media) Cycle

The old conundrum about falling trees, noise, and human ears applies to the publication of articles about the health effects of substances commonly found in the environment. If it is published only in the scientific or technical literature, and gets no mention in the popular press or at least in professional real estate publications, the substance may have little effect on real estate markets.

Consider the recent concern about the impact of electromagnetic fields emitted by power lines on property values. The first U.S. epidemiological study showing a possible relationship between power lines and some forms of cancer was published in 1979.(8) It was not until a decade later that this study received serious attention. This was the result of an article published in The New Yorker magazine by an author whose book, published a year later, put the issue before the general public for the first time.(9)

The popular media treatment of environmental risks typically runs in three phases. In the first phase of the cycle, there is extensive newspaper and electronic media reporting of studies asserting some adverse health effect associated with a substance, building material, or land use previously perceived by the public as being of no environmental concern. This first phase of the cycle also typically involves allegations that the substance, material, or land use creates a widespread risk of serious magnitude, and includes interviews with concerned citizens and environmental groups emphasizing possible dangers from exposure. As the first phase continues, government authorities promise investigation and response, and promise new regulations, if necessary, to lessen the risk.

The second phase of the cycle typically begins with the publication of information on ways of avoiding, remediating, ameliorating, or limiting exposure to the potential problem, publication of additional studies indicating that the health effects are not as conclusive or as serious as first reported, or at least not likely to be as widespread or occur as frequently as first suspected.

In the second phase also, the media begin to report on technologies and techniques for control, cleanup, remediation, or avoidance of the risk. As this information becomes more widely available, the costs associated with the techniques become better understood and more easily quantifiable. Information also becomes

available about the situations in which the risks are likely to be high and those in which exposure or proximity to the risk is limited. Much of the information resulting from this second phase comes as a result of the government process of investigating the existence and seriousness of the risk and determining if there is any need for new regulation of the causes.

In the third phase of the cycle, the market has completely digested the information and makes more informed decisions about the level of risk, if any, and the costs of avoiding or ameliorating it. In this third phase, initial perceptions about potential impacts may be greatly diminished. When the potential impacts relate to property values, the concerns of the marketplace about the number and type of properties potentially affected may also be greatly reduced. And with respect to some types of risks, the market may no longer perceive any adverse impact on property values.

The Regulatory Cycle

There is also a cycle in the way regulators and lawmakers respond to public concerns about possible environmental risks. It typically follows the same pattern as the three phases of the media cycle. In the first phase, lawmakers and regulators respond with cries of concern and alarm, and promises to investigate and "do something" about the problem, if there is one. In the second phase, they launch investigations of the problem, and perhaps hold public hearings to determine its seriousness and garner different points of view. Regulators publish technical studies and propose new regulations or improved laws to control the problem. In the third phase, the new laws are put into practice and then monitored to determine if they are having the intended effect, or whether the laws themselves are creating unforeseen problems and need to be adjusted.

If the laws enacted are very strict, they may have unintended consequences. That is exactly what has happened as a result of some of the Superfund program and the state programs modeled on it. In some older industrial areas, so-called "brown-fields," so many properties have contamination problems that qualify or potentially qualify for federal or state Superfund programs, that the real estate market, in some cases, has virtually evaporated. In other markets, it simply creates further impetus for suburban rather than inner-city development. Federal and state regulators are now trying to modify and streamline regulations in order to eliminate some of these regulatory impediments to sale and redevelopment, now reversing past trends for ever-tighter environmental regulations.

The Lending Cycle

The lending community has also gone through a cycle in the way it has reacted to environmental risk, and now has institutionalized

and regularized its procedures for dealing with those risks. In the early 1980s, lenders were so nervous about environmental risk and the real estate marketplace that even the hint of a contamination problem might cause entire categories of properties to be unmortgageable.

That attitude has changed dramatically. Lenders have become more comfortable in evaluating environmental risks. Some of this is the result of the institutionalization of the environmental site assessment process as part of customary mortgage lending practice. Some of it is the result of changes in laws and regulations that clarify when mortgage lenders are, and are not, responsible for cleanup costs. Some of it results from the Federal Deposit Insurance Corporation (FDIC) guidelines issued in February 1993, outlining the steps that member banks should take to implement a proper program for analysis of environmental risk.(10) One of the recommendations of the FDIC is that every institution should appoint a designated senior officer to be responsible for environmental program implementation. Some of it is the simple result of lenders gaining more knowledge about comparative risks created by various environmental conditions.

QUESTION 3: HAS THERE BEEN AN ENVIRONMENTAL SITE ASSESSMENT?

Thanks to the cycle that has occurred in the lending community, a new industry in environmental site assessment has developed since 1986. Most major lenders now routinely insist on some kind of environmental analysis on commercial properties before making a loan, and the standard Uniform Residential Appraisal Report (URAR) form specifically requires an appraiser to comment on "adverse environmental conditions (such as, but not limited to, hazardous wastes, toxic substances, etc.) present in the improvements, on the site, or in the immediate vicinity of the subject property."(11)

The purpose of the analysis is to gather as much information as possible about existing or potential environmental conditions that might affect value and the security of the mortgage loan. Site assessments are undertaken in stages, typically known as Phase I, Phase II, and Phase III site assessments. Phase I assessments usually consist of four areas of research and inquiry: (1) interviews with current owners/operators and inspection of owner or operator documents and records; (2) search of the chain of title for any evidence that past owners, operators, or tenants undertook activities that might have resulted in discharges of contamination; (3) inquiry to government agencies for information about past discharges or storage of potential contaminants on site or nearby; and (4) actual onsite inspection.

If the Phase I work results in some evidence of possible surface or subsurface contamination or past or present violations of environmental laws and regulations, a Phase II assessment may be

undertaken. The purpose of this second phase is to confirm the presence or absence of contamination, and document the types, amounts and locations, and possible rates of migration through soil or groundwater. Soil testing and even groundwater testing may be undertaken during the Phase II investigation. Following completion of the Phase II assessment, there may be a Phase III assessment that further analyzes the site and better defines the amount, location, and control or cleanup techniques and costs.

The information gathered in the environmental site assessment process can be very significant to the potential mortgage lender, the real estate marketplace, and therefore the appraiser in estimating value. The site assessment process pinpoints the location and amount of any contaminants, and, if it proceeds into a Phase II or Phase III assessment, the appropriate control or remediation techniques and their costs. The availability of accurate information about the levels of contamination and the costs and duration of control or cleanup can cut down dramatically on the risk associated with ownership of property affected by environmental risk.

QUESTION 4: IS IT A DESIGNATED FEDERAL OR STATE SUPERFUND SITE?

The federal program known as "Superfund" was established by the Comprehensive Environmental Response, Compensation and Liability Act of 1980, known better by its acronym, CERCLA.(12) The principal focus of the program is to identify abandoned and inactive hazardous waste sites and stimulate their cleanup. The Super-fund itself is the pot of money appropriated by Congress to clean up specifically designated sites.

As of the end of 1994, just over 38,000 sites all over the country had been brought into the program. However, only about 1,300 of these sites are actual Superfund sites with cleanup programs in process. These 1,300 properties are on the National Priority List (NPL), and have been selected from the larger group of sites based on a scoring system that evaluates many factors, including relative toxicity of substances on site, location, size of the population at risk, potential for groundwater contamination or drinking water contamination, and potential threat to air quality. The larger database from which NPL sites is drawn is called the Comprehensive Environmental Response, Compensation and Liability Information System (CERCLIS). Qualifying sites can be brought to the attention of the EPA in many ways, including as a result of actual government monitoring of reported releases of hazardous substances at the site, citizen complaints, or government investigations.(13)

Inclusion of a property in either the CERCLIS or NPL lists can often have significant consequences for the value of the property and even the value of adjacent properties.(14) The principal reason

is that the EPA can undertake a remedial cleanup plan and hold current or past owners or operators of NPL sites liable for reimbursement of those cleanup costs.(15) A current or past owner or operator can be liable whether or not it had any involvement in the handling, disposal, or treatment of the hazardous substance on the site.(16) And because cleanup responsibility is "joint and several," each current or former owner or operator can be held liable for the entire costs of cleanup. That means the owner or operator with the deepest pockets is often the one pursued hardest, even when that entity made no contribution to the problem.

Those factors by themselves might be enough to create significant market stigma for many Superfund sites. But there is another reason also. Lenders are extremely reluctant to make a loan on a site that is or potentially could be part of the Superfund program because as the law is currently being applied by the courts, in some circumstances a lender can be declared to be an owner or operator - and therefore a party potentially responsible for cleanup - even in the absence of a foreclosure action.(17)

One way a buyer or prospective operator of a site included in the CERCLA program can avoid liability for cleanup costs is to meet the legal definition of an "innocent landowner."(18) That exception is available when an owner did not know at the time of purchase, or had no reason to know, that hazardous substances were on the property. The proof is evidence that before the purchase the buyer made all reasonable inquiries consistent with good commercial or customary practice, thus, the impetus for Phase I and Phase II environmental assessments.

At least 35 states(19) have adopted their own programs modeled on the federal Superfund concept. Some states may have their own equivalent of the CERCLIS list, the scoring system, and the NPL list of properties with the highest priority for cleanup.(20) Also, many of these properties may not otherwise qualify for the federal Superfund program. State listing too may create responsibilities for cleanup, with the same kind of joint and several "no fault" liability.(21)

All of this means, however, that an appraiser should carefully evaluate the potential for a property to be part of the Superfund program. Information about existing properties on the CERCLIS or NPL lists can be obtained from regional offices of the EPA. It may even provide maps. State environmental protection agencies can also provide information on either federal or state equivalent listings.

But the regulatory environment is changing quickly. Early in 1995, the EPA removed about 25,000 sites from CERCLIS. These were generally sites that had been investigated by the EPA and found no longer to be of federal interest either because they were found to contain no or little contamination or were being cleaned up under state programs. The intention was to remove some of the stigma that

accompanies inclusion in CERCLIS, and encourage more sale and redevelopment of brownfields, which are typically in the Northeast and Midwest. And Congress has before it a number of legislative initiatives that would clarify and limit the responsibility of lenders for cleanup, help identify portions of contaminated sites that do not require cleanup, and match the appropriate remediation technique to "reasonably expected future land uses at sites."(22) All of these pending changes may, in the future, reduce the amount of stigma associated with Superfund site listing.

QUESTION 5: IS THERE AN APPROVED OR COMPLETED REMEDIATION PLAN?

There are many different types of control and cleanup techniques and methods. In fact, there are many different definitions of the word "remediation." It can have a technical, legal term that can carefully differentiate some types of control or cleanup activities from others, for example, by differentiating a "remedial action" from a "removal action."(23)

Under Superfund and its state-level surrogates, a federal or state environmental protection agency typically undertakes a remedial investigation and feasibility study to determine type of contamination, extent, possible cleanup technologies and options, and likely costs. The same kind of investigation is undertaken in some other types of environmental programs, for example, under state programs requiring removal of underground storage tanks.(24) A common element in these types of programs is that a federal, state or local agency with environmental responsibility eventually approves a plan for action to lessen the risk of a release of a contaminant or assure cleanup to an appropriate standard.

The approval of such a plan, therefore, can eliminate some of the environmental risk associated with owning a contaminated site. The basis of the action plan is a site investigation. The testing and monitoring provides data about the nature and extent of the problem that allows selection of the appropriate technology for cleanup and a quantification of the cost. But most importantly, approval of the plan by a government agency often defines the legal cleanup responsibility of parties involved with the property and the cleanup attainment standard that must be met. All of that narrows risk.

As part of this inquiry the appraiser should ask the following questions:

* Is there an approved remediation plan?

* Who has approved it and how?

* How certain is the remediation approval?

* Is there any risk of additional remediation being ordered

after completion?

* What is the approved remediation technique?

* How long will the remediation process take?

* What will be the level of cleanup after remediation?

* Does the remediation require ongoing monitoring? If so, for how long, and who pays for monitoring costs?

* What will the remediation cost?

* Who will pay the cost of remediation?

Is there a federal or state program to reimburse for remediation costs?

QUESTION 6: HOW DOES THE CONTAMINATION AFFECT CURRENT USE?

Some uses may be more affected by contamination or environmental risk than others. For example, a use that sits above a contaminated aquifer and needs unpolluted groundwater for on-site drinking water may be more affected than a use on the same site that does not need to use the groundwater.

So the appraiser has to undertake a highest and best use analysis, taking into account the presence of the environmental risk. A careful analysis should be undertaken to determine if the current use has, in any way, been affected by the risk. If it has not been affected, and the current use is the highest and best use and is likely to continue indefinitely, then many times there may be little or no stigma from the contamination or risk.

Sometimes, for example, in litigation, the appraiser may be asked to consider the highest and best use of the property both before and after considering the environmental risk. In some situations, the current use may not be the highest and best use of the property when the value of the property is considered free and clear of the contamination. However, an analysis of the past operations of the current use may indicate that it can continue indefinitely even with the contamination in place. If so, there may be some continuing use of the property after considering the contamination, and that use may indeed be the highest and best use.

QUESTION 7: HOW DOES THE CONTAMINATION AFFECT SURROUNDING USES?

This inquiry may be important in two contexts. First, the appraiser may be valuing property adjacent to a source of potential contamination or risk, for example, property next to a landfill or adjacent to overhead transmission lines or a service station with

a leaking underground storage tank. Second, the appraiser may be valuing the property that is itself the source of potential contamination or risk, but trying to determine the implications of actual or possible off-site migration or transmission on the value of the source property.

In either context, perceptions in the marketplace may be as important as the reality of whether the contamination or substance is actually physically affecting surrounding property. But the appraiser must take care to determine real market impacts on adjacent property from mere allegations of market impact. The appraiser's job is to investigate the market for evidence that indicates an impact on value, and if so, how far the off-site impact extends.

The starting point for the inquiry is usually the factual basis of any off-site migration or physical effects. What do the technical assessments and off-site testing show about the actual location and intensity of off-site impacts? Does the extent of the off-site migration vary, depending on such factors as soil conditions, slopes, wind patterns, etc.? How have local governments with land use and zoning authority responded? Have they imposed, or are they likely to impose in the future, development moratoria, limitations on use, special hearing requirements, or other land use regulations around the source of the risk?

Many types of uses, such as sanitary landfills, power plants, transmission lines, airports, expressways, and hazardous waste sites have been studied in a variety of settings to determine their off-site impacts, if any.(25) The appraiser may be able to use these other case studies as evidence of the actual or potential impact of similar uses in other settings. Care must be taken, however, to make adjustments as appropriate when considering case studies from other locations or based on past events or different contamination or risk situations.

Actual or potential impact on surrounding uses may affect the value of the source property. The risk of owning the property that is the source of the contamination may be increased if there is the possibility of impact on surrounding properties as well.

QUESTION 8: ARE THERE GOVERNMENT PROGRAMS TO OFFSET RISKS?

Many states have been assisting the private sector in cleaning up contaminated properties. Other states have been trying to limit the exposure of property owners to damage claims as a way of encouraging the redevelopment of older industrial areas. These programs, when effective, can go a long way to offsetting the risk associated with owning some types of properties affected by environmental risk.

For some types of environmental cleanup, there is special

state funding available to reimburse cleanup expenditures. This is most frequently available for the removal of leaking underground storage tanks and the remediation of soil or groundwater contamination problems that may have resulted. Often "Petrofund" programs, they are typically paid for by a special tax on gasoline sales,(26) and may go far to offsetting the impact of environmental risk on the value of the properties that qualify for the program.(27)

In some states, regulatory agencies will issue various "letters" to relieve property owners of their anxiety regarding environmental risk on their properties. Among the types of letters are the "no action" letters, which are intended to assure future buyers that once a plan for cleanup has been approved, no further cleanup actions will be required. "No association" or "good neighbor" letters state that if an owner did not cause the original contamination and has voluntarily undertaken approved testing and cleanup on the property, there is no liability for further cleanup.(28)

The EPA has a number of programs in the works to "help remove the barriers to property transfer and revitalization"(29) of contaminated sites in the CERCLIS and NPL programs. These are the so-called brownfield initiatives, designed to encourage the reuse of older contaminated, manufacturing sites in major urban areas. As a result of one of the initiatives, the EPA has promised to develop "guidance" to "reassure lenders and prospective purchasers of the safety of their investments, and to thereby encourage the cleanup and redevelopment of contaminated properties."(30) As these brown field initiatives develop, the perceptions of risk associated with actual or potential Superfund listing may be significantly reduced for some properties.

QUESTION 9: ARE THERE GUARANTEE OR INSURANCE PROGRAMS FOR BUYERS?

With some types of environmental risks, it has become quite common for property owners to provide an indemnity to purchasers and even neighbors against liability for future cleanup costs and other potential impacts of the contamination. This has become quite common, for example, when major oil companies sell service station/convenience store sites. It also has become common practice among major landfill operators to provide property value guarantee programs as part of the process of seeking government approval for expansion or construction of landfills.(31)

Such a guarantee program can offset some or all of the stigma risk associated with owning a previously contaminated property, or owning a property adjacent to a source of environmental risk. There are some critical questions that the appraiser should ask about the guarantee or indemnity, including the following:

* What does the guarantee cover? Are all cleanup costs, including testing, monitoring and consultants fees covered? Are only future cleanup costs covered, or are other types of impacts such as potential stigma impact on value also covered?

* How long does the guarantee run?

* Does it extend to third parties, such as future owners and tenants?

* What is the credit rating of the company providing the guarantee? Is it a large national concern with significant assets?

* Is the guarantee structured to survive merger, sale, or acquisition of the company?

* What is the track record of the guarantor? Do they stand behind their promises? Do they cooperate when claims are made for indemnification on environmental risk guarantees?

Availability of environmental insurance should also be explored by the appraiser. True "environmental impairment liability" policies are available to provide site-specific coverage for some types of land uses that may create environmental risks, for example, landfills, hazardous waste storage and treatment facilities, and manufacturing sites where potential pollutants are used in or produced as a by-product of the manufacturing process.(32) These policies generally provide third-party, bodily injury and property damage coverage for loss, along with cleanup costs and legal expenses generated by pollution accidents.(33) Policy premiums can be expensive - $200,000 per year for simple third-person property damage and bodily injury coverage to $2.0 million or more for facilities that produce or store vast quantities of potential pollutants. As new insurers enter the marketplace, premium costs are expected to decrease substantially.(34) An appraiser's job is to observe the marketplace's response to the availability of such insurance programs. If the marketplace begins to consider it a standard operating expense item for certain types of property, then an appraiser may have to make an adjustment to operating expenses or to market value to reflect the costs. That may, in turn, affect the appropriate capitalization or discount rate on income-producing property.

QUESTION 10: HOW GOOD ARE THE "COMPARABLE" SALES?

As the appraisal profession becomes more comfortable with valuation of properties affected by environmental risk, it is developing a better database of sales transactions and market studies involving property affected by environmental risk. This sales information is typically collected by appraisers in one of four ways:

* From inquiries to appraisers who specialize in valuation of properties affected by environmental risk

* As a result of a notice in the Appraisal Institute's newsletter, Appraiser News,(35) requesting sales or other market data involving a particular risk

* From independent research into contaminated property sales, beginning with data about properties included in various federal or state lists of contaminated properties

Even the best sales information about properties affected by environmental risk obtained from a reliable source may not fit the standard definition of a comparable sale. The appraisal profession typically thinks of a comparable as property similar in many respects to the property being appraised. Often, the best the appraiser may be able to do when evaluating stigma impact of environmental risk is to find sales of other property affected by a different type or intensity of contaminant, in a different location, and for a different use. Is that a comparable? Probably not in the strict definition of the term. Nevertheless, it may be quite helpful in arriving at an opinion on the impact of stigma on value. It should properly be considered as a case study rather than a comparable sale.

When collecting sales information from other appraisers about stigma-affected properties, it is more important than ever to verify the accuracy of the information. Valuation of property affected by environmental risk is such a new area of appraisal practice that the thoroughness of data collection practices vary considerably from one appraiser to another.

As part of the evaluation of the comparable sale or case study, the appraiser may have to compare and contrast that sale with the property being appraised on many points that might affect the appraiser's conclusion regarding the amount of stigma, including the following factors:

* Type of environmental risk, contamination or event creating potential for stigma, including comparison on such points as toxicity, persistence, amount or physical extent of contamination (for example, on-site or off-site migration)

* Regulatory framework affecting the risk or substance

* Physical characteristics of the site

* Amount and quality of the testing, assessment, and monitoring (meaning the extent and reasonable accuracy of the data)

* Type and level of cleanup

* Date of sale, especially considering the importance of the five cycles

* Location

* Media coverage

* Conditions of the sale, including availability of an indemnity or insurance program

* Use of the property

* Motivations of buyers and sellers

* Lenders' attitudes

CONCLUSION

It is not enough for an appraiser today simply to conclude that if a property is contaminated, there is no market for it. That may still be true for some types of properties, but the number of such totally stigmatized properties is relatively small. It is also not good enough for the appraiser to expect that he or she will always be able to assume away the presence of the contamination and appraise the property as if unaffected by environmental risk. While there may still be times when such an approach is absolutely the right thing to do, more and more users of appraisal services want answers to tough questions about the actual impact, if any, of specific types of environmental risk on property values, and will go to another vendor of appraisal services if their usual appraiser rejects the assignment.

But in valuing property affected by environmental risk, appraisers have to be ever alert to the nuances of the marketplace. Our job, as always, is to look to the marketplace to see how it actually prices property and determines value. As the marketplace adjusts to risks and prices the real estate product to reflect changing perceptions, so too must old appraisal theory give way to new professional practice techniques that incorporate those changes in the marketplace.

That is especially true today in the rapidly changing practice area involving contaminated properties and other forms of real estate affected by environmental risk. The appraiser's job is to ask the right questions and then listen to the market as it reveals its reasons for acting the way it does. Only if the appraiser does that can he or she gain enough understanding of the market to apply that knowledge to other appraisal situations correctly.

13. 42 U.S.C., sec. 9603(a) and (c), 9604(b), 9659(a).

14. According to EPA administrator Carol M. Browner, "The mere fact that these sites have remained in CERCLIS has caused potential developers to shy away from them and many lending and real estate investment communities have denied loans for businesses in or near CERCLIS sites as a matter of policy." Statement of Carol M. Browner, Administrator, U.S. Environmental Protection Agency before the Commerce, Trade, and Hazardous Materials Subcommittee, Committee on Commerce, U.S. House of Representatives, March 16, 1995.

15. EPA's policy is not to seek cleanup costs from residential property owners unless those owners caused the contamination. See Policy Towards Owners of Residential Property at Superfund Sites, OSWER Directive No. 9834.6, July 3, 1991.

16. Most courts have found an exception for state government. See, for example, United States v. Dart Indus., Inc., 847 F.2d 144 (4th Cir. 1988).

17. When CERCLA was first adopted, lenders thought they were exempted from the strict liability rule for cleanup. However, a series of court cases, culminating in United States v. Fleet Factors Corp., 724 F.Supp. 955 (S.D. Ga. 1988), 901 F.2d 1550, reh'g denied, en banc, 911 F.2d 742 (11th Cir. 1990), held that in some limited circumstances, a mortgage lender could be held to be an "operator" and therefore potentially liable for cleanup costs. In the wake of the Fleet Factors decision, the U.S. EPA, at the urging of the lending community, adopted a regulation that specifically exempted lenders from strict liability for cleanup. However, that regulation was eventually struck down by the courts on the basis that it exceeded the agency's rulemaking authority.

18.42 U.S.C., sec. 9607(b)(3).

19. The following states either do not have their own Superfund legislation, or have more limited legislation: Alabama; Connecticut (state only has authority to act under CERCLA and has no independent state provision); Washington, D.C.; Georgia; Nebraska; Nevada (very limited CERCLA-like provisions); Ohio (state has no independent liability provisions); Rhode Island (no clear liability standards of its own); South Dakota; West Virginia (no liability provision of its own); Wisconsin (limited CERCLA-like provisions); and Wyoming.

20. See, for example, Wisconsin Stat. Ann., sec, 144.442(4), and Utah Code Ann., sec. 19-6-311.

21. See, for example, New Jersey Stat. Ann., sec. 58.10-23.11g(c); Or. Rev. Stat., sec. 466.567 and 466.640; and Pennsylvania Stat. Ann., sec. 60320.702.

22. See, generally, the testimony of Carol Browner, supra.

23."Remedial action" has been defined, in part, as follows: "Those actions consistent with permanent remedy taken instead of, or in addition to, removal action in the event of a release or threatened release of a hazardous substance into the environment, to prevent or minimize the release of hazardous substances so that they do not migrate to cause substantial danger to present or future public health or welfare or the environment."
"Removal action" has been defined as follows: "Short-term immediate actions taken to address releases of hazardous substances that require expedited response." See Thomas F. P. Sullivan, ed., Environmental Regulatory Glossary, 6th ed. (Rockville, Maryland: Government Institutes, Inc., 1093): 469-471.

24. See, for example, Florida Stat. Ann. Ch. 376-3071(5).

25. For a good summary of many of these studies and articles, see Environmental Risk and the Real Estate Appraisal Process, Addenda N and O.

26. See generally, Nebraska Rev. Stat., sec. 81-15 and Wisconsin Stat. Ann., sec. 101.43.

27. In some states, there may be limits on the amount of money that can be allocated to any one particular site. For example, in Arkansas the fund will reimburse an owner, after he has expended $25,000, up to the maximum amount of $1.0 million per occurrence. Arkansas Code Ann., sec. 8-7-907(a). In other states, such as Illinois, while there may be a "Petrofund" program on the books, funding is so limited that the program is ineffective, and property owners in effect pay their own cleanup costs.

28. For a discussion of one of the recent programs, in Minnesota, see "Minnesota's Superfund Shield," Planning (June 1995): 22-23.

29. See the testimony of Carol M. Browner, supra.

30. Ibid. Administrator Browner's testimony indicated that some of the focus will be on "soil screening guidance" to help identify appropriate portions of contaminated properties that do not need remediation, as well as on modifying remediation standards to fit the most likely land use that a property will be devoted to in the future.

31. See, for example, discussion of such programs in "Report of the Subcommitee on Land Use and Solid Waste," The Urban Lawyer,

v. 23, no. 4 (Fall 1991): 773-784.

32. See, generally, Evelyn Hall, "EIL Is Poised for Growth," Best's Review - Property & Casualty (April 1995): 40-43.

33. Ibid. Usually, coverage only applies to pollution that is accidental and sudden and which takes place onsite. For an additional premium, some insurers will include first-party, offsite cleanup or coverage for non-sudden and gradual pollution.

34. Ibid., 42-43.

35. The publication of Appraiser News was terminated after its December 1995 issue and its contents have been merged with Valuation Insights & Perspectives, a quarterly magazine, which debuted in February 1996.

Dump owner to guarantee home values

LeAnn Spencer.

The prospect of an expanding landfill next to your dream home would seem about as inviting as having a boorish neighbor throwing trash in your carefully tended back yard.

But what if the landfill owner promised to guarantee the value of your house? What if he also promised to cork the noxious odors that perfume the neighborhood, provide an attractive prairie landscape and recreational trails, and donate hundreds of thousands of dollars to an open-space preservation fund?

The developer of a one-of-kind residential community near Grayslake announced just such an agreement Thursday with the owners of the adjacent Countryside landfill.

If one can imagine such a thing as a model landfill, this appears to be it-and the operator says it may be at the cutting edge of a national trend in the aesthetics of garbage dumps.

Landfills once were in outlying, undeveloped farmland and consisted of little more than ugly, artifically molded hills dotted with flaring torches that burned off the gas produced by rotting garbage.

But as more and more residential development springs up in once-empty countryside, landfill owners must placate nervous homeowners by going beyond safely burying decades-old garbage, according to industry experts.

Prairie Crossing, a unique development with 317 homes being planned for 670 acres, is on the east side of the Countryside landfill. The community is the dream and brainchild of George Ranney Jr., an open-space preservationist and president of Prairie Holdings Corp., the development company building Prairie Crossing.

Countryside's owners, Dallas-based USA Waste Services Inc. will spend $4.5 million on improvements over the next two years to develop the good will of its neighbors at Prairie Crossing.

About 80 of the 200 acres at the landfill are being used for waste disposal. The company hopes to persuade county leaders in a year or two to give it permission to expand and wants the backing of nearby residents, who could block any expansion.

"This is a unique opportunity to build a model landfill next to a model community," said Donald Moorehead, president and chief executive officer of USA Waste, which owns and operates waste-disposal haulers and landfills throughout the nation.

Prairie Crossing is bounded by Casey Road, U.S. Highway 45 and Illinois Highways 137 and 120.

Under the agreement, USA Waste will guarantee that the original 317 home purchasers will be able to resell their homes for at least the prices they paid, plus an allowance for inflation. The homes will be priced from $180,000 to $350,000. This is the first property-value guarantee offered by USA Waste.

In addition, USA Waste will install recovery systems to reduce the amount of methane gas that fouls the air and immediately give $250,000 to an open-space preservation foundation set up by Ranney.

Landscaping to be completed by November includes native plantings of prairie flowers and grasses, as well as trees, to create an oak savanna, much like the woodlands that once comprised much of the Midwest.

While not endorsing any expansion of the landfill, Ranney said "we think they deserve a chance" to prove themselves.

The development will include single-family homes nestled in a wooded community with equestrian and pedestrian trails, a community farm, and an organic vegetable market.

The plans for the community were announced in the fall and received accolades from pro-development county leaders, open-space planners and environmentalists.

The agreement gives Prairie Holdings oversight and enforcement powers of the landfill agreement if USA Waste does not meet its end of the bargain.

Such "incentive packages" are becoming more common as landfill operators try to persuade communities to grant approval for expansions or new landfills, said Dan Shomon, spokesman for the Illinois Environmental Protection Agency. The IEPA regulates landfills and does not endorse or discourage such agreements, he said.

Waste Management Inc. of Oak Brook is offering equity protection to homeowners adjacent to its newest landfill, which is being planned for Morrison in Whiteside County. Other property-value guarantees are in place at Waste Management landfills in Kansas, Wisconsin and Indiana.

Residents are starting to realize that landfills are part of

the infrastructure, said Will Flower, spokesman for Waste Management, but they are nervous about living next to one.

Landfill operators, he said, are more in tune with the needs of residents and are offering guarantees to them in the form of property-value protection, as well as the development of recreational uses for closed and capped landfills.

Browning-Ferris Industries Inc. offers property-value protection to homeowners of nearby landfills in Illinois and Wisconsin, said spokesman Jim Ambroso.

In addition, the company is working on an annexation agreement with Zion that would include incentives for the community. Browning-Ferris owns a landfill near Zion that it wants to expand. If it doesn't get permission, the landfill must close this fall.

In Grayslake, the agreement between USA Waste and Prairie Holdings prohibits USA Waste from building an incinerator at Countryside, accepting hazardous waste, and accepting waste by rail.

The Liberty Prairie Foundation will help fund projects for the Liberty Prairie Reserve, a 975-acre conservation area being managed by Libertyville Township and the Lake County Forest Preserve District. cOntributitions will start in 1995 and are expected to amount to about $300,000 a year.

METRO LAKE

ZION LANDFILL THINKS BIGGER ONCE AGAIN

LeAnn Spencer, Tribune Staff Writer.

Five years ago when it was feared that a Zion landfill was about to grow, neighbors gathered more than 8,000 signatures on a petition and strong-armed county officials to designate the land for a forest preserve.

But the so-called Stateline Preserve was never to be born. A shortage of funds brought on by the property-tax cap meant that only the most ecologically significant land could be purchased and protected from development by the Lake County Forest Preserve District.

And when district officials abandoned plans for the preserve in the fall of 1992, the way was paved for Houston-based Browning-Ferris Industries Inc. to use the land for burying more garbage.

Hearings on the company's expansion plans begin Tuesday before a pollution control board appointed by Zion. The hearings are expected to last several weeks. Browning-Ferris wants to use another 105 acres for a municipal sanitary landfill; now, garbage is buried on 130 acres of the 250-acre site.

If approved by the city, and then by state and federal regulators, the expansion would add up to 20 years of life to the dump, which can take no more garbage without permission. The whole process could takes several months, or longer, to be completed.

Browning-Ferris officials have worked hard to woo support this time for their plans. They spent months last year meeting with neighbors, and promised to guarantee property values and share landfill receipts with communities.

Nonetheless, environmentalists remain wary. They fear that chemicals might leak into the area's water supply. Residents living near the landfill rely on well water.

"Ground water is an Illinois state resource," said Earl Johnson, executive director of Illinois Citizen Action, a government watchdog and environmental organization. "Any toxic materials that get into an aquifer can destroy it. We want the maximum protection built into the landfill.

"All landfills, no matter how well they are built, sooner or later will leak," said Johnson, who wants backup systems installed at the landfill.

Officials for Browning-Ferris said this week that the landfill design goes beyond state and federal requirements, which vary from site to site.

"This system is designed not to leak," said company spokesman Jim Ambroso, who added that plans call for two plastic liners, as well as a densely compacted clay layer.

"It's way beyond the required liner systems under state and federal guidelines. We have good-quality clays there to begin with, and the added layers of plastic are additional safeguards to help protect surrounding ground water."

The company's plans call for expanding the landfill on 75 acres of unused land. The rest of the expansion would include "piggybacking" garbage on another 30 acres already used, Ambroso said. Overall height would rise to about 95 feet in a gentle slope and be landscaped with trees and shrubs.

The Zion landfill, which is at Green Bay Road and 9th Street, is a linchpin in the county's solid waste disposal plans, officials say, especially in light of a new Wisconsin law that effectively keeps Illinois garbage from going to dumps across the state line.

The landfill has the support of 36 municipalities and the county, which, as members of the Solid Waste Agency of Lake County, last year contracted for up to 30 percent of the space in the expanded landfill.

The solid-waste agency has a similar agreement with Dallas-based USA Waste Services Inc., owners of Countryside Landfill near Grayslake.

The landfill also has an agreement with Zion that includes a one-time cash payment to the city of $100,000, as well as a portion of landfill receipts, which city officials have estimated could average roughly $500,000 a year.

LOCAL

LANDFILL SESSION IN BLISS PICKETED EAGLE GROUP TIES PROTEST TO OBSERVANCE OF EARTH DAY

By BILL PRICE - Wyoming Corespondent

About 20 adults and children, representing Concerned Citizens of Eagle, Wednesday evening picketed outside St. Joseph's Church Hall to show their opposition to the possibility of Browning-Ferris Industries constructing a landfill in the Town of Eagle.

Connie Larson, a member of the citizens group, said the picketing was timed to coincide with the observance of Earth Day. Mrs. Larson said the group is doing its part in protecting the environment by opposing any BFI landfill in Eagle.

The pickets chose the church hall because BFI officials were holding an information open house inside. BFI officials have repeatedly told Eagle residents that whether or not a landfill is constructed would be up to the majority of town residents.

Mrs. Larson said she believes that even if the BFI landfill is "state of the art," it would create an environmental hazard.

The issue has divided residents of the town, and this week half- and full-page ads in area shoppers have fanned the flames of disagreement between the two camps.

In one ad, paid for by BFI and signed by 80 Eagle residents, voters are being encouraged to support a straw vote scheduled for Friday on whether or not BFI should locate a landfill in the town.

The American Arbitration Association will oversee Friday's straw vote. The polls will be open from noon to 9 p.m. in Bliss Recreation Hall. All full-time town residents are eligible to vote.

Mrs. Larson said she is not sure if she will participate, calling the vote unfair to property owners who do not use the Town of Eagle as their permanent address.

The Eagle Town Board at 8 p.m. today will reconvene a public hearing on a local law that gives the Town Board power to issue permits for the construction of landfills. Now, no such law is on the books and in theory, any firm could come into the area and build one.

The hearing will be conducted in the Bliss Recreation Hall on East Main Street.

Last week the board attempted to hold a public hearing on the issue, but a technicality forced it to be postponed.

BFI has offered to pay the town $1 million to $2 million a year for each year the landfill is in operation. The amount i negotiable and would be based on the size of the facility.

The project is expected to create 25 to 50 jobs, and promises to give job training and preference to Eagle reside

The firm also promises a $500,000 to $1 million annual p to the town for a locally controlled economic trust fund. BF the fund could total $30 million over 20 years and could for economic development on other projects beneficial to t

The firm also promises a property value protection guarantee no loss of real estate value and $25 mill million in local construction spending.

BFI has also offered free trash disposal f residents.

The Town Board will vote on the local law public hearing.

CSAB STUDY: ENVIRONMENTAL INEQUITY STEMS FROM ECONOMICS, NOT RACISM

Environmental inequity has more to do with economics than racism, according to a report issued by the Center for the Study of American Business (CSAB) at Washington University. The conclusion was reached in Environmental Inequity: Economic Causes, Economic Solutions by Thomas Lambert and Christopher Boerner, who analyzed census information relating to 167 industrial facilities and waste sites in the St. Louis area.

A major finding includes the tendency of minorities to move near polluting facilities instead of polluting facilities moving near them. When an industrial facility or waste site moves to a neighborhood, higher-income people and whites usually move out. This makes property seem less desirable and therefore less valuable. The report found that the lower prices attract poorer, typically nonwhite residents. Around these facilities, concentrations of minorities usually increased at a disproportionate rate, family incomes fell and housing values rose at a slower rate, said the report.

The findings are significant for environmental justice policy because regulating where polluting and waste facilities may locate are only temporary solutions that are unlikely to end long-term environmental inequity, according to Boerner and Lambert.

They propose that industry offer various compensation options to people living near undesirable facilities so that the surrounding property is not devalued. The schemes may include direct payments to affected landowners and "host fees" or community general fund contributions; grants to improve local health-care delivery and education; and providing parks and other recreational projects.

The report cites Browning Ferris Industries (BFI) as a company that guarantees property values near its sites, compensating residents whose property values fall when a BFI plant moves in. For a copy of the report, Policy Study 125, call (314) 935-5630.

NEWS

Sampson gives nod to landfill Many protest plan; final vote Feb. 17

MARTHA QUILLIN

CLINTON -- In the high-tech trash business, regional landfills are the wave of the future -- but some Sampson County residents don't want to be on the cutting edge.

When county commissioners held a public meeting Monday night to discuss a proposed landfill where trash would be brought from up to 60 miles away, 500 people crowded into the Clinton-Sampson Agri-Civic Center to hear about it. More than 60 of them took three-minute turns at the lectern either to encourage the county to go ahead with the project, or beg them to reconsider.

Supporters say a privately run, regional landfill will solve Sampson's solid waste problems for years into the future while raising millions of dollars for the rural county's coffers. Opponents say it will make the county a dumping ground for Eastern North Carolina and threaten groundwater supplies.

After concluding the public hearing, county commissioners discussed the proposal in closed session for about an hour, then voted unanimously to give it preliminary approval. A final vote is scheduled Feb. 17.

If the landfill is approved by the county and state, it would be built on 500 acres adjacent to the existing landfill a few miles west of Clinton.

The meeting opened with county Health Director Kenneth Jones showing a promotional film about Browning-Ferris Industries, the Texas company that would build and operate the facility, and a news program that profiled a landfill in a small town outside Detroit. That facility, town officials said in the program, had generated millions of dollars that were used to upgrade town services, and had become a tourist attraction in itself.

The film showed people skiing on top of a snow-covered, trash-filled mountain, and golfing on top of a carefully landscaped garbage heap. In the BFI promotional film, race cars zoomed around the Charlotte Motor Speedway outside Concord -- the infield of which is a former trash dump.

But some residents were not convinced that the landfill -- which could receive non-hazardous waste from some 30 counties -- would be a good neighbor. They were concerned about BFI's environmental record in other states, and about possible long-term hazards of the dump.

"We don't get enough snow to ski, we work too hard to play golf and we can't afford race cars," Bernice Cooper of Roseboro told commissioners. She asked them to pursue recycling efforts and to build a landfill that would serve Sampson County alone.

Bob Wheeler, also of Roseboro, agreed. "I'm not opposed to a landfill," he said. "I'm opposed to a regional landfill. I do not want everybody else's trash in my backyard."

But Dexter Matthews, chief of the solid waste section of the state Department of Environment, Health and Natural Resources, said Tuesday that because of the high cost of building landfills under new state and federal regulations, regional facilities are being discussed by more than half a dozen clusters of counties from the coast to the mountains.

Some, he said, would be operated by commercial outfits like BFI. Others would pool county resources for construction and operation.

Before 1972, when the state initiated regulations on sanitary landfills, there were as many as 450 open dumps in towns and cities across the state where trash was poured into piles and set afire. Since then, the state has required that trash be put in central facilities and buried each day with 6 inches of dirt to reduce health hazards.

As those landfills reach capacity -- as the existing one in Sampson County is expected to do by late 1993 -- new ones must be built, conforming to the latest regulations. These "high-tech" landfills, designed to prevent groundwater contamination, must be lined with a clay or plastic barrier and equipped with collection systems to catch liquid residue.

Such landfills cost in the neighborhood of $240,000 to $300,000 an acre to build, putting them out of reach for counties like Sampson unless residents agree to considerable increases in garbage collection fees -- up to $200 a year per household, Jones said.

Over the 20-year contract being negotiated with BFI in Sampson, Jones said, the county's share of tipping fees at the landfill could be as much as $50 million, with county residents enjoying free trash collection and the closest residents getting price guarantees on their homes and property. If the county has to build and run its own high-tech landfill, Jones said, it could cost residents $50 million over 20 years.

To people like Bruce McLamb of Clinton, it is a simple choice. Speaking at the hearing in favor of the landfill, he said, "If we're going to do it, let's at least make money off it."

BOARD MAPS NEW STEP TO BLOCK LANDFILL

The Albion Town Board will take another step toward blocking an 80-acre landfill adjacent to the Erie Canal when it holds a public hearing March 11 to consider revising its zoning ordinance.

Meanwhile, Waste Management of New York took a counter measure Tuesday as it announced that it will guarantee appraised values on land which abuts the Towpath Environmental & Recycling Center east of Transit Road once the landfill begins operating.

The company will reimburse the price difference for any landowner who sells property for less than its appraised value within eight years of the start-up of the landfill, Waste Management spokes person Cindy Jessup explained.

Waste Management Inc. is leasing the 80 acres of idle land from John and Irene Smith, the bankrupt operators of a former landfill on Transit Road. The $105 million project is proposed for a site on Densmore Road, about 1,000 feet south of the Erie Canal.

Because of a new anti-landfill majority on the Albion Town Board since Jan. 1, however, the opening of the landfill has been thrown into doubt.

The March 11 hearing will be the third step taken since January by the new board to prevent "our town from becoming a dump," said Supervisor Edward R. "Ted" Scharping, a longtime Orleans County realtor who took office at the beginning of the year.

Landfill development in Albion was halted early in January when the new Town Board lineup returned Waste Management's permit application as incomplete and then declared a 120-day moratorium on any new landfill applications.

The original plan was for Waste Management Inc. to dump 500,000 tons of solid waste a year that "would come from anywhere and everywhere including Canada," Scharping said.

"A big question for us is whether enough residents of Albion (population 6,500) will stand up to threats of a lawsuit," Scharping said. "We have retained Daniel A. Spitzer of the Hodgson, Russ firm of Buffalo."

"None of the three proposals had any teeth to them," said Legislator Edward Ryan, D-Syracuse, the minority leader. "All they accomplish is giving Warner something to talk about during next year's political campaign."

Livingston Co. sales tax may save property tax

TONY PARKER

PONTIAC - Approval of a proposed sales tax increase Nov. 4 would not only help pay for centralized emergency service dispatch, but also result in a property tax savings, the Livingston County Board decided Tuesday.

The board unanimously adopted a resolution to use any surplus revenue generated by the quarter-cent sales tax increase to abate that much from the county's General Fund levy.

Based on the most current numbers available, the sales tax hike would generate $692,000 annually, with about $400,000 earmarked to pay for the dispatch service in conjunction with enhanced 911.

The remaining $292,000 would be abated from the General Fund levy. For the owner of a $60,000 home, the savings would be about $14.30 per year.

Money from the increase must be used for public safety purposes, but Finance Committee Chairman Carl Borngasser said the money will be placed in the Sheriff's Department budget that is part of the General Fund. The resulting savings would be passed on to taxpayers through an abatement in the county's General Fund levy, he said.

Other options presented by Borngasser include using $100,000 of the money for a juvenile detention agreement with Salem Children's Home in rural Flanagan or using the extra money to help the struggling General Fund.

The referendum was requested by 911 officials because of financial difficulty in the centralized dispatch program, which has a $60,000 annual deficit. The revenue would replace $305,299 in annual fees now collected from emergency service agencies, including $106,249 now paid by the county from its General Fund.

In other business

The board:

- Amended the host-county agreement with American Disposal to reflect landfill operation changes the company agreed to implement in response to neighbors' concerns about blowing debris and other issues.

The changes require the company to: monitor wells within 1,500 feet of Livingston Landfill on a quarterly basis and randomly sample one home's well every three months within a one-mile radius of the facility; extend property-value guarantees from a quarter-mile to one-mile radius; and curtail landfill operations when sustained wind speeds reach 30 mph, down 5 mph from the original contract.

- Authorized Livingston Manor Administrator Sue Anne Myers and Livingston County engineer David Winters to enter binding contracts of up to $10,000 with consent only from County Board committees.

Previously approval was needed by the entire 28-member board, but officials said that often meant waiting several weeks for a necessary supply or piece of equipment.

- Learned deputy coroners Sue Mennenga, Rita Mills, David Murphy, Richard Ores, Julie Runyon and Danny Watson have completed the state's 40-hour basic coroner training course.

- Reappointed Elmer Ifft to a three-year term on the Belle Prairie Drainage District board of trustees; Steven Haag to a three-year term on the Northeast Sullivan Mona Drainage District board of trustees; and Merle Jehle to a one-year term on the Northeast Sullivan Mona Drainage District board of trustees.

METRO LAKE

GRAYSLAKE PROJECT SELLS ENVIRONMENT-FRIENDLY LIFESTYLE NATURE RIGHT AT HOME IN SUBDIVISION

LeAnn Spencer, Tribune Staff Writer.

In the nearly five years since the seeds for the Prairie Crossing subdivision were planted in the rolling landscape of north-central Lake County, more than 75 homesteads have taken root in this Rockwellian portrait of Midwestern utopia.

There's a village green with gazebo, a community-sponsored organic garden and food co-op, pathways lined with hedgerows and fruit trees, a petting farm, a children's garden, horse stables and even a restored historical barn and farmhouse.

The goal, designers of the Grayslake project say, was to foster a sense of community akin to the days of yesteryear, with 19th Century-style homes clustered on smaller lots and surrounded by generous helpings of open space.

"We were drawn by what they were doing, and ecologically, they are doing wonderful things," said Mark Loughmiller, 38, who with his wife, Kelly, was one of the first to make a deposit on a house at Prairie Crossing.

"When I looked at other developments in Lake County . . . I bought into the idea that (Prairie Crossing) was certainly a worthy experiment to become involved with," said Loughmiller, the county's recycling coordinator.

Across the Chicago area, other subdivisions promise neighborliness and even conservation, but few have been able to create the kind of lifestyle package found at Prairie Crossing.

With its bucolic pastures, verdant wetlands and inviting ponds, Prairie Crossing has won acclaim as a "conservation community" by national environmental groups such as the respected Nature Conservancy and the Conservation Fund.

It is a design concept few had heard about when the project was announced in 1992, but today, the idea is considered by some builders and land planners as an antidote to sterile and unappealing suburban sprawl that isolates people from each other.

This is important, experts say, because development is spreading deeper into the collar counties, far from traditional town centers. Many people who live in subdivisions feel out of touch.

"The community concept is a big draw. People are far from town, and they want to feel a sense of community and like they are at home," said Roy Krughoff, an Aurora home builder and president of the Northern Illinois Home Builders Association.

Another factor, Krughoff noted, is that one subdivision often looks like the next, and people want something unique.

"If you blindfolded someone and put them in the middle of many subdivisions and took off the blindfold, they could name 50 different locations that they might be at--and they would be correct," he said.

Other places that promote a strong sense of community, Krughoff said, include Stonebridge in Aurora and Mill Creek in Geneva. Both include appealing neighborhood centers with recreation areas and some small commercial stores.

Another development often cited for its emphasis on native landscaping is the Reserve at the Merit Club in Libertyville.

In the case of Prairie Crossing, those who buy homes also purchase a back-to-nature lifestyle that includes potluck suppers and Sunday afternoon concerts. The deal includes a long list of covenants governing house color and design as well as guidelines for ecologically safe landscaping.

The subdivision even has its own environmental manager who coordinates the care of the 463 acres of open space and advises homeowners on natural landscaping.

"We (biologists) know how to restore native landscapes on 1 acre and up," said Michael Sands, environmental team leader.

The challenge was making that work on lots smaller than a half-acre in a subdivision that is surrounded largely by native landscapes.

"Homeowners told us that they wanted to do things differently," said Sands, whose recommendations included less lawn turf and more drought-tolerant prairie plants.

"One of our goals," Sands said, "is to turn the average home buyer into an environmental advocate."

That can be done, he said, by teaching neighborhood conservation. As a result, many yards include tall native grasses and wildflowers that meld into untamed open spaces. Some owners even have creatively incorporated vegetable gardens as the

centerpiece of their "landscaping."

For homeowner and ecological consultant Karin Wisiol, life at Prairie Crossing resulted in a new venture after she and other homeowners started looking for help in designing natural-looking yards.

She has founded the northeastern Illinois chapter of the Wild Ones-Natural Landscapes, a national organization that promotes the use of prairie plants in home landscaping.

"An ordinary development wouldn't have drawn me, and we liked the idea of living in a community philosophically created to be ecological sound," said Wisiol, who with her husband, Klaus, a retired Commonwealth Edison executive, is planting a prairie garden in her yard.

Prairie Crossing was the dream of the late Gaylord Donnelley, a Lake County philanthropist and businessman, and his wife, Dorothy. They bought several hundred acres in the area after a controversial high-density residential development for the property was rejected by county officials in 1972.

Instead of the proposed 2,200 homes, Prairie Crossing will have 317 houses on 700 acres. More than half of the property has been left in common open space owned by the homeowners association, including a network of trails that will connect to nearby forest preserves and the adjacent 2,500-acre Liberty Prairie Conservancy.

Prairie Crossing was created by Donnelley's nephew George Ranney Jr., a Lake County businessman, and his wife, Victoria Post Ranney. They are the president and vice president, respectively, of Prairie Holdings Corp.

Their idea was to carry out Donnelley's vision of a community in harmony with the environment, economically sound but environmentally sensitive as well.

In the nearly two years since the first model house opened, about 75 dwellings have been built and sold, mostly to white-collar professionals. That's about an average sales rate for new suburban development, according to industry observers. Base prices range from $195,000 to $410,000.

Frank Martin, project manager for the Chicago-based Shaw Co., which is building the houses that were designed by well-known Chicago architects, likes Prairie Crossing so much that he moved his family there from Chicago.

"We're not just building a subdivision. We're truly building a community here, and that is what is exciting," said Martin, who commutes to his Chicago office via the recently opened Metra North Central rail line.

Even an adjacent landfill hasn't seemed to bother many people, said the developers. That may be due in large part to an agreement Ranney made with the owners of Countryside Landfill.

Under terms of that contract, the landfill operators guarantee property values in the subdivision. The landfill also promised to put in several million dollars of landscaping improvements and odor controls beyond what is required by state and federal agencies.

Neighbors West

LANDFILL NEIGHBORS GET SOME CONSIDERATION THE LAWMAKERS AIM TO GUARANTEE THE VALUE OF SOME PROPERTIES IN VAN BUREN.

PATRICK LAKAMP The Post-Standard

He couldn't stop Onondaga County legislators from deciding to open an ash landfill in his district, but Legislator Robert Warner presses on so Van Buren residents can live with the decision.

Warner - who brought three proposals to the county legislature's September session last week - scored a split decision.

Lawmakers passed one of his measures and rejected a second, and he pulled a third proposal shortly before it was to be considered.

Lawmakers approved, by a 23-1 vote, a proposal asking the Onondaga County Resource Recovery Agency to "make every effort" to establish a property stabilization plan.

Such a program would guarantee the market value of properties near the landfill off Brickyard Road.

If homeowners can't sell their houses at a decided-upon value, the homeowners would be paid the difference.

Residents who live near the next county dump deserve a plan to help make up for the noise, the smell and the impact on property values, Warner said.

Lawmakers defeated a second proposal, 7-17, to ask the trash agency to "protect the interests of the town of Van Buren" if the site is sold to a private company.

At the last minute, Warner pulled a proposal asking the trash agency to compensate the town for lost property taxes.

Last month, the county authorized the agency to spend $1.2 million to buy a remaining 364 acres from property owners for the landfill. The site, about one square mile, eventually will be used to bury ash from the county's trash incinerator.

Warner's proposals would not have required OCRRA to do anything, but would simply ask the agency to consider the ideas.

METRO

Council expects to appoint new chief on Aug. 19 Town panel has interviewed four candidates but wants more time before making its selection.

LINDA KARN; CORRESPONDENT

DANVILLE, Ind. - The Danville Town Council announced Monday night that it expects to name a new police chief Aug. 19.

The council interviewed four candidates during an executive session prior to the regular meeting, but decided more time was needed before making the selection.

William Cope, who submitted his resignation July 1, will continue to oversee the department until a new chief is hired.

In other business, Larry Wright, executive director of Twin Bridges Recycling and Disposal Facility, told council members that about 60 letters have been submitted to homeowners who qualify for Waste Management's property value guaranteed program. The program is a means to protect property values of homeowners surrounding the landfill.

As part of the negotiations for the landfill's February 1994 annexation into the town, the council asked Waste Management to guarantee property values to homes surrounding the landfill along Cartersburg Road to County Road 150 East and County Road 200 South.

Wright said Waste Management expanded the guarantee area to include homes not only surrounding the landfill, but also near the proposed Hendricks County Reliever Airport along County Road 200 East.

Wright said there is no mandatory obligation to sell homes to Waste Management, but added that the offer is good as long as Waste Management operates the landfill. Wright said he believes the firm will be operating the site for another 30 years.

Wright said about 30 owners have returned verbal or written responses. He said Waste Management has hired Certified Appraiser Howard Thomas to conduct appraisals. He said homeowners can hire their own appraisers at Waste Management's expense.

He emphasized that Waste Management actually does not have a firm plan of what to do with the properties once they are acquired. Wright speculates that Waste Management will rent the properties.

The program includes an option for the owners to lease the property until they can decide where they want to reloc Wright said the company has no desire to demolish any of the ho

He said he hopes all the properties could be utilized and to the council the area will not be designated as a Habitat f Humanity subdivision. He said those homes do not fit into Habitat'. criteria.

However, he did warn that the guarantee is not transferable to future homeowners because they know the landfill exists.

When the Town of Danville agreed to Waste Management's annexation and rezoning request, the property was rezoned to "plan development district extraordinary" so the landfill's disposal area could be expanded from 119 acres to utilize an additional 135 acres.

Because of the annexation, Waste Management received town utilities with the intention to release the leachate, or rainwater runoff, into the sewer system and the town's waste water treatment plant.

The town has not begun accepting leachate into the treatment plant.

Landfill gets state approval Sugar Creek site eases space crunch; opponents fear it will ruin acqifer.

MIKE RICE; BRIAN BURNES
Staff Writers

The Missouri Department of Natural Resources has approved a 208-acre landfill in Sugar Creek despite more than three years of protests from residents who don't want it near the area's main water source.

The state agency on Monday approved a solid waste management permit for the Courtney Ridge Recycling and Disposal Facility on the Missouri River bluffs near Missouri 291 and Courtney Road.

The permit will allow Waste Management Inc. to open the landfill next year after its nearby Rumble Landfill reaches capacity. Construction should start this summer, said Kevin O'Brien, the company's division president who will oversee the new facility.

Proponents said the new landfill could help solve the metropolitan area's dwindling landfill capacity. It is expectedto

house trash for 20 years from much of Kansas City, eastern Jackson County and Clay County.

But opponents are concerned about polluting an aquifer south of the Missouri River.

The nearby Courtney Bend aquifer and well fields are the main water source for Independence, which also sells water wholesale to other utilities in Jackson and Lafayette counties. Nearly 250,000 customers tap that water source.

''The DNR has betrayed us by permitting the landfill," said a leading opponent, Mary Ann Wilson of Independence. ''It is endangering our water supply."

Lee Moore, a retired real estate broker, said the fresh water from the Courtney Bend aquifer has drawn thousands of residents to eastern Jackson County.

''I'm so furious, I could bite a nail," said Moore of Independence. ''Can you imagine trying to clean a head of lettuce with bottled water?"

But Courtney Ridge officials and Sugar Creek leaders contend that the facility will be safe. The permit contains more than 30 stipulations, such as a special synthetic liner to help prevent leaks, a ''catch" system for methane gas and restrictions on hazardous wastes.

Department of Natural Resources officials noted that they inspect sanitary landfills four times a year to ensure they are in accordance with state guidelines.

''We've always felt that this will be one of the most regulated landfills in the state," said Bob Buckley, Sugar Creek assistant city attorney.

But Independence Water Department Director Randy Vest said he remained concerned about blasting in the mostly industrial area and monitoring the landfill after it closes. ''The risk is still there," he said.

Opponents have written letters to the state, hired engineers to prove the facility will leak and introduced legislation.

But in May 1993, the Sugar Creek Board of Aldermen approved the special-use permit after the stipulations were added. The city held five previous public hearings.

Opponents continued communicating with the state and were optimistic earlier this year when the Department of Natural Resources extended its review of Waste Management's application.

That delay gave two area legislators, Sen. Ronnie DePasco and Rep. Dennis Bonner, more time to push legislation that would have banned construction of all landfills near water sources.

But DePasco said Tuesday that rural legislators, dependent on revenue generated by landfills, helped kill both proposals. Although DePasco revised his bill several times, ''(rural legislators) said I would be killing all landfills because they all sit atop aquifers."

Approval of the landfill is a boon for Sugar Creek, which lost a significant corporate neighbor in 1982 when the Amoco Oil Co. refinery closed.

Buckley said the city would receive 10 percent of Waste Management's gross receipts from the Courtney Ridge facility each year for the life of the facility. A report two years ago estimated that the new landfill could generate $43 million for the city through the year 2015.

Sugar Creek Mayor Charles Dumsky, who championed efforts to have the landfill permit approved, was unavailable for comment

Tuesday.

To placate some Sugar Creek residents, Waste Management has offered a program guaranteeing the replacement value of their homes. If homeowners within a designated district cannot sell their properties for an agreed-upon appraised value, Waste Management will make up the difference.

About two dozen other property owners have taken advantage of the program, O'Brien said.

The Courtney Ridge approval is the second big victory for area landfill proponents this spring. Last month, the Kansas City Board of Zoning Adjustment approved a 39-month extension of the Southeast Sanitary Landfill at 8301 Indiana Ave. That facility had been scheduled to close by Jan. 1, 1996.

Defeating both landfill proposals would have left the Johnson County Landfill and the Forest View Recycling and Disposal Facility in Kansas City, Kan., as the area's two main trash disposal sites.

Nick Artz, a principal for Franklin Associates, a Prairie Village solid-waste management firm, has said the Courtney Ridge facility and the Southeast Sanitary Landfill extension would improve the area's landfill capacity, especially on the Missouri side.

But Courtney Ridge opponents said the Sugar Creek facility could be unnecessary if a solid waste transfer station is built in Independence. The City Council will decide next month whether to issue the special-use permit, which also needs state approval.

Up to 240 tons of trash a day would be shipped from the station to the Show Me Regional Landfill in Warrensburg. Because the station would be an indoor facility, trash haulers would sustain less wear and tear on their trucks, said Jim Sharpless, a consultant for the station's operator, Allied Waste Industries.

''We don't think this will affect us," Sharpless said. ''It's still to the trash haulers' advantage to come to us."

Rusk County landfill slated for late 1994

By Tim J Sheehan

Eau Claire, WI, US --

If all goes according to plan, a new state-of-the-art landfill could open in Rusk County in late 1994.

But it won't be owned by the local company formed nearly two years ago to design and build the facility.

Waste Management of Wisconsin, the state's largest solid waste handling firm, has bought Rusk County Landfill Inc. and the site in the town of Stubbs outside Weyerhaeuser, which recently won approval from the state Department of Natural Resources. Waste Management of Wisconsin is a division of one of the country's largest waste- handling firms, Waste Management of North America.

In 1991 William Rands and a northern Wisconsin developer, Jack Ardoyno, formed Rusk County Landfill Inc. to build and operate the proposed landfill. Rands, president of Rands Trucking and Disposal in Ladysmith, said in a release on the sale that he is confident in Waste Management's environmental record.

"I believe Waste Management's environmental expertise is greater than any other company's in Wisconsin," Rands said.

DNR officials who administer the long, complicated landfill sitting process confirmed Rand's assessment of Waste Management's history in the state.

"We see the facilities they run in the state as being run well," Paul Huebner, site evaluation unit leader, said.

Waste Management also operates waste transfer stations, recycling programs and a trucking division.

The Rusk County project, if given the final go-ahead by the DNR, would be the company's seventh state landfill and the first in the northern part of the state.

Lynn Morgan, manager of government affairs for the Menomonee Falls-based company, said the firm is looking for expansion sites in areas of the state it does not serve.

"We are always looking to expand our areas of service," Morgan said. "The opportunity came up in Rusk County for us to offer our services up there."

Morgan said the site, about a mile north of U.S. 8 east of Weyerhaeuser, is a good site with good planning for the establishment of the landfill. In late July the project cleared a major hurdle after the DNR issued a favorable ruling on the project.

Called a feasibility determination, the ruling found there was sufficient need in the area proposed to be served to justify the project. The determination also found the facility as proposed was environmentally feasible, provided the developers followed specified guidelines.

Hydrogeologist Timothy Kessenich of the DNR's Bureau of Solid and Hazardous Waste Management said three hurdles remain.

The developers now must file a plan of operation with the DNR. Once the DNR receives the detailed plan spelling out the technical aspects of the landfill and how it will be run, the department has 90 days to seek refinements of the plan or reject it.

When the first phase of construction is completed, the site is reviewed again before a license application is considered, Kessenich said. Morgan said the site's new owners will file a plan of operation with the DNR this fall.

"If we are successful, we could begin construction in the spring and be on line in late 1994," Morgan said.

Kessenich agreed that with that timeline, assuming all the steps in the licensing procedure stay on track.

One additional hurdle Waste Management will have to clear that wasn't a problem with the former local developers of the Rusk County landfill is a state statute requiring companies seeking a landfill license to comply with all regulations at all other sites the firm operates or owns.

Morgan said Waste Management does not expect the statutory hurdle to be large.

"We don't anticipate any problems with that," Morgan said.

When Rands, who was president of Rusk County Landfill, unveiled plans for the landfill, some area residents objected to the proposal.

The town of Stubbs had filed for a contested-case hearing with the DNR on the project before reaching an agreement with the local developers.

Morgan said Waste Management will honor the signed agreement with the town of Stubbs. Under that agreement Waste Management agrees to pay the town about $300,000 over the 14-year anticipated life of the landfill; blacktop the town road leading to the site; provide the town with free waste disposal; and guarantee property values of neighboring landowners.

Local/State

LANDFILL FIRMS VOW TO PROTECT PROPERTY VALUES 1 MILE FROM DUMP

Rob Tucker / The News Tribune

Local garbage companies have increased their commitment to buy out disgruntled property owners near a proposed East Pierce County dump.

The companies, joined together as Land Recovery Inc., will expand their "property value protection zone" to a 1-mile area surrounding the 320-acre landfill site, according to spokesman Dan Syrdal.

Property value protection means that LRI will buy land or subsidize the selling price if an owner within the zone is unable to sell at fair market value after attempting to do so for six months, he said.

The old zone boundary was one-half mile. The expansion area includes several hundred property owners south of Graham near the site at 304th Street East and Meridian Avenue East.

LRI made the decision after reviewing the testimony of Fred Lee, a California expert hired by people living close to the proposed landfill site 5 miles south of Graham. Those people oppose the landfill.

The company also reviewed community testimony during hearings at Graham last month, where several people expressed fears about declining property values near the landfill site, he said.

"Lee said 1 mile should be sufficient" to lessen adverse landfill consequences, Syrdal said.

In addition, LRI will expand the property value protection program to any land where drinking water is made unhealthful by the proposed landfill, he said.

Some landfill opponents didn't think much of the new development.

"Do I have a lot of faith in this? No," said State Sen. Marilyn Rasmussen, (D-Eatonville).

The proposed landfill is in her district.

"I don't think they can afford it," added Wendy Hall, the paid staffer for Rural Citizens Against Urban Sprawl, which opposes the landfill.

"We're not a typical rural neighborhood," she said. The area includes a Weyerhaeuser family and many others with higher-value houses and land. And it contains many horse ranchers, some of whom breed Arabians, she said.

A landfill failure would bankrupt LRI, she predicted. "This is not a Fortune 500 company," she said.

The $60 million landfill would be built over a drinking water aquifer used by thousands of south Pierce County residents.

The South Muck Creek flows nearby and floods substantially at times, blocking Meridian Avenue East, Hall showed with a video at the landfill hearings.

Testimony by others revealed that an earthquake in 1949 dried up deep wells and a lake near the landfill site. The quake also disrupted the soils on the landfill site, she said.

LRI believes that it won't be spending much money.

There won't be any adverse impact on property values or drinking water wells near the planned dump, Syrdal said.

But LRI knows that the landfill proposal and its safeguards aren't credible with nearby property owners, he said.

"We are dealing with a perception problem," he said. "But if they are right, they are protected. Otherwise, there's no cost to us."

The LRI move came after the county ended land-use permit hearings for the landfill earlier this week.

The hearings lasted 16 days and included community and expert testimony on the adequacy of the landfill's environmental impact study and whether a land-use permit should be granted.

The final decision on the permit won't come until Jan. 1, hearing examiner Steve Causseaux said.

People who have an opinion on the proposed landfill near Graham can still give it - in writing.

County hearing examiner Steve Causseaux will allow written testimony on the issues through Oct. 24.

People who want to write should send their letters to: Pierce County Hearing Examiner, P.O. Box 5767, Tacoma, WA 98405.

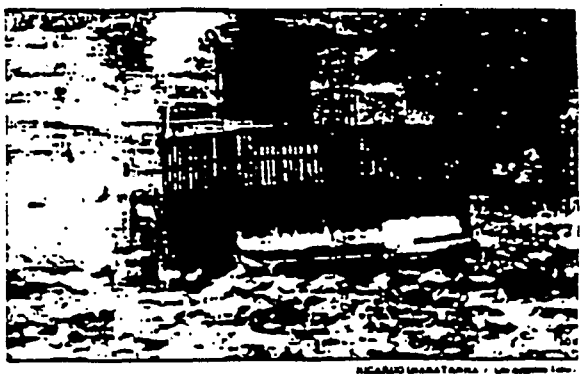
For such companies as Waste Management Inc., the nation's largest solid waste company, and the owners of the Bradley [illegible], the [illegible] is a [illegible] of money. But the [illegible] is growing more [illegible] years ago, when the landfill industry reeked of the [illegible]

Increasingly scarce dump space in Los Angeles would seem to lead to riches for those in the business. But the weak economy, increased regulation and recycling and the onset of landfill alternatives—such as hauling garbage out to the hinterlands—are working to turn once-fat profit margins for the capital-intensive business. While no one [illegible] state and industry officials were trumpeting the onset of a dump crisis in Los Angeles, the county may actually face a landfill surplus in the not-too-distant future, driving down the tipping fees that landfills charge to take a ton of garbage.



That's bad news for owners and operators of private dumps, which take in more than half of the county's 40,000 tons of trash a day. They range in size from the family-run Palmdale Disposal Co. to multinational corporations such as Waste Management, which, along with running 100 [illegible] in the United States and Canada, has interests in every aspect of business, including trash-hauling, recycling, hazardous waste and trash-to-energy plants.

"It doesn't work as well as it used to," said Tad Watson, a spokesman for Laidlaw Waste Management, Inc., which operates the Chiquita Canyon Landfill in the Santa Clarita Valley. Profits from landfills have [illegible] since [illegible] summer, environmental regulations add to landfill [illegible] cost.

Greg Loughnane, president of Bradley Landfill and Recycling Center in Sun Valley. The dump takes in 7,000 tons of trash daily.

Trash is crushed and compacted by heavy equipment at the Palmdale Disposal Co.

Paul Arelin, who 35 years ago founded Palmdale Disposal with his two brothers and an REO Speedwagon county truck, said it's hard to raise your prices as fast as they make up the new [illegible]

In Los Angeles County, the average tipping fee is $21 [illegible] a state survey showed. But among private facilities the fee is higher, with Bradley charging $33.5[illegible] a ton, while dumps in outlying areas such as Palmdale Disposal and Chiquita Canyon charge $30 and between $25 and $30 a ton, respectively.

But at the same time, both public and private dumps now must pay for high-tech liners, extensive recovery systems for the toxic methane gas given off by rotting garbage and trust funds to cover the costs of closing a landfill once its full. Federal laws also make dump owners pay for any cleanup that may be required for 30 years after the landfill closes.

"Twenty years ago, you or I could just dig a hole in the ground and put garbage in," Watson said. "But now it's become a real scientific industry."

Waste Management, for example, has spent $35 million over the last five years on new liners and gas recovery systems at the Bradley site. It purchased the site for $6 million in 1986.

For his relatively small operation, taking in 700 tons a day from the Antelope Valley, Arelin said he has set aside $2 million in a trust fund for post-closure cleanup costs.

Analysts see another long-term shift in the industry that will cut into profits: required volume because of recycling and reuse of materials. "We think landfill volumes are going to be under pressure for a number of years," said Mark Bain, an analyst at New York-based Boston Securities Corp.

Recycling Burying Profits of Dump Operators
Trash: Fears of a landfill shortage for L.A. County vanish as recycling and plans for new facilities combine to drive down per-ton load fees.
Los Angeles Times (LT - TUESDAY July 20, 1993
By: JONATHAN GAW; TIMES STAFF WRITER
Edition: Valley Edition Section: Business Page: 15
Word Count: 1,324

On the northeast edge of the San Fernando Valley lies a hole in the ground that makes the Rose Bowl look downright Lilliputian.

Filling the 22 million cubic yards of air space, equal to about 20 of the Pasadena arenas, give or take a couple, will keep Greg Loughnane and his staff busy for the next 10 years.

Driving his sky-blue Ford Explorer along the rim of the Bradley Landfill and Recycling Center, he looks 70 feet down where garbage trucks and bulldozers maneuver a multi-ton mound of Los Angeles trash like so many ants scurrying around a beetle carcass.

"The smell isn't that bad from up here," said Loughnane, who is president of the landfill and recycling center that takes in 7,000 tons of garbage a day.

For such companies as Waste Management Inc., the nation's largest solid waste company and the owner of the Bradley facility, the smell is still that of money, but the scent is growing more faint than in years past when the landfill industry reeked of the stuff.

Increasingly scarce dump space in Los Angeles would seem to lead to riches for those in the business, but the weak economy, increased regulation and recycling, and the onset of landfill alternatives--such as hauling garbage out to the hinterlands--are working to trim once-fat profit margins for the capital-intensive business. While not long ago state and industry officials were trumpeting the onset of a "dump crisis" in Los Angeles, the county may actually face a landfill surplus in the not-too-distant future, driving down the tipping fees that landfills charge to take a ton of garbage.

That's bad news for owners and operators of private dumps, which take in more than half of the county's 40,000 tons of trash a day. They range in size from the family-run Palmdale Disposal Co. to multinational corporations such as Waste Management, which, along with running 133 landfills in the United States and Canada, has interests in every aspect of disposal, including trash hauling, recycling, hazardous waste and trash-to-energy plants.

"It doesn't work as well as it used to," said Tag Watson, a spokesman for Laidlaw Waste Management, Inc., which operates the Chiquita Canyon Landfill in the Santa Clarita Valley. Profits from landfills have "diminished quite significantly" in the last five years, Watson said, because stringent environmental regulations add to landfill costs.

Phil Arklin, who 23 years ago founded Palmdale Disposal with his two brothers and an REO Speedwagon utility truck, said "it's hard to raise your prices as fast as they make up the new laws."

In Los Angeles County, the average tipping fee is $21.42 a ton, a state survey showed. But among private facilities, the fee is higher, with Bradley charging $33.80 a ton, while dumps in outlying areas, such as Palmdale Disposal and Chiquita Canyon, charge $30 and between $25 and $20 a ton, respectively.

But at the same time, both public and private dumps now must pay for high-tech liners, extensive recovery systems for the toxic methane gas given off by rotting garbage and trust funds to cover the cost of closing a landfill once its full. Federal laws also make dump owners pay for any cleanup that may be required for 30 years after the landfill closes.

"Twenty years ago, you or I could just dig a hole in the ground and put garbage in it," Watson said. "But now it's become a real scientific industry."

Waste Management, for example, has spent $35 million over the last five years on new liners and gas recovery systems at the Bradley site. It purchased the site for $60 million in 1986.

For his relatively small operation, taking in 700 tons a day from the Antelope Valley, Arklin said he has set aside $2 million in a trust fund for post-closure cleanup costs.

Analysts see another long-term shift in the industry that will cut into profits: reduced volume because of recycling and reuse of materials. "We think landfill volumes are going to be under pressure for a number of years," said Mari Bari, an analyst at New York-based Mabon Securities Corp.

Forty-three states, including California, have laws requiring cities to reduce the amount of trash going to landfills, Bari said. Many communities, such as Santa Clarita, use incentives to encourage residents and businesses to recycle and reduce waste, reducing landfill volumes by 25% to 30%.

In California, environmental regulations and heightened public distrust of landfills make trying to get permits to build a dump expensive, time consuming and uncertain.

Earlier this month, Waste Management abandoned plans to build a 6,500-acre dump at the mouth of the Ojai Valley in Ventura County after spending eight years and $13 million trying to win a permit. Torrance-based BKK Corp. has had plans to construct a landfill in Elsmere Canyon, near Santa Clarita, for nearly seven years, and still has not gotten so far as having an environmental impact report.

"This has always been a capital intensive business, and the impact of regulation has been to make it even more so," said Douglas Augenthaler, an analyst at New York investment firm Oppenheimer & Co. "There's no guarantee you can get the permits, and very few people can take that kind of risk."

Make no mistake, landfills can still turn trash into gold. "It's a license to steal, isn't it?" quipped one analyst.

Most companies don't break out financial results from their landfill operations. But Houston-based Browning-Ferris Inc., which owns the Sunshine Canyon landfill in Sylmar, received 23% of its $3.3 billion in total revenue in its fiscal year that ended Sept. 30 from the disposal and transfer of municipal waste. Waste Management, in Oak Brook, Ill., received half of its $8.6 billion in revenues last year from its solid waste operations.

Despite the difficulty in getting permits, some analysts and industry officials said, soon there may be a glut of dump space in Los Angeles County, particularly in the San Fernando Valley area.

The Sunshine Canyon landfill in Sylmar, owned by the country's second-largest

solid waste company Browning-Ferris, has a permit to reopen, but its expansion is tied up in litigation. Just to the north near Santa Clarita, an environmental impact report is due in the fall for BKK's proposed 190 million-ton landfill in Elsmere Canyon. Meanwhile, Laidlaw's Chiquita Canyon Landfill near Castaic has capacity left for up to 60 more years.

"I find it hard to argue that Chiquita plus Elsmere plus Sunshine wouldn't be too much for one area," said Alan Purves, market and strategic development manager for Laidlaw.

Throw into the mix three separate rail-haul proposals being developed to carry trash to remote sites in inland California and other states, where pits that dwarf any Los Angeles landfill are ready to take in the county's daily load of trash. "Everyone is trying to build these rail-haul projects, and if every one of these got built, they won't have enough garbage to make it worth their while," analyst Augenthaler said.

But Waste Management, whose Bradley Landfill will be full early in the next decade, said it plans to take trash by train out to lonely Amboy, in San Bernardino County. The dump crunch may not come now or 10 years from now, said Waste Management officials, but it will come.

"No one can predict where the garbage is going to go," Loughnane said, standing at the Bradley dump, which Waste Management plans to turn into a transfer site under its rail-haul proposal. "There are only so many potential landfills and only so many possibilities, and probably not all of them are going to get permitted or expanded, and I expect some of it will be taken out by rail."

Rail haul, most agree, will cost more than current landfills and may temporarily give owners of the last surviving landfills the chance to charge a premium. But it won't last long, observers say, and rail haul and recycling will keep a rein on price increases.

San Diego County to Unload Trash Unit

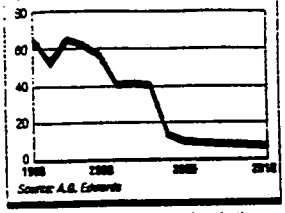
Move Reflects Sharp Rivalry From Orange County

By Jeff Bailey
Staff Reporter of The Wall Street Journal

SANTA ANA, Calif. – Orange County's trash-disposal agency is learning to run itself like a private-sector business, pushing operating costs down and competing aggressively for new customers. The efforts of the county's Integrated Waste Management Department are producing millions of dollars a year in additional revenue to help pay off huge debts left over from the county's 1994 bankruptcy.

The results aren't so gratifying, however, just to the south in San Diego County. Its government is literally being pushed out of the waste business by the bargain-basement pricing Orange County is using to dominate the Southern California trash-disposal market.

So, in an unprecedented move for a major U.S. municipality, San Diego County last month put its big garbage dumps and other disposal assets up for sale, hoping to cut its losses. And it acknowledged that it can't compete with its neighbor to the north. Orange County "convinced me that this is an open market," says Lawrence B. Prior III, San Diego County's chief administrative officer. "I don't want to be in it."



Hurt by a Dump-Capacity Glut

The proposed sale is one of the largest municipal privatization efforts to occur in the U.S., and is being closely watched. The waste-disposal business – hit by dump-capacity gluts in many regions – has grown more competitive. And many municipalities have seen their investments in dumps and trash incinerators threatened. Those investments were made largely on the faulty assumptions that disposal capacity would be scarce, and dumping fees high. To some, privatization is looking more attractive.

San Diego County hopes to raise more than $100 million from the sale, being managed by J.P. Morgan & Co., New York. Some of the nation's largest waste-handling companies are expected to bid on the dumps. Waste Management Inc. and Browning-Ferris Industries Inc. both confirmed that they submitted bids.

Plenty of Room

Projected excess dump capacity serving Southern California, in thousands of tons per day

Source: A.G. Edwards

But Orange County, which is importing thousands of tons of trash a day to its vast dumps, some from San Diego County, has thoroughly depressed disposal prices in the already glutted Southern California market. The value of San Diego County's dumps is therefore probably far reduced from a few years ago.

Trash as a Commodity

The unexpected disposal glut makes trash, of all things, a sought-after commodity. "Orange County is after our trash," a headline in the San Diego Union-Tribune warned earlier this year.

Usually a backwater of local government, financial crises in Orange and San Diego counties pushed sanitation front-and-center. After its bankruptcy filing, brought on by bond-trading losses, Orange County found it had little besides its huge canyon dumps to generate extra revenue. It mulled selling the dumps, and talked optimistically of getting $300 million or more, but decided to keep them.

Like many governments unaccustomed to competition, Orange County initially assumed that increasing revenue was as easy as raising prices: it boosted its dump fee from $23 a ton to $35 in May 1995. The government got a quick lesson in the impact that price has on demand for a service, as 19% of the county's trash fled to cheaper dumps elsewhere.

Clearly, $35 a ton wasn't going to attract trash from outside the county, which was needed to help pay creditors. Dumps serving Southern California have combined excess capacity of about 67,000 tons a day, or enough extra permitted space to handle all of New York City's trash more than twice over. And some dumps charge less than $20 a ton.

Price War at the Dumps

Orange County, learning the private-sector game, reversed course and dramatically lowered prices to $18 a ton to attract trash from other counties. And it offered all its own cities long-term disposal at $22 a ton. With those two moves, the county quickly dominated the Southern California market. That allows the waste department to pass $15 million a year to the county to retire debt.

Those prices also trashed the market. Riverside County, charging $38.50 a ton at its dumps, was forced to slash prices to as low as $23 to hang onto tonnage. Dumps in Arizona that had been attracting Southern California waste saw much of that business disappear.

More broadly, of course, a price war among dumps benefits many. Haulers, municipalities and consumers who pay to dump enjoy lower prices. But dump owners suffer. Among them, San Diego County was most vulnerable, already suffering from a disasterous trash decision.

San Diego County built and opened in 1994 a $134 million trash-sorting plant. But taking in trash already heavily sorted by recycling-happy residents, the plant essentially had little or no purpose, though it cost $27 million a year. To pay for it, the county raised fees at all of its dumps to $55 a ton. Predictably, haulers and some entire cities bolted the county system, taking their trash elsewhere, and revenue fell.

Paying Off Trash Bonds

Trash brought to San Diego County dumps, also reduced by recycling and recession, plunged to 1.0 million tons in fiscal 1996 from 1.7 million tons in 1992. At $38 a ton, today's price, that's $26.8 million less in revenue.

To stem the losses, the county closed the trash-sorting plant in 1995, and last year paid off the bonds that were sold to finance the plant. To do that, the county dipped into the general fund, borrowed cash reserves held for a variety of operations, and took out what amounts to a second mortgage on a portfolio of county property. No stone went unturned. "We were down to lint," says assistant controller William J. Kelly, who scraped together the financing.

Bill Horn, chairman of the county's Board of Supervisors, says, "We have done our damnedest to keep the County of San Diego out of bankruptcy."

The trash-sorting plant debacle and the botched pricing moves that followed hardly inspire confidence in the county's ability to manage waste operations in a competitive environment. By selling the dumps, said investment bankers at J.P. Morgan, the county could "return to [its] core competency."

Meanwhile, the city of San Diego has watched all this with increasing interest. It issues a key permit for the county's most valuable dump, Sycamore Landfill, which sits inside the city.

The city has told potential bidders for the county dumps that it wants ownership of Sycamore to pass free-of-charge to the city in about 20 years, when its dump will be full, and that it doesn't want Sycamore's capacity used too rapidly.

The conditions, of course, make Sycamore less attractive to bidders. The city, says Alan Dash, a J.P. Morgan vice president working for the county, is "working with private bidders to devalue the assets." City officials won't comment.

Says Gaye Saroka, a local official of Waste Management, the nation's No. 1 trash company: "Trash got Orange County out of trouble. In San Diego County, it got them into trouble."

BUSINESS BRIEFS

Exchanges Stop Trading Baesa After News of Negative Net Worth

By Nikhil Deogun
Staff Reporter of The Wall Street Journal

Baesa Aires Embotelladora SA, a financially imperiled PepsiCo Inc. bottler in Latin America known as Baesa, said the Buenos Aires stock exchange has suspended trading of the company's stock after fiscal second-quarter results showed a negative net worth under Argentine accounting principles of $18.7 million.

The New York Stock Exchange also halted trading in Baesa's American depositary shares. Baesa, based in Buenos Aires, said it expects to meet with both exchanges to discuss the situation.

On Friday, debt-laden Baesa posted a loss of $29.1 million, or 40 cents a share, on sales of $182.8 million for the quarter ended March 31. For the year-earlier quarter, Baesa posted a loss of $26.4 million, or 36 cents a share, on sales of $206.8 million.

Last month, Baesa said a standstill agreement with creditors lapsed, leaving the company in default on about $505 million in debt. The bottling company has been discussing a restructuring plan with creditors, which include units of Citicorp's Citibank, BankBoston Corp. and Germany's Bayerische Vereinsbank. Although Baesa's operating performance has improved recently, it isn't generating anywhere near enough cash to service its $765 million in total debt.

In its earnings report, Baesa said it is "critical" that the company reach an agreement with creditors. If no agreement is reached before next January's shareholders meeting, Baesa said its board will have to consider several options, including filing for "insolvency."

"This either means they are going to use this as a posturing tool with creditors or they really may be under pressure from Argentine [regulators] to file for insolvency," said Maria Marron, an analyst for ING Barings in New York.

PepsiCo, based in Purchase, N.Y., owns 24% of Baesa and took voting control last May when the bottler was overwhelmed by losses stemming from a rapid expansion into Brazil. PepsiCo last year wrote down its investment in Baesa to a "prudent level."

Baesa's ADRs fell 15%, or 25 cents, to $1.375 apiece in New York Stock Exchange composite trading Friday.

Baesa attributed poor second-quarter results to debt, and other restructuring expenses of $18.6 million. The expenses comprised an $8.5 million write-down of a Costa Rica investment and $2.1 million in other restructuring charges.

FLAGSTAR COS.

Widened Loss Is Posted For Fiscal First Quarter

Flagstar Cos., reflecting mixed performance in its various restaurant chains, posted a widened loss of $51.7 million, or $1.38 a share, for its fiscal first quarter ended April 2. In the year-earlier quarter, the Spartanburg, S.C., company had a loss of $27.3 million, or 73 cents a share. The restaurant concern, which is shouldering $2.2 billion in debt, filed a registration statement with the Securities and Exchange Commission in March covering a restructuring, and said it expects to record a charge in the second quarter. Revenue rose 3.5% to $1.04 billion from $1.01 billion.

TRONICS MARKETS.

For the three months ended March 31, the Barrington, N.J., company, which publishes hand-held electronic books, said net was $311,000, or four cents a share, compared with $1.5 million, or 19 cents a share, a year earlier. Revenue fell 16% to $17.4 million from $20.7 million. Franklin shares fell 62.5 cents, or 5.9%, to $10 in the New York Stock Exchange trading Friday. For the fiscal year, net fell 38% to $6.7 million, or 82 cents a share, from $10.4 million, or $1.25 a share. Revenue fell 12% to $88.7 million from $100.8 million.

SLANTS & TRENDS:AN ENDANGERED SPECIES?

AN ENDANGERED SPECIES? - Many curbside recycling programs could face extinction by state and local governments anxious to fill space at cheap "mega-landfills," a new survey of state recycling managers has found.

Dozens of local governments have been forced to scale back recycling programs and increase taxes because they had depended on tip fees at their landfill facilities, according to the survey, published in State Recycling Law Update Year- End Edition. The survey also found that such economic incentives as "carrot and stick" tip fee surcharges and volume-based fees for trash seem to work best in encouraging landfill diversion; that many states are beginning to realize the need to address commercial, construction and demolition waste; and that there is widespread support among state recycling managers for phasing our subsidies for virgin materials. APPROACHING AN INTEGRATED SOLID WASTE MANAGEMENT SYSTEM FOR LOS ANGELES COUNTY, CALIFORNIA

EXECUTIVE SUMMARY

Throughout the nation there is growing controversy regarding the best approach for managing the millions of tons of waste generated by residents, businesses, and industries in large urban areas.

Pressures from both the public and private sectors have been successful in focusing attention on recycling and other alternative methods for managing of solid waste. As a result, a number of new statutes throughout the nation have been enacted to minimize reliance on landfills. California adopted Assembly Bill 939 (AB 939), the California Integrated Waste Management Act, in 1989. This act mandated that by 1995, 25% of the waste stream in each of California's counties had to be diverted from landfills. Furthermore, the act required that this diversion rate be increased to 50% by the year 2000. Diversion is defined as the process of diverting solid waste away from landfills through source reduction, recycling, and composting.

One year prior to enactment of AB 939, Los Angeles County developed a Solid Waste Management Action Plan (1988) which explicitly called for 50 years of in-county landfill capacity and minimized diversion potential. Six new in-county landfills were proposed in this Action Plan. In spite of the new legislative mandate to increase diversion of waste from landfills, as well as rapidly advancing technology which enabled the capacity of existing landfills to be expanded, Los Angeles County persisted in emphasizing landfills as the primary means of solid waste disposal.

Clearly an independent analysis of Los Angeles County's public policy on solid waste disposal was needed. This report provides another perspective to a "landfills first" policy, based upon carefully studied data projected in alternative "scenarios" by the authors. The Board of Supervisors could consider this document in their decision making process to comply with AB 939, as well as to preserve urban land for alternative uses.

These scenarios describe how Los Angeles County can implement strategies to increase regional interest. The goal is to divert more than 50% of the County's trash away from urban land and add years to the final life of the existing landfills in the County.

WHAT ARE THE OBJECTIVES OF THIS REPORT?

1. To offer alternatives to the Board of Supervisors and the public for urban landfills.
2. To provide suggestions for extending the life of existing landfills.
3. To foster a policy consistent with AB 939 to divert solid waste away from landfills.

This report paints a different picture of the future of solid waste disposal by making the following points:

- The document presents a strategic approach for addressing short and long term solid waste disposal requirements. The key to implementing the approach involves selecting the appropriate combination of alternative scenarios.
- By selecting a series of proven low risk alternatives (such as shown in Scenarios 1-5) for immediate implementation, the County's short term 15 year "time to crisis" is alleviated.
- Adoption and implementation of additional policy alternatives as recommended in the report enables the County to develop waste disposal policy well beyond the AB 939 planning period.

WHY DOES THE COUNTY DRAW DIFFERENT CONCLUSIONS FROM THE SAME DATA?

To illustrate the potential impact of creating a new diversion policy in Los Angeles County, the authors of this report developed a computer model which allocated the waste generated in the County among diversion and alternate disposal options. Prior to developing a model, the report presents a comprehensive review of two County sponsored documents; the 1996 Siting Element and the 1995 Draft Environmental Impact Report/Draft Environmental

Impact Statement (DEIR/DEIS) for Elsmere Canyon. The County has relied upon these two documents to sustain their current landfill policy.

A review of the County's reports reveal that they exaggerated the projection of waste generation and the need for additional landfill capacity. When critically analyzed, there is a clear discrepancy between the two documents regarding the amount of waste generated per day.

The Siting Element projects waste generation per day for 1997 to be some 4,200 tons more than the DEIR/DEIS document. The County has employed the higher estimate presented in the Siting Element document, thus accelerating their claim that additional new landfill capacity is required or the "time to crisis" is imminent. The computer model projects the quantity of waste disposed of in landfills located in Los Angeles County beginning in 1996 and running through 2044. The model evaluates waste disposal through the use of a series of waste management strategy scenarios. Each scenario develops a series of diversion alternatives aimed at increasing the life of in-county landfills.

SCENARIOS

The following summarizes the seven computer generated scenarios found in this report. Each scenario provides waste management strategies aimed at diversion such as recycling and composting, which will ultimately increase the life of existing in-county landfills. These scenarios can operate independent of one another, but in the analysis Scenarios 1-5 have been combined to have a cumulative impact. The impacts of the scenarios are shown graphically in Figure E-1.

SCENARIO 1—HISTORIC RATES

The County's solid waste strategy found in its Siting Element, the Base Case, calls for a minimum diversion of 50% as required by AB 939 and disposing the remaining waste in landfills.

Scenario	Waste Diversion and Disposal Policies	Projected Landfill Shortfall Date (Cumulative)	Years Added to Landfill Capacity
Base-Case	LA County Public Works' latest baseline for waste generation, rate of landfill use, and recycling (50% only from 2000), found in the Siting Element.	1999	N/A
1	The County's latest base-case with the historic use (daily disposal) rate of landfills, not the theoretical maximum rate.	2001	2
2	Include a net waste export of waste to Orange County landfills (which began January 1996) of 3,500 tons per day in 1997; rising to 6,000 in 2001 through 2026.	2007	6
3	Increase recycling of inert materials like construction and demolition debris (C&D), and divert remainder to the proper inert materials landfills, and away from Class III landfills from 1996.	2009	2
4	Incorporate the impact of LA City for 70% waste diversion (recycling, composting) by 2020 for the County Unincorporated areas as well as LA City.	2010	1
5	Use space-saving chemical/foam cover instead of dirt as the cover added daily to landfills, on all LA County landfills from 1997.	2014	4
	In addition to Scenario 5, one or both of the following:		
6A	Intensive diversion and recycling: adopt and implement the 70% waste diversion rate by 2020 for all of LA County and its 88 cities (residential, commercial, industrial).	2016	2
6B	Intensive diversion and recycling: add a ban on recyclable materials -- wood, corrugated paper and yard waste -- from landfills starting in 1998.	2019	5

	Effect of Additional Policies:	Years Added to Scenario 5
7	Assume no increased waste diversion, but expand five of the existing landfills to around half the level proposed by the County; no new landfills.	6
--	Use the conservative waste generation growth projections based on accurate, LA County specific data.	3

Figure E-1. Summary of Policy Options to Increase Diversion and Provide Adequate Disposal Capacity for Los Angeles County

Contrary to the County Siting Element figures which overestimates by using Daily Permitted Capacity numbers, this scenario utilizes more realistic figures based on a landfill's historic usage. This recalculation delays the supposed Daily Disposal Capacity Shortfall or "time to crisis" until the year 2001, two years past the County's original estimate (2 years).

SCENARIO 2–EXPORT ADDITION

The County's Siting Element does not account for existing export of L.A. County waste to Orange County. This scenario accounts for this export at a rate of 2,000 Tons Per Day (TPD) based on existing contracts in 1996 and 3,500 TPD starting in 1997. Exports are raised to 6,000 TPD in the years 2001 through 2044. Thus, this scenario extends the time to crisis from 2001 to 2007 (6 years).

SCENARIO 3–INERT MATERIAL AND BIOSOLIDS BAN

This scenario would ban inert materials and biosolids (sludge) in Class III landfills. It is assumed that the inert ban would be 80% effective and the sludge ban 100% effective since the material is controlled by the County. If implemented, this scenario extends the time to crisis to the year 2009 (2 years).

SCENARIO 4–DIVERSION GOAL BY 70 PERCENT

This scenario calls for the County to join with the City of Los Angeles and adopt a goal of 70% diversion in all unincorporated County areas by the year 2020. The result would be an extension of Daily Disposal Shortfall (time to crisis) to 2010 (1 year).

SCENARIO 5–CHEMICAL/FOAM COVER

This scenario replaces the use of dirt to cover waste deposited daily in L.A. County landfills with a chemical or foam cover. The report assumes a daily foam or chemical cover is initiated in 1997. The saving capacity is 22%, allowing space for 22% more waste at each

landfill. Implementation of this technology will delay the Daily Disposal Shortfall until the year 2014 (4 years).

SCENARIO 6–INTENSIVE RECYCLING AND DIVERSION

Two different model scenarios were conducted, both of which are mutually exclusive to the other.

6a. Total County 70% Diversion. Assumes all cities and the unincorporated areas of Los Angeles County achieve 70% diversion by 2020. Starting in 2001, the impact would increase diversion by one percent per year, extending the shortfall to the year 2016 (2 years).

6b. Recyclable Material Ban. Assumes a ban of corrugated wood and yard waste in Class III landfills beginning in 1996. The ban would be 70% effective and postpones the Daily Disposal Shortfall until 2019 (5 years).

SCENARIO 7–LANDFILL EXPANSION

This scenario was added not to propose landfill expansion but to put in proper context for policy makers the comparative results achieved by focusing on a reduce/recycle/compost strategy. Implementing Scenarios 1-6 is relatively low cost and politically risk-free compared to the cost of landfill expansion. It also illustrates that 24 years of capacity can be realized by these methods. Further ample time is realized for emerging alternatives such as rail haul to take effect and further alleviate the pressure for landfilling of waste within the County. This strategy must be enacted in conjunction with Scenarios 1-5 to postpone the Daily Disposal Shortfall until 2023 (9 years).

HOW CAN LOS ANGELES COUNTY CREATE AN ALTERNATIVE WASTE DISPOSAL POLICY?

In this report a number of different alternatives to extend existing landfill capacity are examined. Clearly, if the County adopts these alternative strategies there is no need to develop

new landfills anytime in the near future. In order to implement these alternatives Los Angeles County will have to shift its waste management strategy and place more emphasis on recycling and diversion *as required by law*. Further, the County should realize that its self-imposed requirement of 30 years in-county disposal capacity may have a serious legal flaw. The courts have recently ruled in-county disposal unconstitutional.

The first step is for the County to develop a new policy which outlines the process of diverting solid waste away from landfills through source reduction, recycling and composting. Once the policy is adopted, the County will become responsible for implementing and ensuring the process of diversion. Specifically, the County should:

- Develop a diversion strategy;
- Adopt billing and accounting methods for solid waste that fully account for all cost items;
- Set new diversion goals for the County's unincorporated areas, and to monitor and report on the achievement of these goals;
- Coordinate and facilitate diversion programs with the County's 88 municipalities;
- Provide incentives between the public and private sectors to increase the participation in County-wide diversion programs; and,
- Function as a role model to the cities by developing a model recycling program for all County facilities, as well as implementing a County-wide "reduce-recycle" advertising campaign.
- Review legality of flow control ordinances or other restrictions on waste flow in the County.
- Develop detailed costs for implementation of the new policy.[1]

[1]Detailed cost analysis of diversion options was beyond the scope of this study.

CONCLUSION

It is the conclusion of this report that Los Angeles County can effectively meet and exceed AB 939 requirements without opening new landfills. Indeed, by leading its 88 municipalities and the unincorporated areas into the 21st century, Los Angeles County can be the facilitator to implement an effective regional diversion-oriented solid waste disposal policy. However, the County must act now.

I. INTRODUCTION AND PURPOSE

The impetus for the development of this document arises from sincere concerns about the potential environmental, aesthetic, and social consequences of Los Angeles County's policy of developing in-county landfills for solid waste management. The County's promotion of the new Blind, Elsmere Mission/Rustic-Sullivan and Towsley Canyon landfills provides examples of this. The authors and many individuals and groups in the County feel strongly that there are better ways of managing the rubbish of our society than vast storage piles that must be engineered, managed, and monitored for 80 to 100 years, and, in the process, destroying pristine canyons with their wildlife, waterfalls, and opportunity for open space recreation in an increasingly urbanized area. The alternative vision is a diversion-based policy that applies the full array of modern solid waste management technologies that together can reduce, reuse, and recycle as much of the solid waste generated by the residents and businesses in the County and the 88 cities as possible, and transform or safely dispose of the remainder.

Approaching an Integrated Solid Waste Management Plan for Los Angeles County was prepared by Gershman, Brickner & Bratton, Inc. (GBB), a national consulting firm that specializes exclusively in solid waste management. GBB's professional staff consists of engineers, planners, economists, environmental scientists, market analysts, and recycling and community relations specialists. GBB was assisted in this effort by a distinguished team of individuals who provided unique perspectives on Los Angeles County issues. They are:

- Joan Edwards, of J. Edwards & Associates, former Director of the Integrated Solid Waste Management Office for the City of Los Angeles Board of Public Works.
- Eugene Tseng of E. Tseng & Associates, a nationally-recognized environmental engineer and member of the California bar who has provided technical services to the State of California as well as technical oversight for the City of Los Angeles' AB 939 Solid Waste Generation Study. Eugene Tseng is also an Adjunct Professor at the UCLA Anderson Graduate School of Management.
- J. Eugene Grigsby, III and Leobardo F. Estrada of UCLA. Eugene Grigsby is president of The Planning Group in Los Angeles. He is also a professor at UCLA's Graduate School of Public Policy and Social Research, where Leo Estrada is an associate professor. Dr. Grigsby and Dr. Estrada provided essential population and demographics data for Los Angeles County.

It is not intended that this document serve as a detailed Integrated Solid Waste Management Plan for the County of Los Angeles – the County Plan (presently in preparation) that pulls together all the Source Reduction and Recycling Elements (SRREs) developed by the County and the incorporated municipalities is intended by California's AB 939 law to be a very specific, implementable Integrated Plan. The components needed for such an implementable plan that are not available in this document are:

- Verifiable quantification and characterization of waste actually generated in Los Angeles County (including materials presently diverted, both reported and estimates of unreported): As discussed in later chapters of this document, the County's projections of waste generation are inconsistent, and based on dubious assumptions.
- Determination of leadership and the roles of the public and private sectors: The County's present posture is that it has limited influence over future development of solid waste management. However, the County is responsible under AB 939 for developing the overall County Plan, and this requires commitment and leadership.
- Reorganization of the County's management structure to accommodate reduction and recycling as an integral part of the County's activities: This is not solely a responsibility of the incorporated municipalities and the private sector.
- The essential public input to the development of a Plan: While this document is an exhaustive review of current trends and techniques, it has not been through the extensive public review, public hearing, and comment process that is necessary for a community to claim a Plan as its own.
- Develop detailed costs for implementation: The changes in policy recommended will change the costs of solid waste management in the County. The cost increases and savings will need to be determined by the County and the Cities.

Instead, this document is meant to inspire a profound change in the County's *status quo* approach to solid waste management exemplified by the County's support for the proposed Elsmere Landfill. The County's historic policy emphasizing landfill capacity must adapt to present reality, which places pollution prevention and diversion first. In the following chapters, this document lays out the complex parameters defining solid waste management from now

through the turn of the Century, reviews alternative technologies and management structures, and recommends actions for implementation by the County and the 88 cities.

This report incorporates the dramatic changes experienced in the field of waste reduction/recycling in recent years. Since the SRREs were prepared in the early 1990s, technologies have improved, new markets have developed, existing markets have expanded, and the overall economics of waste diversion are increasingly positive. The County believes that addition of huge new landfill capacity in the County promises to maintain competition for disposal, and thus will keep disposal costs down. However, cheap disposal is only one factor to consider in developing an integrated solid waste management program, including source reduction, recycling, collection, transfer, and composting. Landfills have hidden potential costs if cleanup actions are necessary. On the other hand, diversion has no such future costs and provides the current benefits of local jobs and raw materials for new or existing industries.

Finally, this document is not a pie-in-the-sky fantasy of an ideal world. GBB is well aware of the limitations of current practices. Some waste will remain that must be managed by traditional disposal methods (i.e., landfilling). However, that is not a reason to rely on landfills as the primary approach to solid waste management. The alternative technologies and management structures outlined here are all practical, tested approaches presently in use by local governments across the nation, and real-life examples and a Case Study provided. Not one of the recommended approaches is new or revolutionary nor does any single component represent a "magic bullet" for solid waste management. Together, however, these recommendations represent a dramatic shift in vision, offering the County of Los Angeles, the 88 cities, and their inhabitants the opportunity to chart the future of integrated solid waste management and environmental preservation.

II. HISTORY OF SOLID WASTE PLANNING IN LOS ANGELES COUNTY

Los Angeles County is the most populous local jurisdiction in the United States. The population in 1995 was 9.3 million people of diverse cultural, social and economic backgrounds. This population has been growing rapidly in the last decade, with the growth rate doubling from the previous decade's annual growth rate of half of one percent to the current decade's growth rate of over one percent per year. The County covers an area of approximately 4,100 square miles and is comprised of 88 cities and a large unincorporated area. Economic activity is as diverse as the population and includes manufacturing (aerospace, electronics and automobiles), entertainment, oil and food processing industries. The Port of Los Angeles is one of the busiest ports in the country and serves as the major connection between the U. S. and Japan and the other Pacific Rim countries.

The size and diversity of Los Angeles make solid waste management planning a large and complex undertaking. Each of the 88 cities and the County play a role in the collection of the solid waste generated in the County. These roles range from permitting of private collectors to operating large collection operations. In addition, there are in excess of 250 private firms that collect solid waste in the County.

After World War II, solid waste management was mainly an individual and community problem. Many residents burned their waste in their backyards. The waste that was not burned was taken to community or private dumps, some of which practiced open burning as well. Beginning in the early 1950's, the Sanitation Districts of Los Angeles County (Sanitation Districts) initiated planning for solid waste. In the late 50's, the Sanitation Districts working jointly with the County, sited and developed five landfills and a transfer station to improve the quality of solid waste disposal and end open burning. These facilities were implemented under a series of joint powers agreements and funded by the County and the individual Sanitation Districts. Planning and policy formulation was done jointly. In the mid-1960's, the County and the Sanitation Districts established a joint trust fund and adopted the policy of setting rates at the landfill operations with the intent of both paying for operations and developing a surplus with which to expand existing facilities and acquire new facilities. In 1970, the various Sanitation

Districts pooled their resources and established a joint transfer and disposal system, operated by County Sanitation District No. 2. The County and the Sanitation Districts believed they had planned and implemented an excellent system; it was, however, one that would quickly prove to be inadequate for the waste generated in the County. In the early 1970's, materials and energy recovery as alternatives to landfilling were considered and rejected as unproven and expensive.

In 1972, the Legislature passed the California Solid Waste Management and Resource Recovery Act. This Act created the California Solid Waste Management Board to oversee solid waste management policies and programs in California. The 1972 Act assigned primary responsibility for solid waste management plans to the local governments. County solid waste management plans were the result. The state was responsible for statewide policy, approving county plans, providing technical and financial assistance, overseeing enforcement, inventorying disposal sites, and developing a state solid waste management plan. The California Solid Waste Management Board (CSWMB) developed five principles for solid waste management under the 1972 state policy:

1) Solid waste management must be planned and conducted in an economical and environmentally sound manner;

2) Solid waste management must be consistent and in compliance with state policy, county plans, and minimum state standards;

3) Solid wastes need to be reduced to conserve energy, natural resources, and land resources;

4) Material and energy recovery from wastes is to be encouraged; and

5) Adequate litter programs are needed to ensure environmental quality and public health, safety, and well-being.

The counties were required to adopt and maintain solid waste management plans which evaluated resource recovery options, and implement recovery programs which limited the dependency on landfill disposal. The CSWMB prepared planning guidelines and procedures for preparing these plans, including procedures for revising and amending plans. The CSWMB also

developed minimum standards for solid waste management. These standards still govern disposal in the state and were enforced by both the state and local governments. The CSWMB promoted waste-to-energy facilities as an alternative to landfilling in California. The CSWMB felt that a solid waste management "crisis" was real and that Southern California would run out of landfill space by 1982.

In 1976, the Solid Waste Control Act was enacted, requiring permits for landfills and transfer stations. The Act also required cities and counties to establish a local enforcement agency to enforce the permit requirements and the other provisions and regulations called for in the Act. The Department of Health Services was designated as the enforcement agency for solid waste facilities in the County.

As mentioned, the 1972 Act required local jurisdictions to develop a solid waste management plan in cooperation with cities and private industry. Los Angeles County developed its plan and the Board of Supervisors adopted it in 1976. It was approved by the CSWMB in 1977. Since that time, the County has reviewed and updated the plan, as required, several times. The current plan, the Los Angeles County Solid Waste Management Plan (the Action Plan), is dated March 1984. This, along with Revision A (August 1985), is the official document currently governing solid waste management planning in the County. The Action Plan set out the goal of developing a solid waste management system that minimized the quantity of waste produced and disposed in the County by source reduction, recycling, waste-to-energy, and/or new technologies.

Few of the goals enunciated in the Action Plan were ever realized. The waste-to-energy goals encountered strong public opposition and only two of the planned facilities were constructed. Source reduction and recycling also lagged in their implementation. The County concluded that additional solid waste facilities were required for the projected future waste flows. As a result, the County along with the County Sanitation Districts initiated the Solid Waste Management Siting Project. This effort established criteria and guidelines for siting solid waste facilities (transfer stations, waste-to-energy facilities and landfills). In addition, a search for landfill sites was initiated. The County and the County Sanitation Districts alternative site

study group reviewed an initial list of 101 potential sites. From this list, six sites were selected -- including Blind Canyon, Brown Canyon, Elsmere Canyon, Mission/Rustic-Sullivan Canyons, Towsley Canyon, and Toyon II.

In April 1988, in order to further the goals of the siting efforts, the Solid Waste Action Plan was developed. This document -- ironically containing source reduction, recycling and composting elements -- primarily focuses on landfills. The Action Plan calls for 50 years of landfill capacity held in public ownership. To achieve this goal, the Action Plan supports the expansion of existing landfill and the development of new landfills. The six sites selected in the alternative site study have been reviewed for feasibility and four have been determined to be feasible: Blind, Elsmere, Mission/Rustic, and Towsley Canyons.

In 1989, the California Integrated Waste Management Act was passed by the Legislature and signed into law. This Act (AB 939) revised the framework for solid waste management planning in the state. Most significantly, AB 939 established a hierarchy for the management of solid waste. It requires local jurisdictions to divert solid waste from landfills through source reduction, recycling, and composting. AB 939 also establishes clear mandates for diversion: 25 percent in 1995 and 50 percent in 2000. In addition to requiring cities and counties to prepare specific planning documents that demonstrate how the diversion mandates will be met, the Act revised the state level review and planning processes and established the California Integrated Waste Management Board (CIWMB).

In summary, the County of Los Angeles solid waste management planning, in the opinion of this report, is focused primarily on in-County landfill. The County's policies reflect this orientation of the Action Plan, which, until superseded, still has the force of law.

III. RATIONALE FOR A NEW APPROACH TO COUNTY SOLID WASTE MANAGEMENT PLANNING

This chapter summarizes the complex history of solid waste management in the U.S. as it has evolved over the last twenty-five years and its relevance to practices. Striking changes in our attitudes toward, and handling of, municipal solid waste have occurred during this period. In this context, it is necessary for Los Angeles County and all of its 88 cities to catch up with the times. The public demand for change is clear, resulting in new laws, new technologies, and new economics of solid waste management. It is entirely reasonable to assume that this pace of change will continue in the next twenty-five years.

A. PUBLIC DEMAND

The development of recycling and improvements in disposal technology in the United States is largely the result of grassroots efforts. Beginning with Earth Day in 1970, the general public has become more and more aware of their environment. This awareness has been heightened by environmental and conservation organizations' efforts at public education. The battle cry of these efforts has been, "We are a throw-away society -- the most wasteful nation on earth." Out of this point of view came the question, "What can one individual citizen do to make a difference in such a complex society?" The answer came clear, "I can recycle. I can control my own trash and I can conserve resources."

This attitude fostered volunteer recycling drop-off centers, such as the one in Berkeley, California that started in the early 1970s. With the growth of such centers, volunteers realized the need for wider participation and statewide coordinated efforts. This realization produced demand for legislated local and state recycling goals, with the result that most states now have enacted recycling laws. This trend continues. A survey conducted for Waste Management Inc. in 1995[7] indicates that 63 percent of consumers favor stricter recycling laws and 85 percent feel recycling is here to stay.

[7] "Attitudes and Behavior Regarding Recycling," The Gallup Organization for Waste Management, Inc., March 1995.

B. POLICY SHIFTS

The first statewide recycling law was passed in Oregon in 1983. Today, a total of 41 states have passed recycling legislation. Initially, most of these state laws set a statewide goal to be achieved by the local jurisdictions responsible for solid waste management. These goals stated a percentage of the solid waste to be recycled or diverted by a specified year. Originally, legislation left determination of the methods to attain goals up to the local jurisdiction. However, policies have shifted toward a mandatory requirement in about half the states, and many individual communities in states with voluntary goals are also choosing mandatory practices.

The federal government, after largely ignoring solid waste for a decade, shifted to a recycling-oriented policy reflected in their integrated waste management hierarchy: source reduce, recycle (including composting), combustion (with energy recovery) and landfilling. This integrated approach was first enunciated in *The Solid Waste Dilemma: An Agenda For Action* published by the U.S. Environmental Protection Agency (U.S. EPA) in 1989. This report stated a national goal of 25 percent recycling by 1992. This policy shift at the federal level was paralleled by additional shifts at the state and local levels. Many jurisdictions shifted from recycling goals to the broader requirement of reduction and diversion, instituting bans against landfilling specific materials including yard waste, tires, batteries, white goods (i.e., large appliances), waste oil and other specific materials. Some communities passed legislation banning the sale of products made of hard-to-recycle materials (e.g., foam plastic fast food containers). However, many of these bans were rescinded as markets became available or because of court challenges by manufacturers.

As discussed in Chapter II, California passed AB 939 in 1989. This law changed the focus of solid waste management from disposal to diversion by establishing a hierarchy which places landfilling on the lowest tier and setting diversion statewide goals of 25 percent by 1995 and 50 percent by 2000.

More recently, increasing recycling goals is one policy trend that is apparent. For example, New Jersey raised the original 25 percent reduction/recycling requirement to 60 percent in 1992. The City of Los Angeles has set a 70% diversion goal and Alameda County has set a goal of 75%. Also, realization has set in that removing materials from the waste stream alone is not enough. This realization is resulting in efforts to develop or expand markets for materials, and to contribute to the development of markets through purchase of products with recycled content. Laws and ordinances are being passed designed to encourage market development, and "Buy Recycled" programs are increasing nationwide.

Policy shifts have occurred in the private sector in concert with the grassroots demand for change. New laws to protect the environment have been passed and new technologies have been developed in the environmentally aware industries. The paper industry, for example, initially adopted a goal of recycling 40 percent of the waste paper generated each year in the U.S., then raised the goal to 50 percent. Browning Ferris Industries (BFI), a leading national solid waste management company, committed its resources to recycling. As a result, BFI has become the world's largest recycling firm. Thousands of businesses throughout the U.S. have invested billions of dollars in infrastructure to separate, process and utilize recycled materials.

A policy shift being implemented in Europe is the producer responsibility or the "take it all back" system. This system shifts the responsibility for recycling and disposal of products, particularly packaging, to the manufacturer or producer. This approach is being discussed in the United States and the business sector is strongly opposed. Implementation on a nationwide, not state or local basis, seems to make the most sense as is illustrated by the experience in Europe. Producer responsibility is discussed in Appendix A.

In this climate of policy shifts toward recycling from the grassroots to all levels of government, business and industry, Los Angeles County needs a policy shift to a proactive integrated waste management policy approach that places a priority on diversion.

C. DIVERSION TECHNOLOGY

As recycling and diversion policies changed, approaches to collecting recyclables evolved beyond the Berkeley-style volunteer drop-off center. The solid waste stream, originally viewed as a heterogeneous mass, is now divided into generator sectors (residential, commercial, institutional and industrial), product categories (tires, white goods, yard trimmings, batteries, etc.) and materials (ferrous metals, glass, paper, etc.). This fractionating is due to the needs of the diversion industry as well as the unique manner in which certain waste stream components (such as tires, rechargeable batteries or household hazardous wastes) must be managed in order to reduce the impacts on landfills.

The industrial segment of the economy has discovered that, in many cases, pollution prevention (i.e., not producing a waste in the first place) not only saves money on waste management but lowers the cost of product manufacture. This trend in the manufacturing sector caused a severe economic decline in the hazardous waste management industry. As the environmental regulations tightened during the 1980's due to RCRA and other requirements, the industry developed disposal facilities including hazardous waste incinerators and "secure" Subtitle C landfills. The price charged for hazardous waste disposal rose to cover the cost of these investments and their operation. The increase in disposal fees caused the generating industries to take a hard look at the "generate and dispose" policy. The result, in many generating industries, was a change in policy to pollution prevention. This policy focuses on examining industrial processes or the way products are made, then making changes in these processes to reduce the waste discharge. Many industries found that this not only reduced the cost of waste disposal allocated to a product, but improved the product quality.

The recycling industry, both public and private sectors, has found that recycling costs can be reduced if some individual waste components are never mixed in with the waste stream. This means changing the behavior of the individual waste generator in the home, office, business, and industry, so that different materials are placed in specific containers. The custodial, waste collection and waste processing functions require changing as a result. This change in behavior can be motivated by ethical, economic or cultural factors. It can occur spontaneously or by

design. The process is accelerated when there is an overall vision or policy, such as that stated by AB 939.

This source-separation eliminates some sorting and contamination clean-up steps. Chapter VII and Appendix B discuss separation technologies that have evolved. At the same time, sortation and clean-up technology has developed to the point where, for example, plastic containers can be economically sorted mechanically into individual resins. The pace of these developments is accelerating, and solid waste management planning should take this trend into account.

Implementation of technology requires investment. In the past decade, there has been a very large investment in the infrastructure necessary to implement diversion and recycling. For example, communities have made a multi-billion dollar investment in recycling collection and processing infrastructure. The paper industry has invested billions in existing plants and building new ones to accept and process recovered paper. Other industries have decided to use recycled materials to make new products and have modified processes and plants to utilize new feedstocks. In addition, communities and states have made major investments in market development. These include tax breaks, grants, and financing to businesses that utilize recovered materials, as well as siting, permit expediting, and other facilitation services. As a result, both the supply and demand portion of the markets for recovered materials looks positive, as discussed in Chapter VII. Investment and market structures are projected to improve in the future and these trends also impact solid waste management planning.

D. LANDFILL PROBLEMS

New landfills, as well as other solid waste facilities, have become difficult to site in urbanized areas. People living in or near a potential site area, and the businesses located there, have legitimate concerns based on the inherent nature of these facilities and their impacts. These include: truck traffic, noise, dust, odors, litter, and air and water pollution. Large facilities compound these characteristics, increasing their impacts in a non-linear fashion. These reasons alone are sufficient for a community to object to the siting of a large MSW landfill facility in

or adjacent to the community. While recently adopted laws and new technologies are designed to control environmental impacts, the performance of old landfills and dumps that are releasing air and water emissions without mitigation, promoting rats and other vectors, and contain hazardous wastes serve as a basis for community protests against these facilities. As landfills compete in urban and suburban areas with other land uses, these concerns will make siting landfills more difficult and expensive.

Modern landfill technology, including multi-layer liners (using plastic membranes and clay), leachate collection and treatment, methane gas collection, monitoring wells and cover requirements, is designed to address the problems presented by old dumps. However, the technologies are new and long-term performance data is not yet available. This presents problems in predicting the long-term impacts of landfills. For example, data on large-scale liner failure in a landfill containing 50 million tons of waste (e.g., Elsmere after 10 years of operation at design capacity) does not exist. Such a failure, whether due to technical or seismic problems, could result in correspondingly catastrophic groundwater contamination and other impacts. This makes estimating the cost of long-term operations and post-closure care difficult and subject to unproven assumptions.

The technical cost is not the only consideration. Once failure occurs and environmental damage results, litigation is initiated to determine liability among the owners, operators, and users. Legal costs (based on Superfund experience) are likely to exceed remediation costs. In addition, as discussed in Chapter VI, the human health risk from air emissions from landfills is greater that of waste-to-energy facilities.

E. CHANGES IN LANDFILL MANAGEMENT

New landfill management techniques have been developing over the past decades. These approaches have arisen in part to avoid some of the landfill management problems discussed above, such as application of daily cover materials to control odors, litter and vectors and to prevent landfill fires. Another driving factor in management changes is the need to conserve landfill capacity as a result of the difficulties encountered in siting new landfills or expanding

existing fills. The experience and potential for conserving or using landfill capacity most efficiently is discussed in Chapter VI and Appendix C. The pressures to innovate landfill improvements are accelerating in all the urban/suburban areas in the country, and in many rural areas as well. Implementation of appropriate landfill conservation management techniques need to be factored into landfill planning in Los Angeles County.

F. ECONOMICS

These trends impact the economics of solid waste management. These impacts are quantum changes, rather than incremental. For example, when communities first implemented curbside collection of materials for recycling, the initial result was a 10 to 15 percent diversion of the residential waste stream. The collection of recyclable materials from each household was implemented with new trucks and staff increased costs. Refuse collection costs, however, remained the same, even though the collected quantity dropped slightly. Communities were paying for two parallel collection systems. However, increasing diversion to 50 percent requires an entirely new system. This new system includes new containers, levels of service, trucks, personnel requirements, management strategies and fee structures. Chapter VII discusses many examples. The south half of City of Seattle contracts weekly automated waste collection, once per month automated recycling collection, and separate weekly yard waste collection. This Seattle system reports 55 percent recycling. The north half of Seattle contracts with a second vendor that uses a different system, recovering slightly less of the waste stream. To provide incentive for diversion, the City Solid Waste Utility charges a variable rate fees to households, operates as an enterprise fund, and uses a full cost accounting methodology to set these fees. Seattle's variable rate is based on the size of the waste disposal container requested by a household, with a total monthly cost of less than $10.00 to a household using the smallest size container. No fee is charged for recycling and yard waste collection. (See Appendix D for a description of Seattle's program and Appendix E for a discussion of enterprise funds and full cost accounting.)

Variable rate fees (either by container size as in Seattle or by weight of the disposed material) have been shown to reduce the total quantity of waste generated. Many communities

are not benefiting from the economies available from rationalizing their collection systems in keeping with the integrated waste management philosophy. These potential savings coupled with the potential revenues from recovered materials should be included in solid waste planning.

Nationwide, the trend in the cost of landfill construction and operation is upward as a result of increasingly stringent federal and State requirements. The cost of constructing new cells and landfills includes liners; leachate collection, storage, treatment and detection; and gas collection and processing and monitoring required by recent federal and State regulations contribute to this trend. Also, the cost of closure and post-closure maintenance add additional disposal cost, as the projected costs for these expenditures must be raised during the active life of the landfill. New rules have closed smaller, inefficient landfills, and encouraged the development of very large landfills that can spread higher development and operation costs over a greater tonnage of waste.

This rising cost trend appears to be in conflict with the short-term trend of lower tipping fees at various landfills in the Los Angeles region. This local downward pressure is caused by excess capacity and increased competition for smaller quantities of solid waste. The result of this will be an industry shakeout and consolidation in southern California.

G. FLOW CONTROL

The County should recognize that the reliance on in-county disposal capacity may have a serious legal flaw. On May 16, 1994, the Supreme Court of the United States examined the constitutionality of local government exercise of preference for the use of a local transfer station for solid waste. In a majority opinion by Justice Kennedy, the Court pronounced a Clarkstown, New York ordinance requiring the use of a local transfer station unconstitutional, because it discriminated against out-of-town providers of disposal services. *C & A Carbone v. Town of Clarkstown*, 114 S.Ct. 1677, 128 L.Ed.2d 399 (1994).

Similar reasoning to the County's "in-county" capacity policy led the State of New Jersey and its Department of Environmental Protection to require each garbage district in the State to

provice for disposal capacity within the district or another district through agreements. The New Jersey plan, with its preference for in-state and in-district disposal capacity planning, was struck down by the United States Court of Appeals for the Third Circuit, in *Atlantic Coast Demolition*.

The Supreme Court decision in the *Clarkstown* case and the Third Circuit's decision in the *Atlantic Coast Demolition* case indicates that, to the extent that the County solid waste management plan relies on the Action Plan with its requirement for 50 years of in-county landfill capacity and ordinances which favor in-county disposal, it is subject to successful legal challenge.

H. CONCLUSION

The developments and trends touched on above make integrated waste management planning difficult and imperative. The current fluid situation provides Los Angeles County with an opportunity to provide the leadership and coordination needed to develop an integrated waste management system for the County and its 88 cities that will serve its citizens well into the Twenty-first Century.

IV. WASTE GENERATION PROJECTIONS

A. STATEWIDE AND NATIONAL TRENDS

The increase in waste generation rates projected in the Elsmere Canyon DEIR/DEIS and the Siting Element are inconsistent with California State Board of Equalization reports and EPA forecasts. "Time-to-crisis" estimates in the DEIR/DEIS assume a waste generation increase rate of 2.5 percent per year from years 1993 to 2000. The Siting Element uses the CIWMB Adjustment Methodology to project even higher waste generation for the Los Angeles County.

In *Characterization of Municipal Solid Waste in the United States: 1994 Update*, the U.S. EPA projects that the national per capita waste generation rate will decrease from 4.4 pounds per person per day in the year 1993 to 4.3 pounds per person per day by the year 2000. A May 1995 study prepared for the CIWMB[2] calculated that the amount of solid waste disposed in California each day was 5.9 pounds per person in 1993, compared to 7.9 pounds per person as of January 1, 1990, and 7.4 pounds per person per day as of June 1985. This shows a 20.3 percent reduction in the eight years between 1985 and 1993. The report speculates that, "(t)he reduction in disposal amount is generally believed to be the result of the start-up of many new recycling programs and the reduction in generation amounts because of a prolonged recession in California."

The most important data is local. California State Board of Equalization waste disposal records, when compared with California Department of Finance population figures, reveal a descending trend in per capita waste generation rates in Los Angeles County.[3] Also, this is consistent with the efforts toward source reduction on the part of the County and the 88 cities as enunciated in the SRRE's.

[2]*Toward Ensuring Adequate Landfill Capacity*, prepared by Environmental Science Associates for the California Integrated Waste Management Board (CIWMB), May 9, 1995..

[3]References for data sources and methodology are provided on Table V-1.

Table IV-1 presents waste generation projections for Los Angeles County based on California State Board of Equalization reports and California Department of Finance census documents. For years 1990 to 1994, actual Population figures and quantities of Waste Disposed were used in Table IV-1. Using the diversion rates projected by the County in the DEIR/DEIS, the annual tonnage of Waste Generated was calculated [Waste Generated = Waste Disposed / (1 - Diversion Rate)]. This daily Waste Generated was converted to pounds by multiplying by 2,000 and converted to a daily figure by dividing by 365 and divided by the Population to derive the Per Capita Generation rate for 1990 through 1994. Waste Generated was calculated by multiplying Per Capita Generation by Population and converted to a six day per week basis.

Beyond the year 1994, California Department of Finance Population estimates and Diversion Rates anticipated by the County were used. To project Waste Generated, the first step was completing a linear regression on the Per Capita Generation data for years 1990 to 1994. All Per Capita Generation figures below the single line on Table IV-1 represent data points on the linear regression line. Based on the regression, there is obviously a downward trend in Per Capita Generation, which is expected as public participation in source reduction and recycling continues to rise. This projection is reasonable for Los Angeles County given the demographic changes discussed below and it is consistent with EPA forecasts. The Waste Generated for all years beyond 1994 are calculated by multiplying the Per Capita Generation by the Population.

In the DEIR/DEIS, the County showed waste generation rates increasing by 2.5 percent per year from 1993 to 2000, and then by 1 percent per year for all years beyond 2000. One percent was the assumed annual population growth, and per capita generation was assumed to increase by 1.5 percent per year until the year 2000. However, Table IV-1, based on records from the California State Board of Equalization and the California State Department of Finance, reveals that these assumptions do not reflect the actual trends. The annual percent change in population is slightly more than 1 percent, but per capita generation rates are declining. The reasons for the lower waste generation trend are discussed in the next section.

In the Siting Element, the County projects waste generation using the CIWMB approved standard adjustment method. The Adjustment Methodology is built up from the 1990 (base year)

Table IV-1. County of Los Angeles Projections For Waste Generation and Disposal

Year	Population[1]	Percent Change in Population	Waste Disposed (Tons)[2]	Diversion Rate (%)[3]	Waste Generated (Tons)	Materials Recycled (Tons)	Per Capita Generation (Pounds/Day)	Waste Generated (Tons/Day)

[1]California Department of Finance, Demographic Research Unit, 1993 Population Projection Series; Because projections only completed until 2040, years 2041 – 2043 are based on 1% annual population growth estimate.
[2]California State Board of Equilization
[3]Los Angeles County Department of Public Works

waste generation figures in the residential and commercial sectors, and utilizes the projected residential and commercial sector ratios of population, employment, and taxable sales to compute adjustment factors, that are in turn used to project the waste generation in the year of interest.

EPA's report and the County's solid waste planning efforts both start with a projection of waste generation. In its past planning efforts, called "time to crisis" calculations in the DEIR/DEIS and the Siting Element, the County has developed a number of waste projections. Two of these are shown in Table IV-2: the first data column is from the 1996 Siting Element and the second data column is from the 1995 DEIR/DEIS[4]. Interestingly, the County's most recent projection shows an increase in the per capita waste generation rate. Table IV-2 provides a comparison between data from the waste projection discussed above, County historical data and a calculation based on the social and economic factors discussed in Section B of this chapter.

It is the conclusion of this report that the County's projections are high and exaggerate the need for landfill disposal capacity. Figure IV-1 shows graphically how the County's change in the projection method from the DEIR/DEIS in 1995 to the Siting Element in 1996 impacted the projected landfill need. The top curve is the current Siting Element projection; the middle curve is from the DEIR/DEIS; and the bottom curve illustrates the projection developed in this chapter. In the DEIR/DEIS, the projected quantities of waste generated per day are some 4,400 tons lower than the Siting Element, with the corresponding reduction in disposal need.

B. LOS ANGELES DEMOGRAPHIC TRENDS

Since the publication of the County Action Plan in 1988, Los Angeles County has seen its robust economy take a downturn and stagger with the loss of industries, jobs and wage growth. In the County, for example,

- There were 335,000 fewer non-agricultural jobs in 1994 than in 1988;

[3]Source: GBB.

- Unemployment in 1988 was hovering around 5 percent, but has since doubled to about 10 percent in 1994; and

- Jobs in the aerospace/high technology industries have declined by 45 percent, which translates to the loss of 125,200 jobs since 1988.

While the national recession was declared over in 1991 by the Council of Economic Advisors as other regions of the United States rebounded, in 1995 Los Angeles County remains mired in the recession with hopeful signs of weak upward swing to the end of the decade.

1. Economic Restructuring

Although not unique in undergoing restructuring from a manufacturing to a service and information based economy, Los Angeles is experiencing a far more rapid, intense, and complex transformation of its urban economy (Soda, Morals, and Wolf, 1983). In addition to the loss of aerospace jobs, employment losses hit a broad range of the County's economy. For example:

- The retail sector lost nearly 62,000 jobs, construction lost 3,000 jobs, public employment lost nearly 15,000 jobs, and the services sector remained about 10,000 jobs below its prior levels (Wolf and Grigsby, 1995).

- The value of two-way trade in the Los Angels Customs District, which grew by 13 percent during the 1988-89 period, rose by only seven percent in the 1994-95 time period.

- The County received 50,200 housing unit permits in 1988, but only received 25,300 in 1994, a decline of 50 percent.

2. Changing Demographic Climate

Los Angeles County continues to grow, from 7,477,400 people in 1980 to 8,863,200 in 1990 to an estimated population of 9,194,400 in 1993. The annual rates of growth have declined from about 1.6 percent a year from 1980 to 1990, to 1.2 percent since 1990. More importantly, Los Angeles County has undergone a dramatic shift in its ethnic composition since 1988. White-Nonhispanic share will decline from 41 percent in 1990 to 33 percent in the

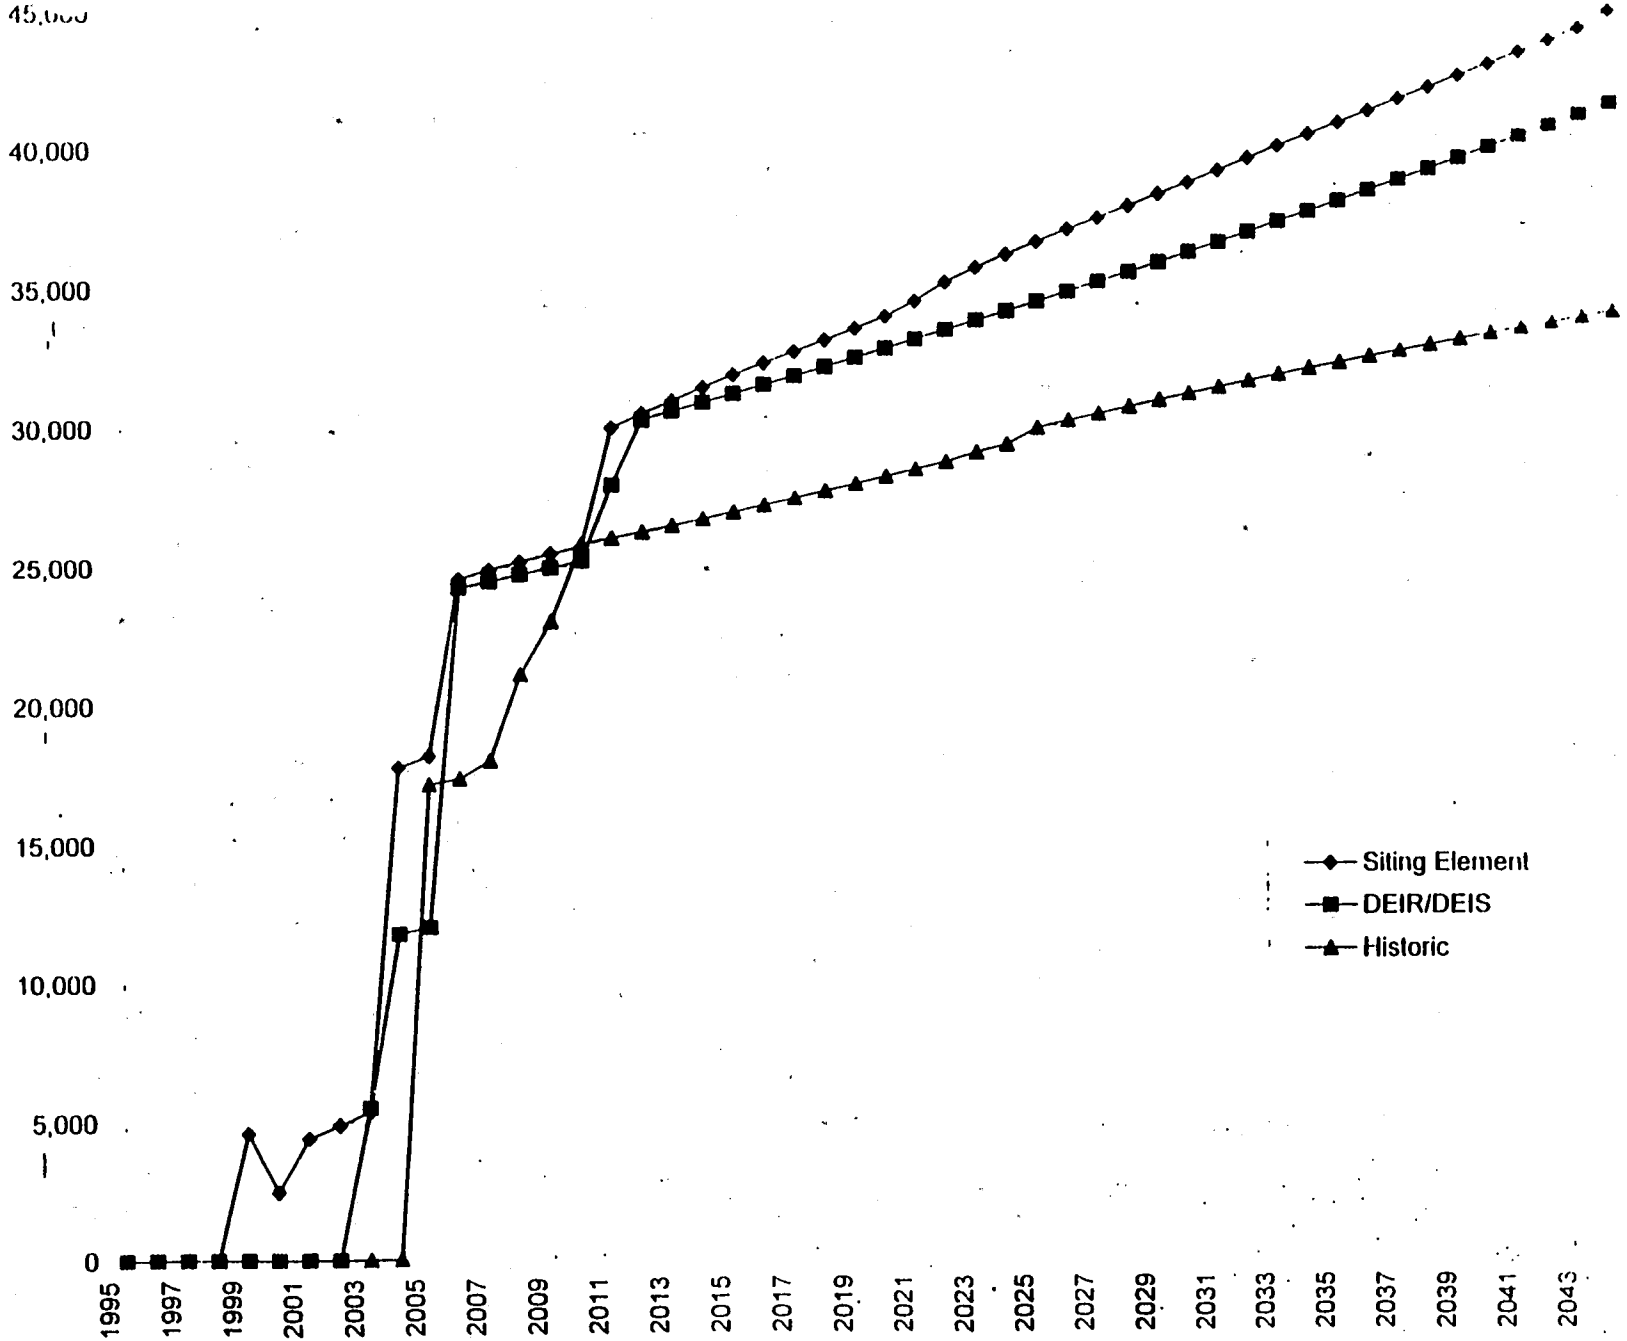

Figure IV-1. Comparison of Disposal Need Using Alternative Projections

year 2000. Moreover, the Hispanic share of the population (at 38 percent in 1990) is projected to rise to 46 percent by the year 2000. Hispanic population growth is fueled by larger family sizes and the continued influx of immigrants. White Non-hispanics are declining in share due to the outflows of population. For example:

- During the 1992-93 period, 112,800 persons moved out of Los Angeles County.
- Southern California Association of Governments has just recalibrated its projections for the five-county area downward by over half a million. They estimate that about 95,300 persons will leave the five-county SCAG region each year from 1995 to 1999. After the year 2000, the number of annual out-migrants from the SCAG region will rise to 135,000.
- The State Department of Finance estimates that almost all the growth Los Angeles County will experience over the next five years will result from immigration from abroad.

Los Angeles County has been transformed from a primarily white (Non-hispanic) population to one where Hispanic-, Asian-, and African-Americans account for 60 percent of the County's population.

3. Changing Income Structure

The vacuum created by the loss of a large number of high wage jobs associated with manufacturing and aerospace has been filled by service sector jobs paying lower wages with fewer benefits. About two-thirds of the County's Hispanic population are in non-manufacturing jobs. Hispanic-, Asian- and African-Americans are more likely to be located in the services sector, which is devoted to the generic consumption and maintenance activities required or expected in large urban areas. The kinds of retail and services provided -- markets, small to medium size retail stores, restaurants, car repair and medical care -- account for most of the low-wage job growth experienced by Los Angels County since the late 1980s.

Workers in lower occupation levels receive lower wages. With less discretionary income to spend, consumer patterns are less wasteful. Many anecdotal observations have been made

about the "conservation behaviors" of recent immigrants and lower income households who continually seek ways to extend the uses of material goods and products.

4. Implications of Waste Disposal Demand

The population forecast used in the DEIR/DEIS is too high. Any population projection estimated prior to 1990 will inflate future population growth. In 1993, the latest report available, the State Department of Finance lowered its population projections. In 1995, SCAG adjusted its 1990 population projects downward for the five-county region. The center for the Study of California's Economy has also lowered its population projections in its latest 1995 report.

The shift from a manufacturing to a service base economy will change waste disposal demand for Los Angels County. In general, service base economies are more likely to use recyclable materials, create less sludge, and produce refuse that can be converted to fuels. Many of these newer industries are more efficient and produce less waste.

The aggregate numbers hide significant compositional changes. The latest projections are lower but all assume some degree of growth. More importantly, the growth will be driven by immigration primarily from Mexico, Latin America and Asia. These changes in the components of growth and subsequent compositional changes challenge basic assumptions that waste disposal patterns of the past will be replicated in the near future.

Lower household incomes mean less waste per capita is generated. The association of higher incomes with greater consumption and waste has been well established. The current outlook of greater shares of lower income, non-white populations in Los Angeles County over the next decade projects to declining tonnage of waste disposal demand.

C. IMPORT/EXPORT OF WASTE

The Siting Element shows that 2,220 TPD of waste were imported into Los Angeles County from San Diego, Ventura, Orange and San Bernardino Counties. This totaled 692,640 tons of solid waste that were imported and disposed of in Los Angeles County landfills in 1995. The Siting Element also reports that 74,880 tons of solid waste were exported from the County in 1995. This results in a net import rate of 1,980 TPD on a six-day/week basis and 617,760 for the year. The DEIR/DEIS indicated that in 1993 the imports and exports were about equal and that the exports were approximately 485 TPD. Clearly, something has changed. The imports into the County in 1995 amounted to six percent of the waste landfilled. However, these data, in the opinion of this report, do not accurately reflect the true situation, as discussed below.

The past assumption that imports are approximately equal to exports is no longer a good assumption. The current situation is too dynamic. Several recent events exemplify the changes that affect waste import and export, including:

- The agreement between Orange County and WMI diverts the waste that was imported into Los Angeles County from San Diego County going to Riverside County instead. This agreement provides for 168,000 tons per year.
- The agreement between Orange County and Taormina Industries calls for 350 TPD in January 1996, increasing to 2,000 TPD by January 1997.
- The prospect of future importation from Ventura County has decreased due to a recent landfill expansion in Ventura.

The quantities that are included in the quarterly reporting required by CIWMB will not provide the data necessary to project future inter-county waste flows.

- The data is taken on a sampling basis for a period of one week every quarter. This is then projected over the other 11 weeks in the quarter. To be accurate, the data should be taken continually and summed for the quarterly report;

- Taking the origin data on a periodic sampling basis allows waste disposers to change their disposal location for the sampling period, thus distorting the data. This practice has been common in 1995 and it is well-known in the solid waste industry in the Los Angeles area; and
- The sampling does not reflect the fluid situation of landfills in and around Los Angeles. This is shown by the contract entered into by Orange County and others as discussed in Chapter V.

Poor information leads to poor policy and management decisions. It is recommended that the County and the 88 cities institute actual accounting of solid waste by weight and encourage the CIWMB to modify the reporting requirements for solid waste facilities so that the data reflects actual practice.

V. CURRENT AND FUTURE LANDFILL CAPACITY

The California Integrated Waste Management Act of 1989 requires Los Angeles County to continually have sufficient disposal capacity to accommodate the upcoming fifteen years of projected disposal need. The County of Los Angeles Department of Public Works has extended their planning period considerably further into the future, to 50 years as discussed in Chapter II. To demonstrate the need for the proposed Elsmere Canyon Landfill, it must be shown that the existing solid waste disposal facilities available to Los Angeles County are incapable of handling the waste generated over the 15-year period.

In the Elsmere Canyon DEIR/DEIS[11], the County predicted the "time-to-crisis" as shown in Table V-1. This is the point when there is no available landfill capacity in the County. According to the DEIR/DEIS, this occurs in 2004, when an Unsatisfied Need of 5,529 tons per day (TPD) capacity is projected.[12] The numbers and methodology used in Table V-1 and other DEIR/DEIS tables to project solid waste generation rates and disposal capacity were provided by the Los Angeles County Department of Public Works. This projection methodology covers the 50-year period preferred by the County.

Interestingly, in the Siting Element, the County provides a new and shorter "time to crisis". The County's projection from the Siting Element is shown in Table V-2 and indicates a Daily Disposal Capacity Shortfall in 1999. This loss of five years in the "time to crisis" is the result of the County's choice of data on which to base its waste generation projection as discussed in Chapter IV. In the Siting Element, the County has shortened the planning period to the 15 years required by AB 939. Summary data are presented in this Chapter, and year-by-year tables from which these summaries are prepared are included in Appendix F. The procedure used in Appendix F takes the same basic format utilized by the County "time-to-crisis

[11]Developed from Table 3.3.1, page 3-11, *Draft Environmental Impact Report/Draft Environmental Impact Statement*, Elsmere Canyon, USDA and LA County, January 1995. Format and data are the same.

[12]Actually, the table is abbreviated and does not show all of the data, including 2004. A year-by-year table is presented in Appendix F.

2004	59,302	50.00%	29,651	1,977	27,674	17,789
2005	60,212	50.00%	30,106	1,977	28,129	18,200
2006	61,052	50.00%	30,526	1,977	28,549	24,565
2007	61,822	50.00%	30,911	1,977	28,934	24,899
2008	62,524	50.00%	31,262	1,977	29,285	25,205
2009	63,158	50.00%	31,579	1,977	29,602	25,480
2010	63,725	50.00%	31,863	1,977	29,886	25,727

ASSUMPTIONS:

1. The waste Generation Rate was estimated using the CIWMB's adjustment methodology, utilizing population and economic projections available from the State Department of Finance and the Southern California Association of Governments.
2. 25% Diversion Rate in 1995 increases to 50% by 2000 and thereafter.
3. Sunshine Canyon Landfill becomes operational on July 1, 1996.

NOTES:

1. The 1995 diposal need quantity will be updated in the final CSE once complete 1995 Disposal Quantity Reporting Data are available.
2. "tpd-6": tons per day, 6 days per week.

Source: Los Angeles County Department of Public Works, January 1996.

tables, and modifies the calculations.

The presentations in the DEIR/DEIS and the Siting Element developed by the County [illegible] time to Crisis" or time to Daily Disposal Shortfall, due to its flawed assumptions and the selection of improbable scenarios. Specifically, the County fails to:

- project landfill operation at historically based waste acceptance rates (The landfills listed in Table IV-1 are all assumed to be operating at their maximum permitted capacity, so that in a given year, the projected amount of disposed waste can exceed the generated waste by up to 2.6 million tons, or over 7,000 TPD.);
- project the export of County-generated waste to out-of-County landfills;
- project the utilization of inert landfills, which have capacity for the inert fraction of the MSW stream;
- consider banning inappropriate materials, i.e., inerts and sewage sludge, from Class III landfills in Los Angeles County;
- include the capacity of the two waste-to-energy facilities operating in Los Angeles County; and
- consider the impact of the high diversion goal adopted by the City of Los Angeles.

The following section of the report adjusts the "time-to-crisis" calculations to account for the above factors. This is done in an incremental, step-by-step approach using a computer model that starts with the County's waste generation projection as published in the Siting Element and discussed in Chapter IV. The computer model starts with 1995 and projects waste generation for the next 50 years. Year-by-year tables are presented in Appendix F, which show the individual landfill and other waste allocations used to identify the exact "time-to-crisis" years and the individual effect of each step-by-step adjustment discussed in the text. Using the County's high waste projection emphasizes that alternatives to landfilling can and should be the primary thrust of the County's solid waste planning.

The majority of the information used in the adjusted tables is taken directly from documents and tables generated by the Los Angeles County Department of Public Works. The

County's calculations as shown in the Siting Element and presented in Table V-2, projects Los Angeles County to reach a "crisis" in disposal capacity in year 1999. However, as the landfill [illegible] assumptions in Table V-2 are modified in subsequent tables, it is revealed that the Los Angeles County solid waste disposal capacity is not in a "crisis." In fact, the "crisis" year is extended to 2014 -- fifteen years later and beyond the AB 939 planning period -- using the cumulative modifications discussed below.

A. WASTE MATERIALS FLOW MODEL

A computer model was developed to estimate the flows of solid waste materials generated in Los Angeles County. The model allocates the waste among waste-to-energy, diversion, and other alternatives to landfilling; and then allocates the remaining waste among the County landfills. Any unallocated waste is Daily Disposal Shortfall.

The computer model projects the quantity of waste needing disposal in the landfills in Los Angeles County beginning in 1996 and running through 2044. As mentioned above, the model uses the quantity of waste generated in each year projected by the County in the Siting Element. This is expressed as a daily rate based on a six-day week, as is the case in the solid waste permits. A portion of the waste generated is allocated to diversion, based upon the diversion rates projected by the County in the Siting Element. Waste is also allocated to the two waste-to-energy facilities at their capacity. Whatever waste remains each year is then variously allocated to landfills and diversion alternatives under a number of solid waste management strategy scenarios; each of the scenarios are designed to evaluate the differential impact of the various solid waste management strategies available to the County.

There a number of assumptions and parameters that are constant throughout all scenarios. These are:

1. Seventeen (17) permitted Class III landfills in Los Angeles County are included in the model. All are operating as of January 1996, except Sunshine Canyon -- which begins operating January 1997. No new landfills are opened.

2. The landfill daily allocations are initially based upon actual historic usage (1993), and rise to the permitted daily capacity as required. Total permitted capacity is the limiting factor as to how much a landfill can accept in the initial scenarios. These capacity quantities are taken from the Siting Element and are reproduced in Table V-3.

3. The waste to energy facilities are operated at 85.7 percent of maximum continuous rating (MCR). This percentage is the availability factor that allows for facility outages for preventive maintenance and repair. It is a conservative figure, as these plants can operate between 90 and 95 percent of MCR. The 1,760 TPD MCR is a seven-days-per-week figure, which is converted to the six-days-per-week figure used by the County. Therefore, 1,760 TPD on a seven day basis becomes 2,053 TPD on a six day basis. When multiplied by the availability factor of 85.7 percent, the result is 1,760 TPD on a six day basis. Also, no landfill space is allotted to the ash. This is because the Sanitation Districts are mixing the ash with cement to make concrete, then crushing the concrete, and using it for road sub-base. The County, in their calculations, uses 1,977 TPD permitted capacity for these facilities, which is higher than the plants' physical capacity.

4. The Lopez Canyon and BKK landfills are closed at the end of 1996.

5. The composition of the waste generated in Los Angeles County is that documented in the Interim Database assembled by the CIWMB and dated 1993.

The model allocates the quantity of waste generated each year based upon the historic actual uses of each landfill. For example, historically Puente Hills landfill has accepted about 16 percent of the County's annual quantity of waste needing disposal. Therefore, in projecting future disposal, the model attempts to maintain this proportion, even though Puente Hill's Permitted Daily Capacity is higher. As landfills reach their Total Permitted Capacity, or Expanded Capacity in Scenario 7, and close, the model allocates more waste to the open landfills -- until Permitted Daily Capacities are reached. Each landfill's Daily Permitted Capacity is never exceeded. Waste that cannot be allocated is summed as Unsatisfied Disposal Need. Los Angeles County overestimates the utilization of the landfills in the Siting Element. This is done by always projecting that landfills will be used at their Daily Permitted Capacity. This approach accelerates the "time to crisis" in the Siting Element by 2 years compared to that discussed in Section C, Landfill Waste Acceptance Rates.

Table V-3. Los Angeles County Landfill Capacities in Tons

Landfill	Remaining Permitted Capacity Jan. 1, 1996	Expanded Capacity	Permitted Daily Capacity	1994 Actual Utilization
Puente Hills	29,774,000	64,400,000	12,000	10,945
Spadra	2,147,000	2,147,000	3,700	2,156

Pebbly Beach Disposal	40,345	40,345	33	4
U.S. Navy	48,100	48,100	1	1
Whittier-Savage Canyon	2,663,000	2,663,000	350	217

Countywide Siting Element, Los Angeles County Department of Public Works, January 1996.

The initial run of the computer model or scenario provides a baseline allocation of waste and follows the County's strategy, which is: do the minimum diversion required by AB 939 and landfill the rest of the waste. Six other solid waste management strategies or scenarios are offered. Each of these is discussed in the following paragraphs. The rational for each strategy is discussed and the impact of that strategy is provided. The "time to crisis" is identified by the year that the County has an unsatisfied landfill need. The unsatisfied landfill need is also shown graphically to allow visual comparison of the impacts. Detailed values for each scenario are provided in Appendix F. Changes in the parameters in the Scenarios are not mutually exclusive and therefore have a cumulative impact, unless otherwise specified. This reflects the fact that an integrated solid waste management system for Los Angeles County is recommended to contain a combination of programs or strategies in order to achieve its objectives.

B. LANDFILL CLOSURES

In November, 1995 BKK and Browning Ferris Industries (BFI) announced that they had concluded an agreement which would close the BKK landfill in West Covina. The agreement has several contingencies including the reopening of the Sunshine Canyon landfill. Under the agreement BFI will acquire some of the assets of BKK including the ---transfer station and the Elsmere landfill project. The closure of the BKK landfill appears to be immanent and should occur before the end of 1996. Also, the City of Los Angeles has announced that it would close the Lopez Canyon landfill as of July 1996. This closure of these two landfills have an impact on the capacity available for Los Angles County waste.

The closure of the BKK and Lopez Canyon Landfills before they reach capacity reduces the County's available landfill space by some two to three million tons and reduces the useful life of the Los Angeles disposal system. To provide the most accurate representation of the current and future solid waste system for Los Angeles County, all subsequent landfill capacity and requirement estimates will be based on the assumed closure of the BKK and Lopez Canyon Landfills in 1996.

C. LANDFILL WASTE ACCEPTANCE RATES (SCENARIO 1)

In the Elsmere Canyon DEIR/DEIS and the Siting Element, the County projects Los Angeles County landfills to be perennially operating at their maximum permitted daily capacity. Table V-3 shows that in 1994 no operating Class III landfill (except perhaps the U.S. Navy) accepted the solid waste at its permitted capacity. On average, the County landfills operated at 53 per cent of permitted capacity in 1994. However, these landfills have historically operated at less than their permitted capacity.

The result of using maximum daily permitted capacities to calculate the "time-to-crisis" is that the annual total of disposed waste exceeds the projected total generated amount. For example, Table V-1 shows that 34,842 TPD of waste required landfill disposal in 1993; however, using the Daily Permitted Capacity, 43,224 TPD are assumed to be disposed.

Therefore, 8,382 TPD of waste, or 2.6 million tons per year, is shown to be disposed of in Los Angeles County landfills that is not generated. For all years before the "crisis" in Table V-1 and Table V-2, the projected total waste disposed of exceeds the generated amount.

It is unreasonable to project landfill acceptance rates that are independent of the key parameters, such as the waste generation and the diversion rates. Assuming that all landfills operate at full daily capacity leads to projected useful lives for each facility that are consistently short. Thus, the "time-to-crisis," based on the maximum utilization of landfills at the maximum permitted disposal capacities, does not present a true picture of landfill needs.

The model calculates data similar to Table V-2, except landfills are not assumed to operate at their maximum daily capacity, and the physical capacity of each landfill is assumed to be fully utilized. The total amount of waste requiring landfill disposal, Daily Disposal Capacity Shortfall, is proportionally divided among all of the operational landfills. The portion of the total generated waste allocated to each facility is prorated based on the tonnage of waste each landfill received in 1994, as reported by the California State Board of Equalization. For example, for Puente Hills in 1995, the average 1994 daily acceptance rate (10,945 tons) is divided by the summation of the average daily acceptance rates for all of the active landfills (47,912 tons) to yield 22.8 percent. This percentage is multiplied by the tonnage of waste requiring disposal to project the quantity disposed of in Puente Hills. The 1994 average daily acceptance rate for each landfill is shown in Table V-3. The daily acceptance rates were derived by dividing the annual tonnage received in 1994 (reported by the Board of Equalization) by 312 (days/year), to reflect six days of operation per week (6 days/week x 52 weeks). After the Chiquita Canyon landfill is expanded, the permitted daily capacity will rise-to 10,000 TPD. For the purpose of the model, an average daily acceptance rate of 7,000 tons was assumed.

The first year the remaining physical capacity of a landfill is less than the permitted annual capacity, the landfill is assumed to accept enough waste to reach capacity and begin closure. For example, when the remaining capacity of Lopez Canyon is less than 4,000 TPD (the permitted acceptance rate), it is assumed that during that year, Lopez Canyon will accept enough waste to reach its total permitted capacity.

As landfills reach their total permitted capacity and begin closure, the calculations used to allocate the total amount of generated waste to the remaining operational landfills are modified. When a facility reaches capacity, their daily acceptance rate is withdrawn from the summation of the daily acceptance rates used to prorate the allocation of waste to the various facilities, and the active landfills are responsible for a larger percentage of the annual generated waste. For example, when Lopez Canyon closes, the prorated percentage of waste allocated Puente Hills is 10,945 TPD divided by 45,561 TPD (the previous summation of the daily acceptance rates of 47,912 minus 2,351 tons, the daily acceptance rate of Lopez Canyon). However, this new percentage is not applied to the total amount of waste requiring disposal for that year because Lopez Canyon did accept some waste to reach closure. Therefore, the new percentage is applied to the total amount of waste requiring disposal minus the amount Lopez Canyon received to reach total capacity. The results of this calculation are shown in Figure V-1.

By comparing Table V-2 and Figure V-1, it is evident that projecting the landfills to operate at their maximum permitted capacity until closure has a negative effect on the "time-to-crisis. Table V-2 predicts that 1999 will be the first year Los Angeles County is without disposal capacity sufficient to accommodate the generated waste. However, Figure V-1, based on the rational assumption that the amount of waste landfilled will be approximately equivalent to the amount requiring disposal, projects 2001 to be the "crisis" year. Although there is potential for out-of-County waste to reach Los Angeles County disposal facilities, it can not be assumed that the landfills will continually operate at maximum capacity. Similarly, although there is potential for Los Angeles County waste to be hauled and disposed of outside of the County limits, it can not be assumed that the quantity of waste disposed of in Los Angeles County facilities will be less than the generated amount. From years 1995 to 2001, Table V-2 includes the disposal of over 12 million tons of waste in excess of the generated amount. This would mean that 24 percent of the waste shown to be disposed of in Los Angeles County Landfills over this period was not generated in Los Angeles County. For the year 1994, the Los Angeles County Department of Public Works reported that only 675 TPD, or 1.8 percent of the

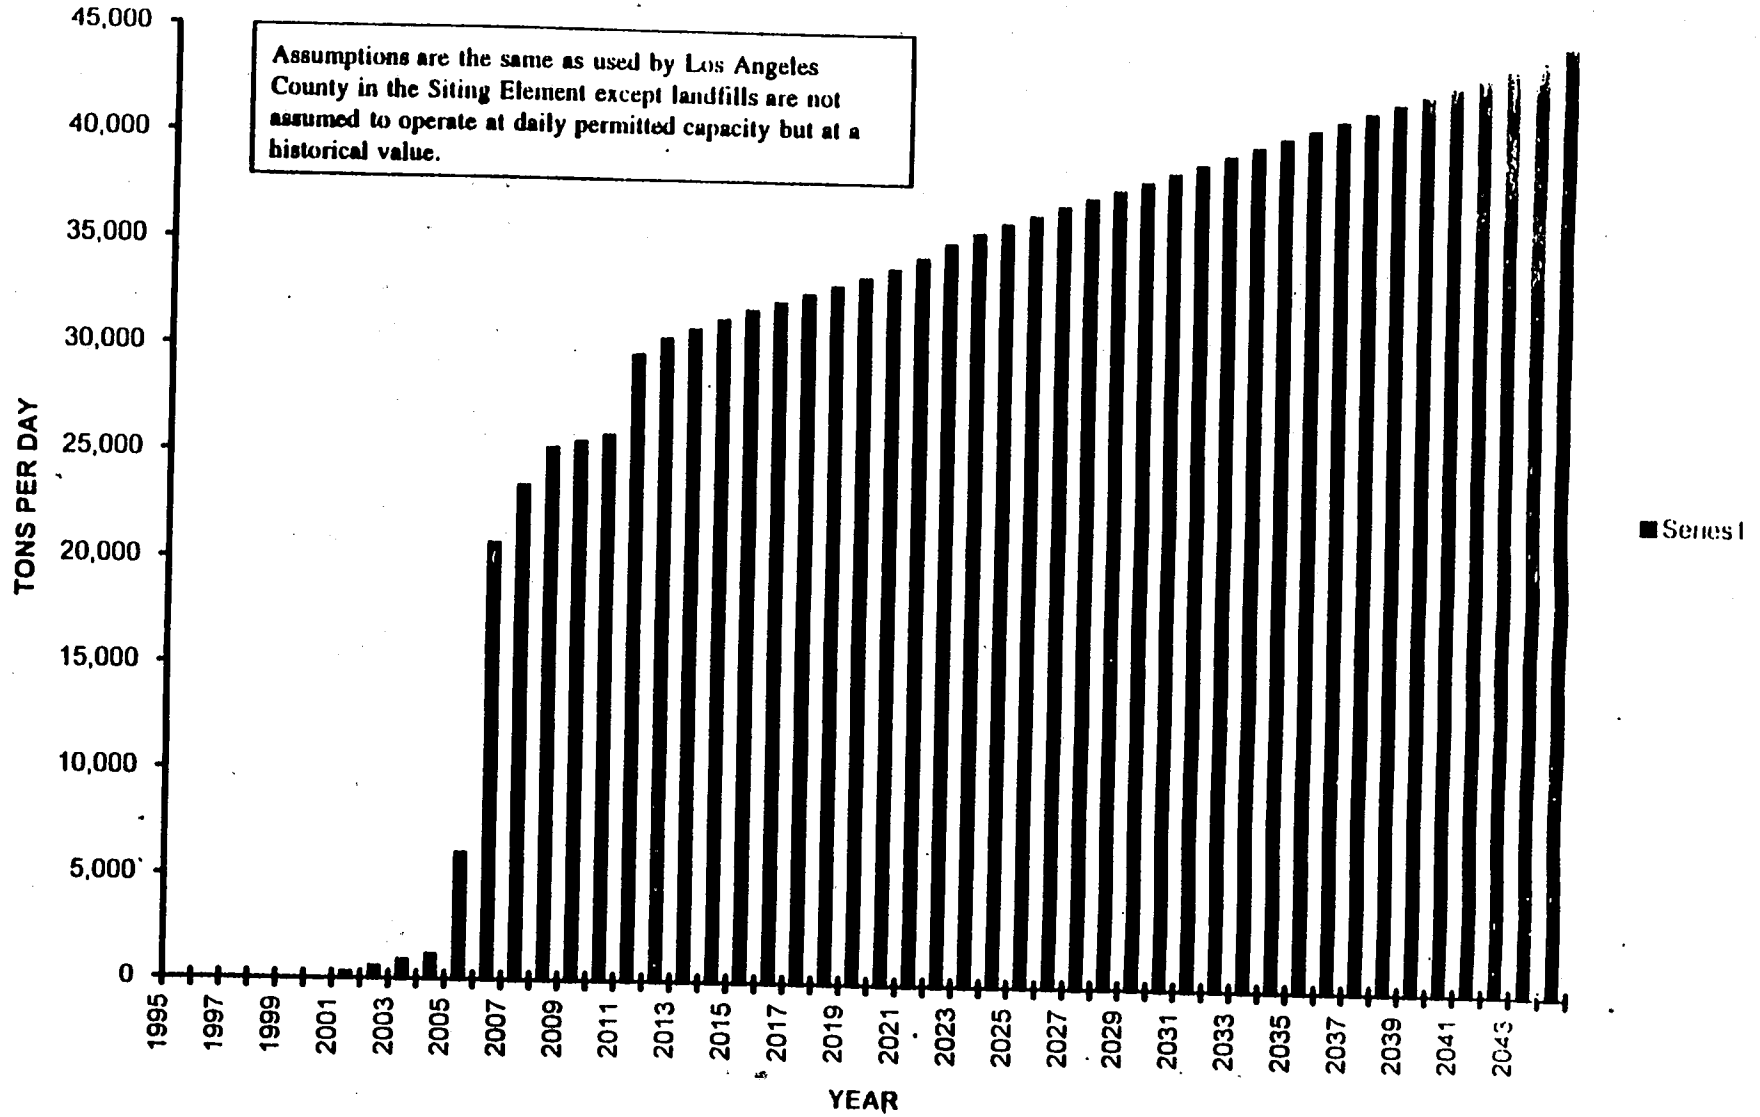

Figure V-1. Scenario 1 -- Using Historic Disposal Rates
Los Angeles County Disposal Need

disposed waste, is generated out-of-County.[13]

The first year that the County landfills experience a Daily Disposal Capacity Shortfall is 2001, when the Shortfall is projected to be 343 TPD. This is two years later than Shortfall is shown in the Siting Element. This difference is caused by the County approach of reducing the remaining capacity of each landfill by the Daily Permitted Capacity in its "time to crisis" calculation. The impact of this is mitigated slightly by the difference in the waste-to-energy facilities' capacity discussed above. The Shortfall in each year of the planning period is shown graphically in Figure V-1. As can be seen in the chart in Figure V-1, the Shortfall is small until 2006 -- when it is projected at 5,000 TPD. At the end of the AB 939 planning period, 2010, the Shortfall is 25,000 TPD.

D. OUT-OF-COUNTY ACCESSIBLE DISPOSAL FACILITIES (SCENARIO 2)

In addition to Class III landfills in Los Angeles County, landfill capacity accessible via rail or competitive truck transfer offers considerable potential in accommodating large amounts of County waste. Tables V-4 and V-5 list the out-of-County and out-of-State facilities that potentially could be utilized in a waste-by-rail system for Los Angeles County. These tables are adaptations of information developed by the City of Redlands[14] and the City of Los Angeles.[15]

Of the out-of-County facilities, Eagle Mountain, Rail Cycle/Bolo Station and Mesquite Regional Landfill projects all are planning for disposal capacities that exceed the proposed Elsmere Canyon Landfill. Western Waste, the operator of the El Sobrante Landfill, is proposing to expand the existing landfill and increase capacity from 4,000 to 10,000 TPD and a total capacity of 100 million tons. The final EIR for this is in preparation and it is expected that the

expansion permit will be granted to El Sobrante shortly. When that happens, sixty percent of the waste disposed of in El Sobrante must come from neighboring communities in Los Angeles, Orange, San Bernardino, and San Diego Counties. This expansion would allow for continued operations of the landfill from 1996 to 2026. Western Waste, the operator of El Sobrante, has submitted a proposal for 15 years of disposal services to the City of Los Angeles. Recently, Riverside County announced that it would be offering capacity at its El Sobrante landfill for $30.00 per ton. The Campo Solid Waste Management Project proposes a disposal rate of 3,000 TPD; rail haul would be required for this to be feasible.

Following its bankruptcy, Orange County began to explore the option of importing waste into the County landfills as a means of generating revenue. The Board of Supervisors approved this approach in November 1995 with the goal of importing 5,000 TPD by January 1, 1996. Contracts have been concluded with Waste Management and Taormina Industries for 2,000 TPD starting January 1, 1996. This waste is expected to be generated in Los Angeles County because Riverside, San Bernardino, and Imperial Counties all have landfills actively competing for waste.

As an example of the possible use of out-of-county facilities, effective November 1, 1995, San Bernardino County entered into a 15-year contract with Norcal Waste Systems, Inc. to provide a broad range of services relating to the administration, engineering and operation and maintenance of the County's network of landfills. San Bernardino County currently has 17 different landfills serving the 27 incorporated municipalities in the County in addition to the unincorporated area. The County receives approximately 1.3 million tons per year of solid waste for disposal.

As a result of various policy changes, the Los Angeles County landfills are in jeopardy of losing tonnage. As in other California counties, cities have the ability to contract with service providers for both collection and disposal services and sometimes do so for a combined service and do not designate where waste should be taken for disposal. Waste from several cities in Los Angeles County already have their waste disposed of outside of the county. It is possible that additional cities may follow suit.

If this situation were to occur and the County/Norcal had additional capacity that they could offer to other waste suppliers, e.g., cities in Los Angeles County or area haulers, San Bernardino County could be in a similar situation as Orange and Riverside Counties and market that capacity either directly or through their contractor. According to Gerry Newcombe, Deputy Director, San Bernardino County Solid Waste Management Department, the County's contract with Norcal allows for spot tonnage to be brought into the County system by either party.[10]

Of the out-of-State facilities, East Carbon, Roosevelt and Butterfield Station Landfills would accommodate daily disposal capacities that equal or exceed the proposed Elsmere Canyon Landfill. Franconia has a permitted capacity of 10 million tons and no daily disposal limits. The La Paz County Landfill has a capacity of 5 million tons. In addition, the CIWMB reports that both the Franconia and La Paz County landfills have the potential for expansion.

Waste from the County has been exported in the past and exportation has been expanded, beginning in January 1996. In the past, the County has assumed that the exports are approximately equal to imports. However, as mentioned above, Orange County has contracts with private waste haulers servicing Los Angeles County to provide disposal at their (i.e., Orange County) landfills for 4,000 TPD, beginning January 1, 1996. These contracts, and others that are planned, will result in significant net exports of waste from Los Angeles County. These exports, and others that could result from Orange County's decision to import waste, are not considered in the Siting Element.

Waste export depends on transfer stations to be efficient. Presently there are 19 transfer stations in Los Angeles County with a combined capacity of over 50 percent of the waste disposed in the County. These transfer stations depend on large trucks with a maximum payload of 22 tons. Table V-6 lists eleven transfer station facilities which are in the planning stages. These facilities all plan to provide access to rail transportation, some of these facilities are operating but not as solid waste rail transfer stations. Several of these are well along in the planning process and could be operational in 1997. The advantages of rail transportation are

[10]Personal conversation: G. Newcombe and H. Gershman, GBB, November 30, 1995.

lower operation costs, reduced truck traffic and lower environmental impact. A number of the projects include materials recovery processing in the planning of the rail transfer stations. One of these is the Puente Hills facility. The County Sanitation Districts have completed the final EIR[11] for a 4,200 TPD Materials Recovery Facility (MRF) located at Puente Hills with waste rail loading capability. The MRF is planned to divert 15 percent of the waste processed, resulting in 3,400 TPD requiring disposal. With rail facilities planned, it is logical that this waste would be rail hauled to one of the remote landfills discussed above.

While the Siting Element discusses rail haul, it does not take into account in computing disposal need. These exports have been, however, accounted for in this waste strategy. The exports, on a net basis, are at a rate of 2,000 TPD in 1996, and 3,500 TPD starting in 1997, which accounts for the Orange County contracts. Exports are raised to 6,000 TPD in 2001 to account for Puente Hills and other transfer station/MRF facilities on a conservative basis and continue through 2043.

The result is that the first year that Daily Disposal Shortfall occurs is 2007, extending the "time to crisis" by six years. The Shortfall in 2007 is 7,000 TPD and jumps to 16,000 TPD in 2008. This is shown on the chart in Figure V-2. At the end of the AB 939 planning period, 2010, the Shortfall is 20,000 TPD. This is 5,000 TPD less than Scenario 1, where export was not accounted for.

E. INERT MATERIALS AND BIOSOLIDS (SCENARIO 3)

Discussion of landfills in Los Angeles County usually focus on Class III sanitary landfills for non-hazardous materials. However, unclassified or inert landfills need to be included in solid waste management planning as well. Inert landfills can accept essentially non-decomposable materials, such as dirt and concrete. There are seven inert landfills in the County: Azusa, Calmat, Chandlers, NuWay, Peck Road, Reliance Pit #2, and Strathern, which were not

[11] *Puente Hills Waste Management Facility Environmental Impact Report*, County Sanitation Districts of Los Angeles County, May 1995.

considered in the Elsmere Canyon DEIR/DEIS and fully addressed for planning purposes in the Siting Element. These have a total permitted capacity of over 80 million tons.

In 1990, the Board of Equalization (BOE) shows 768,422 tons of inert materials delivered to County Class III landfills, which comprises 7.4 percent of the waste stream disposed of in these facilities.[12] Much of this material is recyclable, as discussed in Appendix B. However, assuming that it must be landfilled along with the current material accepted at these landfills, the permitted inert landfill capacity will accommodate the projected amount of inert material for the next 40 years with no additional recycling.

This waste management strategy assumes that inert material is prohibited from disposal in Class III landfills in the County. Also, it assumes that inert materials are banned from Class III landfills starting in 1996 and that these landfill bans will be enforced. However, even when bans are enforced, some amount of material slips by. Thus, for this Scenario, it is assumed that the effectiveness of the ban is 70 percent.

Additionally, approximately 500 TPD of biosolids (sewage sludge) are being landfilled currently by the Sanitation Districts. While this is not a lot of material and only totals some 156,000 tons per year, there are viable alternatives to this practice as discussed in Appendix B. In Chapter IX, it is recommended that biosolids be banned from disposal in County landfills. This material is totally under the control of the County and the Sanitation Districts and, therefore, the ban should be 100 percent effective. A landfill ban on biosolids does not impact the year in which Shortfall occurs, but it does make a positive impact.

These bans result in a net reduction of six percent in landfill disposal need. The implementation of this solid waste option extends the first year that Daily Disposal Shortfall occurs by two years, to 2009, as shown in Figure V-3. This Shortfall is 4,000 TPD in 2009, at the end of the AB 939 planning period, 2010, it increases to 13,000 TPD.

[12] CIWMB Interim Database Project - County of Los Angeles, August 4, 1993.

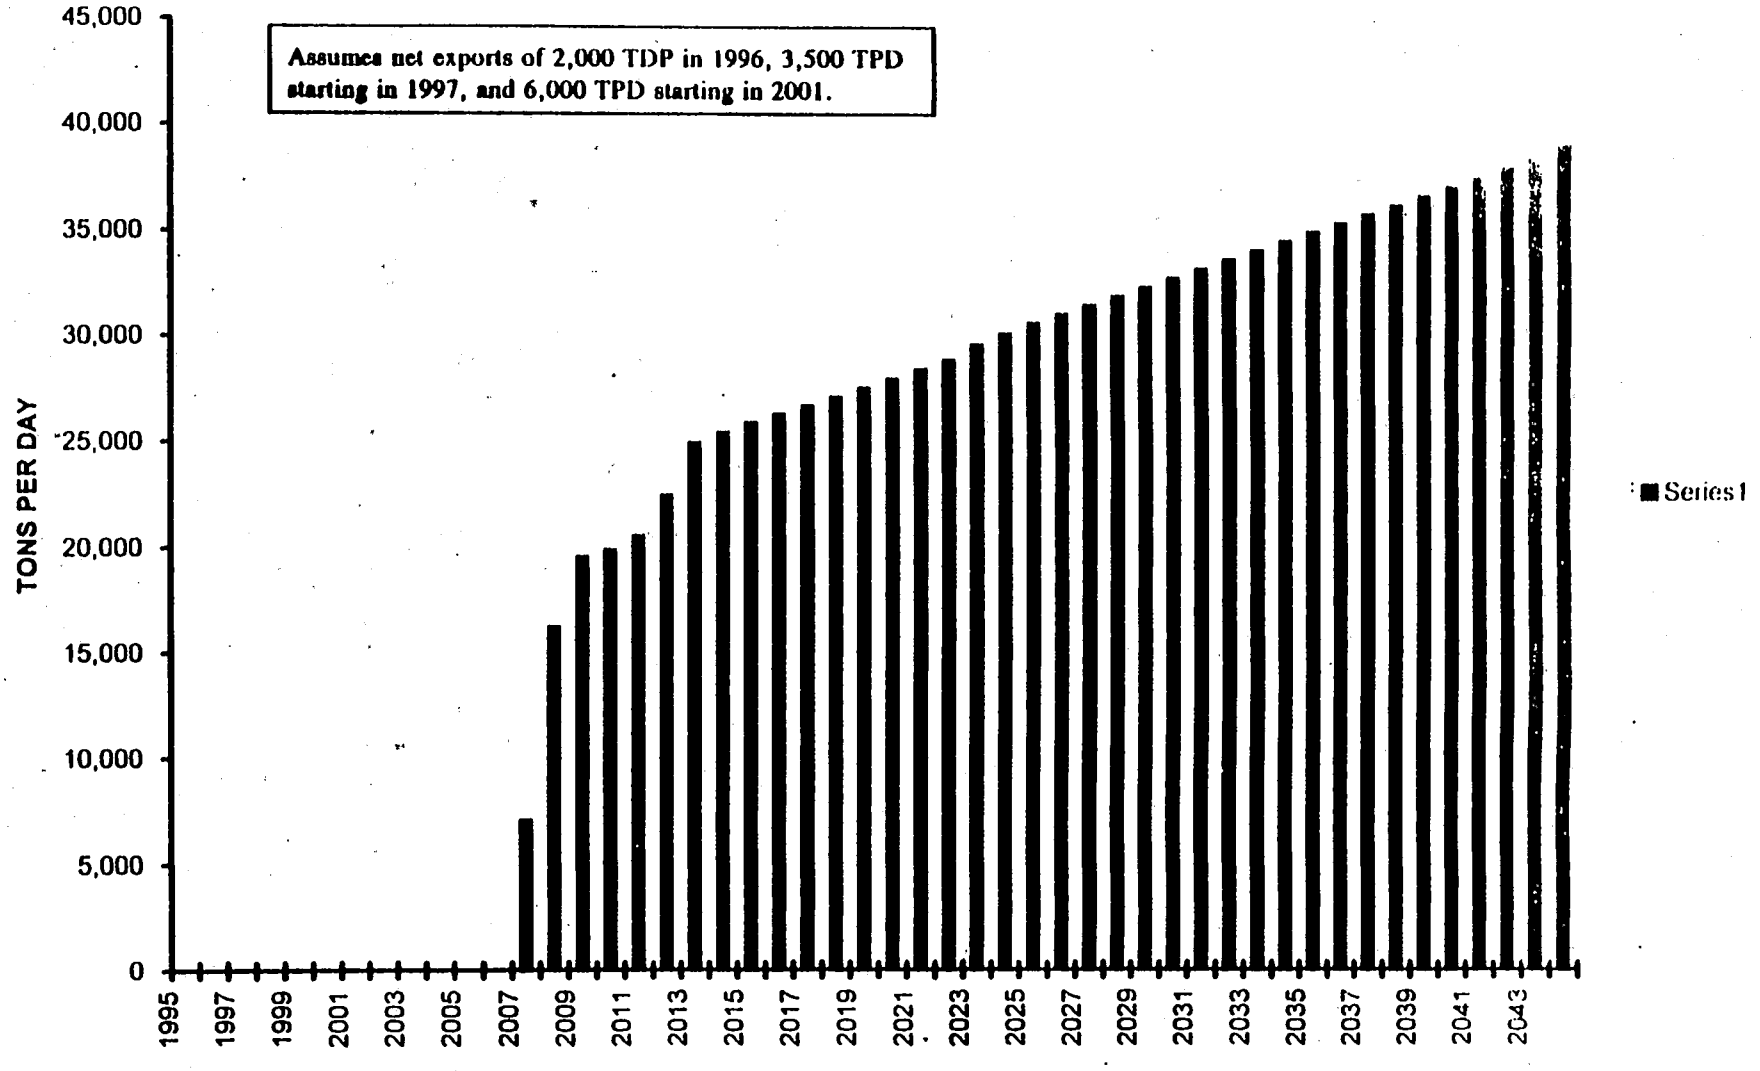

Figure V-2. Scenario 2 – Waste Export
Los Angeles County Disposal Need

F. CITY DIVERSION OF 70 PERCENT (SCENARIO 4)

The City of Los Angeles has adopted the goal of 70 percent diversion to be achieved in 2020. The planning in the Siting Element does not take the impact of achieving this goal into account in the calculation of landfill disposal need. In fact, the goal is not even acknowledged. The City generates 39 percent of the total waste generated in the County; diversion of 70 percent of this waste and diversion of 50 percent of the remaining waste generated in the County will result in an average of 59 percent diversion County-wide. Additionally, it is the position of this report that the County should be more proactive in the diversion of waste from landfills. One step the County could take is to adopt the 70 percent goal for the unincorporated areas to demonstrate the County's commitment to a diversion-based policy.

This strategy shows the results of the landfill disposal need calculation when the City and the County unincorporated area meet the 70 percent diversion goal. The waste for which the County is responsible has been included because the County has control of solid waste management policy and implementation of those policies. In Chapter 9, which outlines the recommendations for County policy, it recommended that the County adopt the 70 percent goal. Scenario 4 assumes that the City of Los Angeles and the County unincorporated areas achieve 70 percent diversion in 2020. The unincorporated area generates approximately nine percent of the total waste in the County. This added to the City's 39 percent results in 47 percent of the waste generated in the County subject to the 70 percent goal. The result is a total of 59 percent diversion in 2020.

This option does not have any impact until after the year 2000. Starting in 2001, the impact is to increase the diversion of the entire County by half a percent per year until 2020. The result is to extend the first occurrence of Daily Disposal Shortfall by one year compared to Scenario 3, to 2010. This can be seen in Figure V-4. The amount of the Shortfall is 5,700 TPD in 2010, compared to 11,700 TPD in 2011. Further reductions occur in subsequent years, as can be seen by comparing Figure V-3 and V-4.

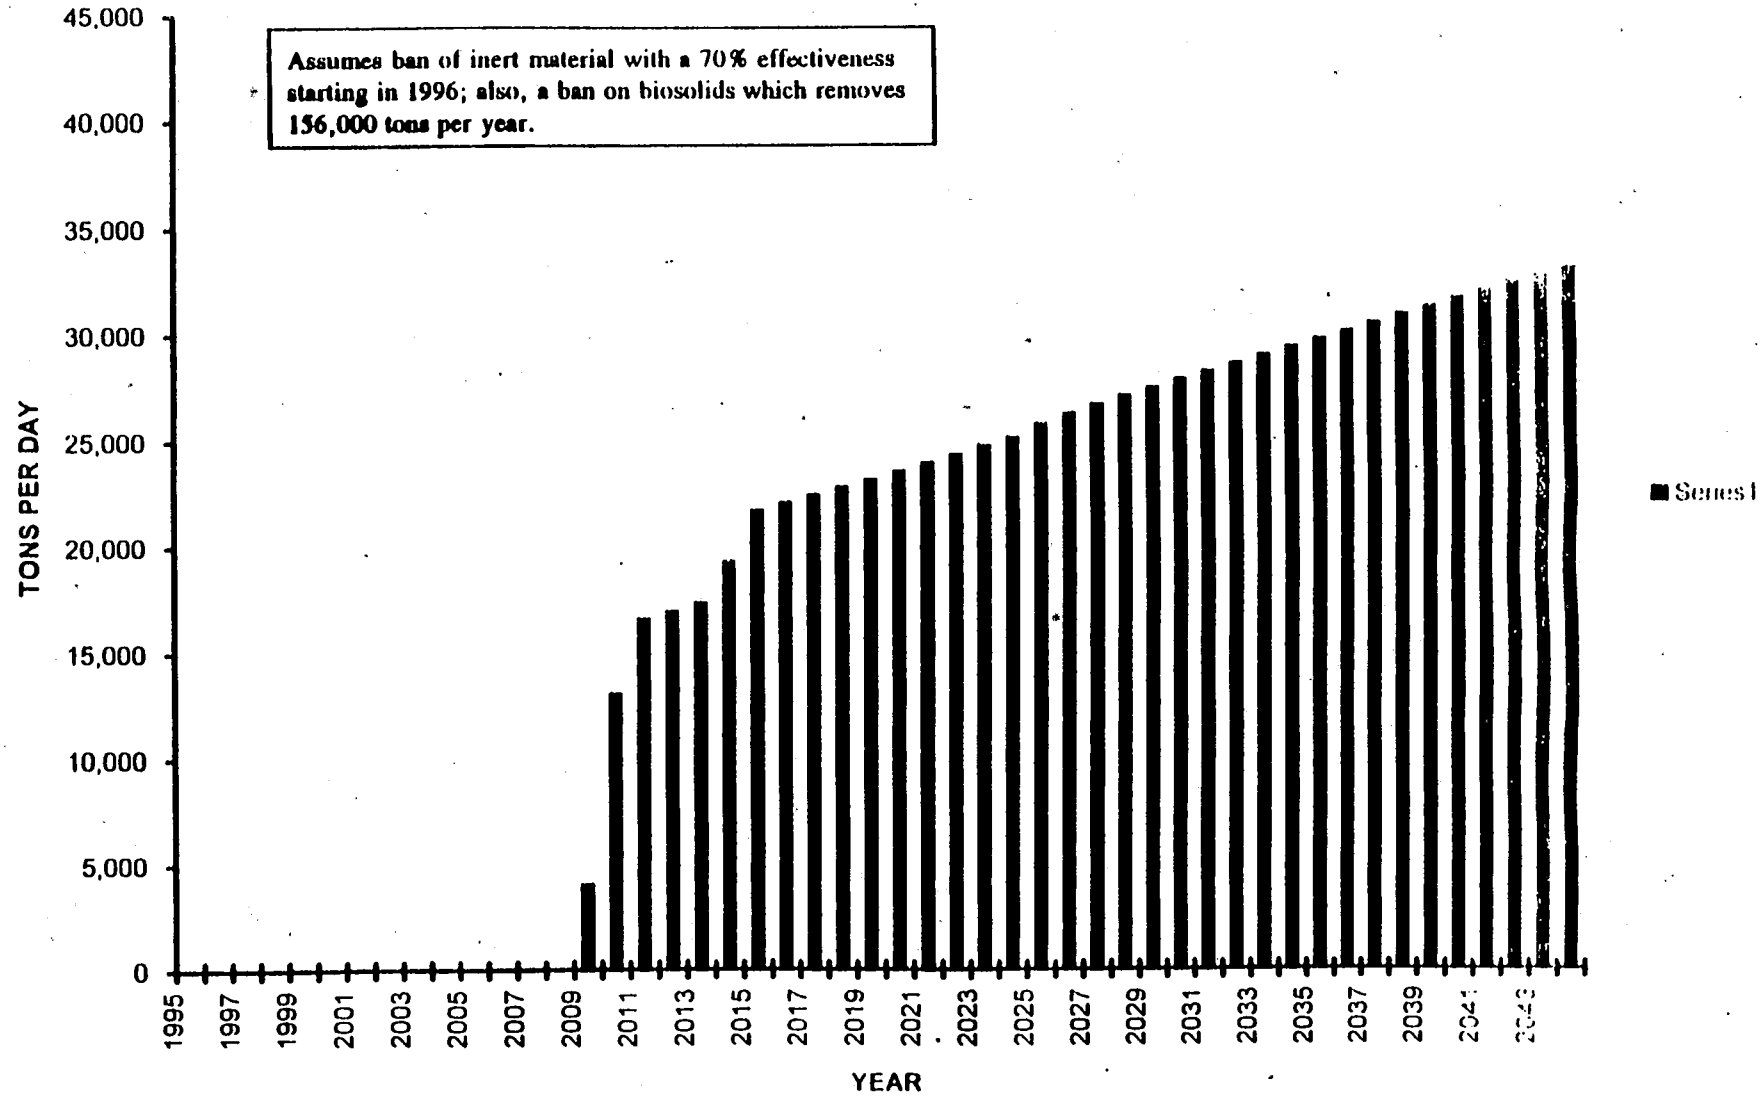

Figure V-3. Scenario 3 -- Inert Material and Sewage Sludge Bans Los Angeles County Disposal Need

The combination of the first four solid waste management strategies:

- Projecting landfill use based upon waste available and historic usage rather than permitted daily capacity;
- Export addition;
- Insert material and sewage sludge bans; and
- Diversion goal of 70 percent for the City and the unincorporated area.

result in essentially postponing the occurrence of Daily Disposal Shortfall beyond the AB 939 fifteen year planning period.

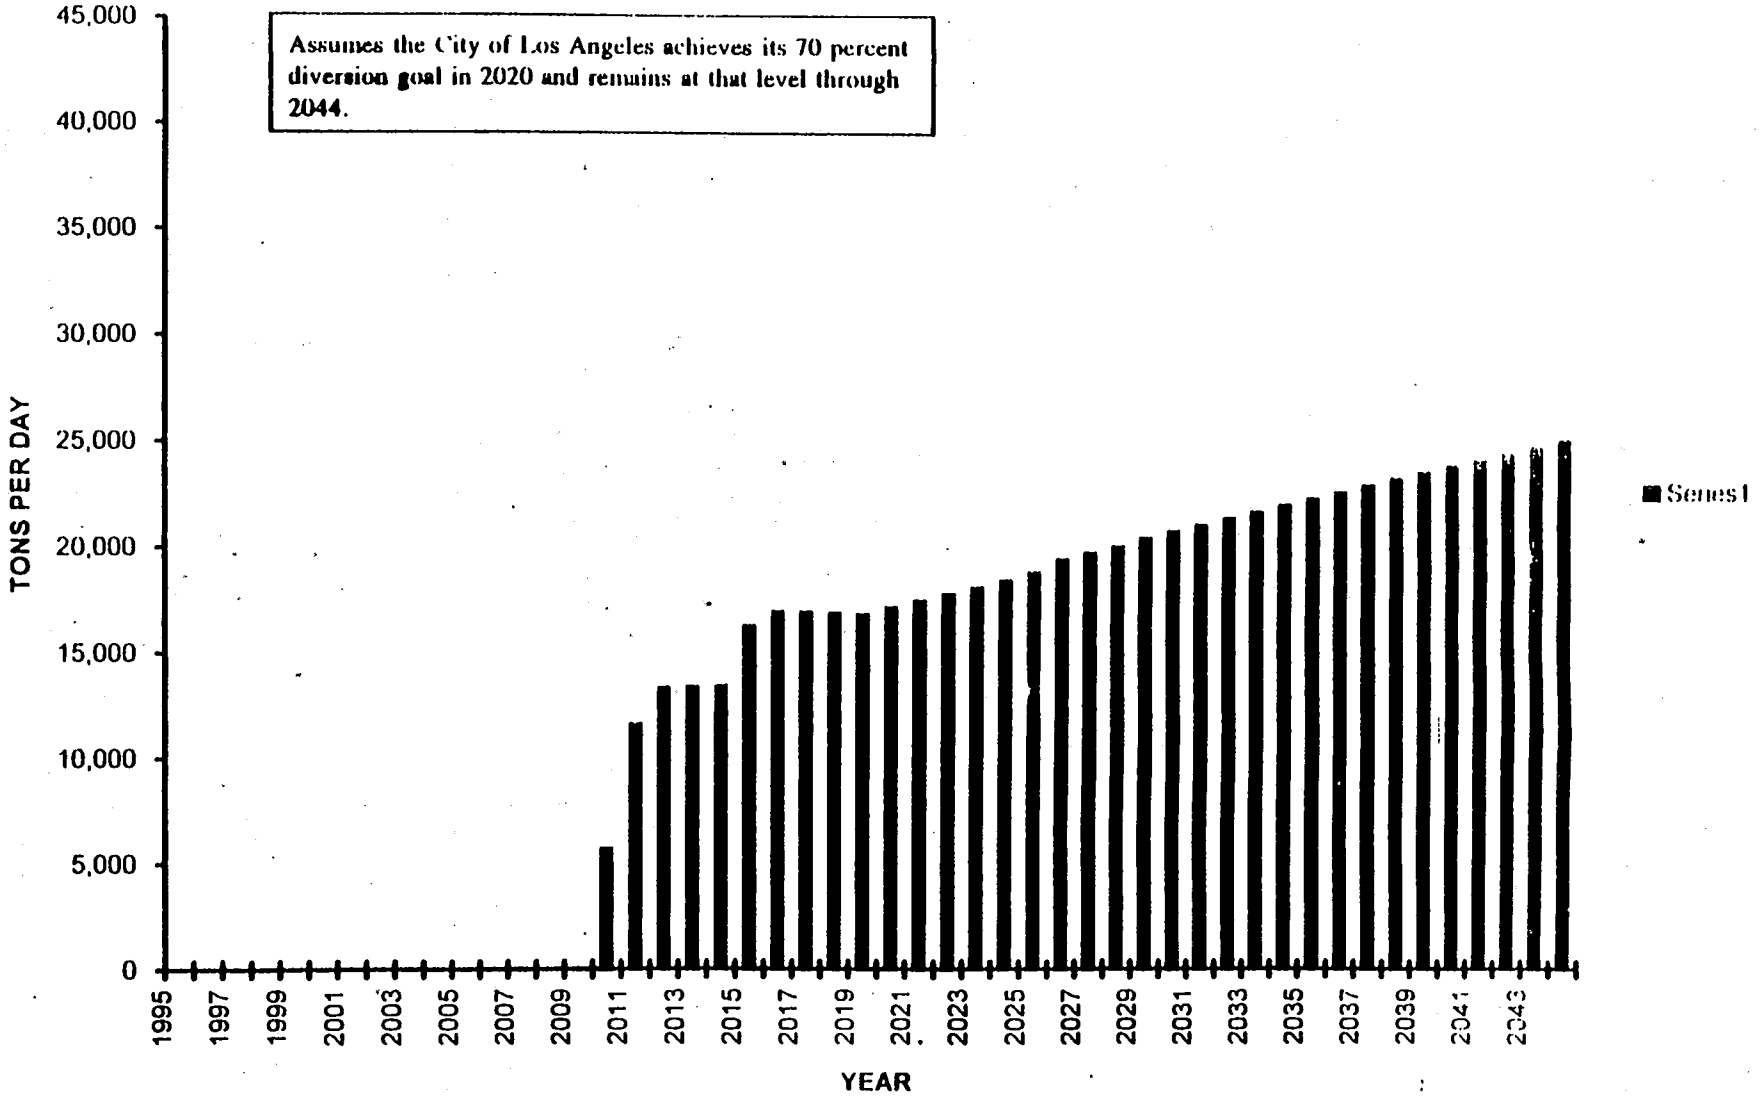

Figure V-4. Scenario 4 -- Diversion Goal of 70 Percent Los Angeles County Disposal Need

VI. STRATEGIES FOR CONSERVING LANDFILL CAPACITY

Considerable experience has been gained in recent years by public and private landfill operators in utilization of technologies and management techniques for conserving landfill space. A detailed discussion of landfill conservation approaches, and examples of their applications, are provided in Appendix C. For the purposes of estimating the amount of current landfill capacity in Los Angeles County that could be saved for future use by the application of landfill conservation techniques, two have been selected: (1) chemical or foam cover and (2) biostabilization. The application of these two techniques as applied to the landfills in Los Angeles County is discussed below.

A. CHEMICAL OR FOAM COVER (SCENARIO 5)

Chemical or foam compounds have been specifically developed to be used as intermediate daily cover on landfills and are available from nationally-reputable manufacturers. Their use is widespread and performance documented at numerous operating landfills. This experience shows that foam conserves between 20 and 33 percent of landfill capacity when used in place of daily cover soil, by allowing the replacement of the dirt by solid waste.

To project a "time-to-crisis" estimate for Los Angeles County based on the use of foam cover beginning in 1997, the total remaining capacity for each landfill was multiplied by 1.22 in the year it is converted to foam. The space saved by not using dirt accounts for the 22 percent capacity increase provided by foam cover.

Figure VI-1 is the County's "time-to-crisis" table, as modified in Chapters IV and V of this document, and showing phased-in use of synthetic foam cover at County landfills. The use of foam cover begins in 1997 with all landfills in the County using foam cover in place of dirt or other materials that consume landfill capacity.

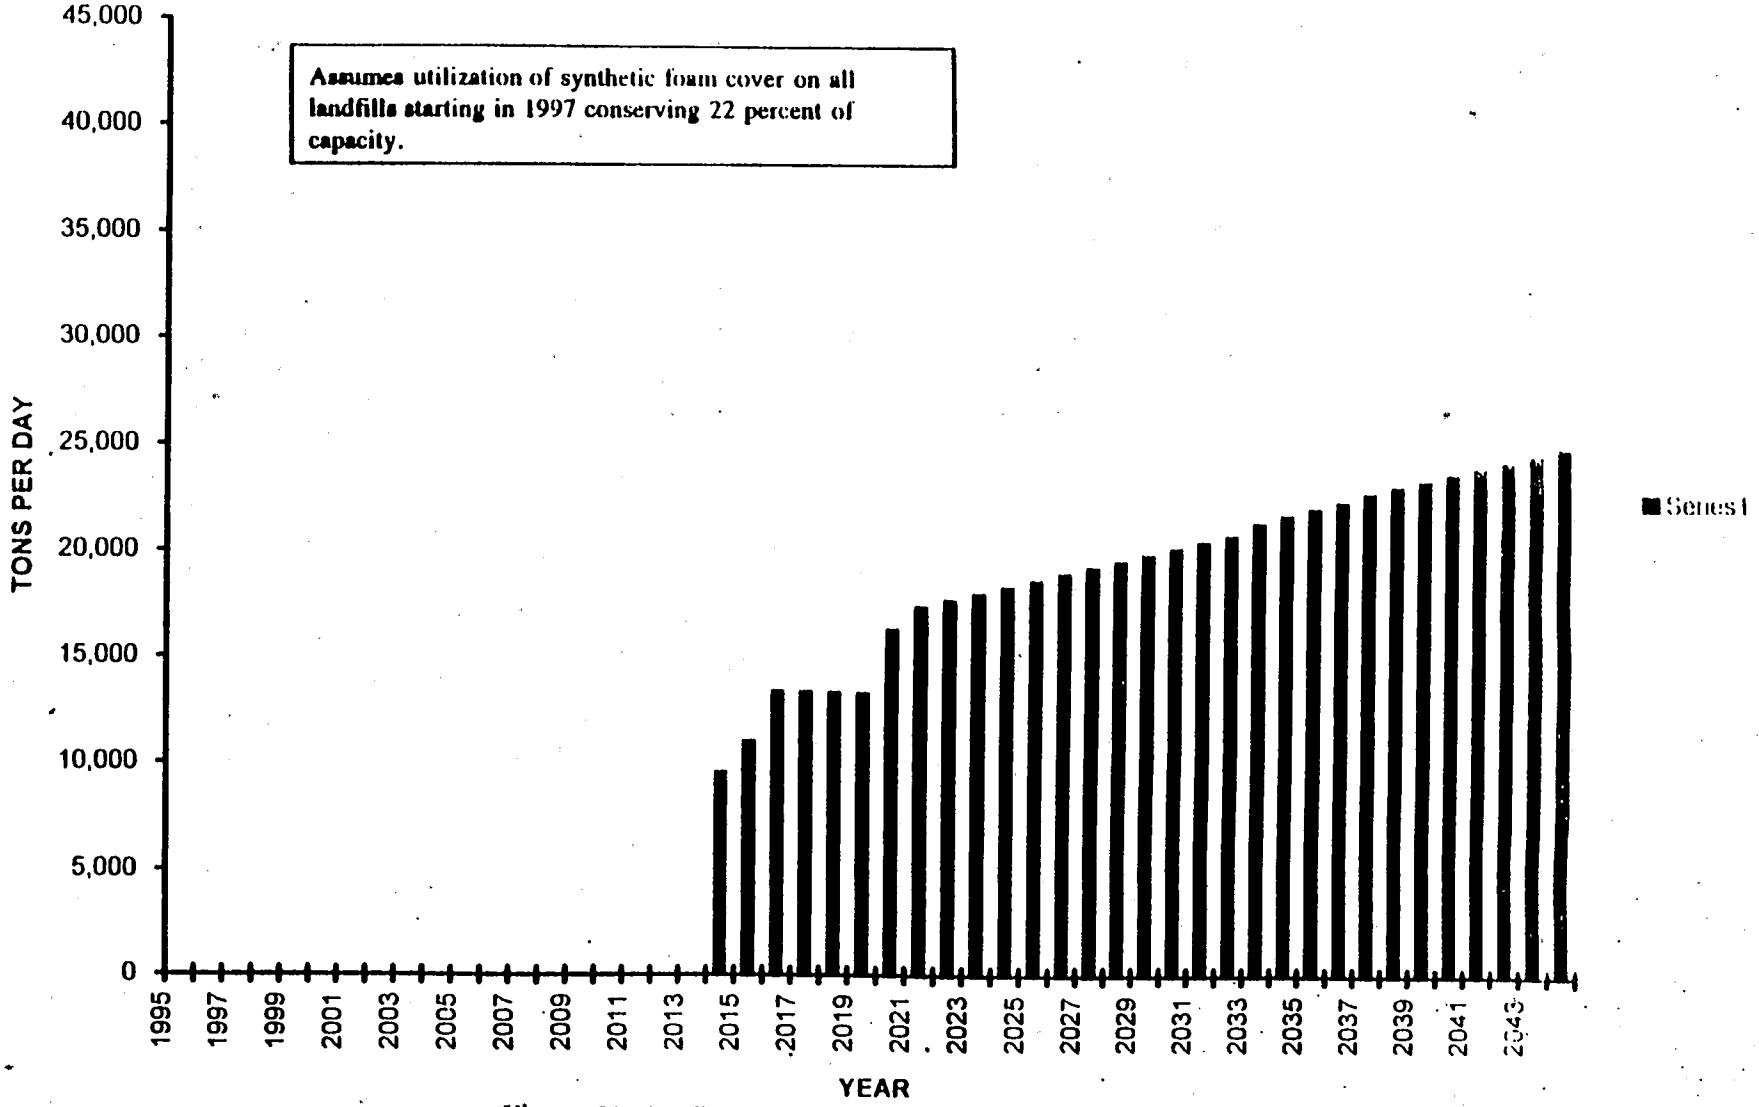

Figure VI-1. Scenario 5 -- Chemical Foam Landfill Cover Los Angeles County Disposal Need

The implementation of this technology extends the time until Daily Disposal Shortfall by four years, to 2014. In addition to moving the occurrence of Shortfall to 2014, foam cover significantly decreases the amount of the Shortfall in all subsequent years of the 50 year planning period. This can be seen on the chart in Figure VI-1.

B. BIOSTABILIZATION (SCENARIO 5A)

Current landfill management is based on a "high and dry" approach. Under this technique, both rain water and ground water are kept out of the landfill. Any water that does penetrate is collected and removed as "leachate. Leachate is treated in a waste water treatment plant and discharged. Opening and sorting old landfills has shown that very little breakdown of the organic materials takes place.[19] In many cases, old newspapers are still readable after 25 years.

Biostabilization incorporating shredding and leachate recirculation is a developing technology with excellent promise. This promotes the breakdown of the organic materials in the landfills, increases gas generation, and results in volume reduction. This allows additional waste to be deposited. Operating experience in Albany, New York indicates increases in landfill space utilization between 50 and 100 percent. At the higher levels, this could be thought of as "recycling" landfills. As mentioned previously, a discussion of operating techniques that allow additional waste to be disposed per unit of landfill volume are discussed in Appendix B.

Figure VI-2 shows the results achieved by application of this technology in the County landfills at the 50 percent level in conjunction with foam cover. Because the technology is developing and will take some time to implement, implementation is shown starting in 2000.

Figure VI-2 was developed using the same methodology as discussed in Section A except for each landfill, the amount of capacity consumed between years 2000 and 2043 is multiplied by 50 percent to estimate the capacity conserved due to biostabilization. This value is then

[19]Rathje, William. "Rubbish." *The Atlantic Monthly*, December 1989, pp. 99-109.

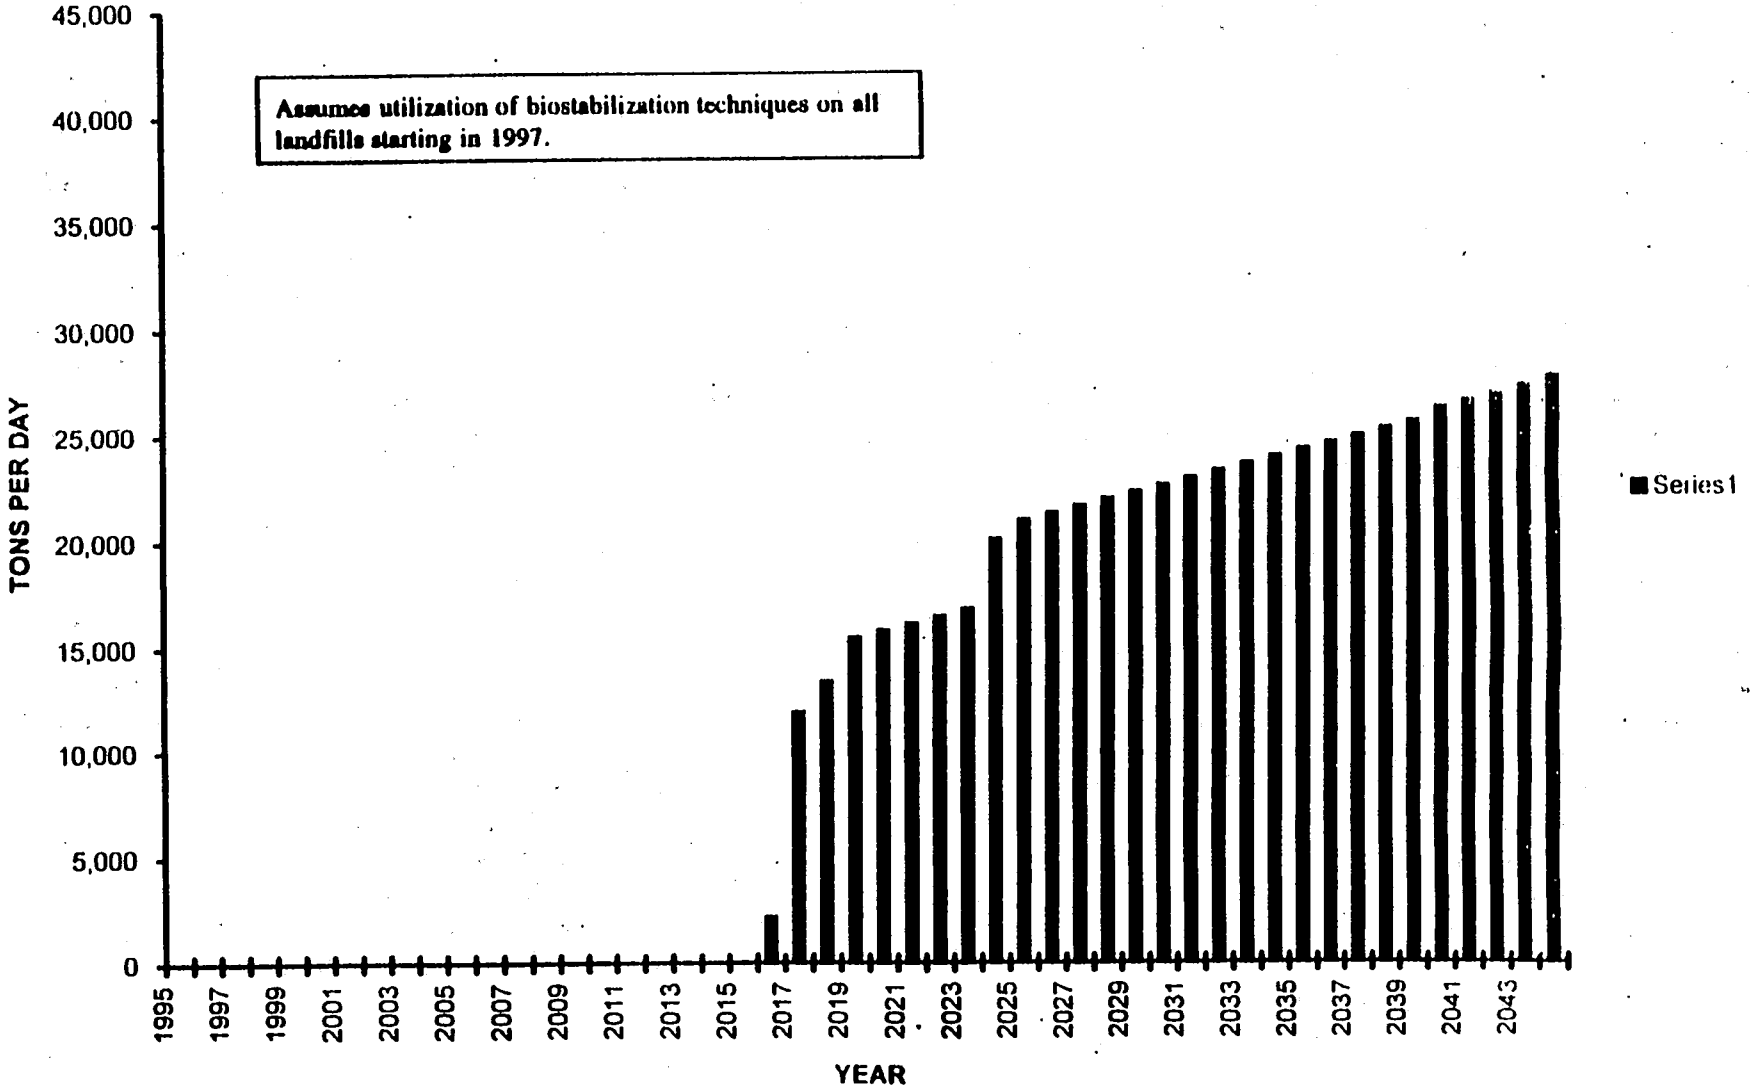

Figure VI-2. Projected Disposal Needs Through The Use of Biostabilization 1995

VII. DIVERSION OPPORTUNITIES

This Chapter focuses on the opportunities to increase diversion of solid waste from landfill disposal in Los Angeles County. The discussion provided below is a summary and evaluation of a more detailed analysis provided in Appendix B. Diversion Alternatives, supplemented by Appendix G. International Technology Applications. Appendix B looks at each of the available diversion alternatives presently in use by other communities in the U.S., assesses their appropriateness for implementation in Los Angeles County, and, where applicable, estimates the percentage of the County waste stream that could be addressed by each diversion alternative. The provision of information on alternative approaches applied in other countries in Appendix D further demonstrates that recovery of materials from the waste stream and avoidance of land disposal are not pioneering approaches to waste management, and are not unique to the U.S.

There is a correlation between a public policy that is committed to diversion and recycling and the achievement of diversion. The public policy is manifest in public documentation: statutes, regulations, planning reports and public information pieces (brochures, newsletters, press releases, instructional booklets, etc.). One familiar feature of a policy commitment to diversion is the diversion goal. Forty-one states have recycling goals and thirteen have goals of 50 percent or higher, including the state of California. The commitment is stronger and more effective when the goals are mandatory.

Many of the successful programs in the larger cities and counties have adopted and are actively working toward goals higher than state goals and on an accelerated schedule. These programs include: Seattle, WA with a goal of 60 percent and 1995 diversion of 53 percent for residential waste; King County, WA with a goal of 65 percent and a 1995 diversion of 49 percent; Ocean County, NJ with a goal of 60 percent and county-wide 1995 diversion of 59 percent where 11 of the 33 municipalities reported 50 percent or higher; and Minneapolis, MN that achieved the state goal of 50 percent in 1995.

The City of Los Angeles has adopted the goal of 70 percent recycling by the year 2020. San Jose achieved 43 percent diversion in 1995. This achievement shows what can be accomplished in only five years with a public policy decision followed up with a plan and implementation. However, in the "time to crisis" calculation the County has not accounted for the impact of the City's high diversion goal and its impact on the disposal needs.

The purpose of the exercise undertaken in Appendix B was not to identify a few selected technologies that could be calculated to bring Los Angeles County into compliance with the 50 percent diversion requirement by the year 2000. Instead, each technology or market was evaluated independently for its potential to address a specific portion of the County's waste stream. This allows comparison of what percentage could be diverted by each approach, assuming a reasonable capture rate for the type of material(s) addressed. The analysis was conducted by type of material, so as to avoid "double-counting." Diversion calculations for the materials were added to the computer model developed to calculate the landfill requirement as discussed earlier. The details of how these calculations are applied to the County Waste Stream are discussed in Appendix H.

This analysis shows that no single technical approach will meet diversion goals. However, by applying the full range of available technologies, summing together the fractions of the waste stream that could be diverted by each of the technologies deemed appropriate to Los Angeles County, the analysis shows that 74.5 percent of the waste stream could be diverted by recycling/reuse technologies by the year 2020. This is well beyond the legislatively-mandated 50 percent.

Also evaluated in this Chapter is the diversion potential of transformation (waste-to-energy) facilities. Transformation can be counted as 10 percent of the 50 percent diversion goal (i.e., a minimum of 40 percent must be diverted from disposal by other means) under California law. Review of the two existing waste-to-energy facilities and the potential of new facilities to reduce landfill capacity needs in Los Angeles County is discussed under Section VII.C below.

A. DIVERSION PROGRAMS

An analysis of current recycling programs and a diversion model to project future recycling rates was developed for this Chapter. Current program information is based on County-provided data, and diversion rates for individual materials, facilities, and programs are based on the discussion provided in Appendix B. In the discussion below, the year 1995 represents Level 1, Current Programs; year 2000 represents Level 2: Intensified Current Approaches; and year 2020 represents Level 3: Maximum Diversion.

1. Level 1: Current Programs

The current status of diversion programs can be summarized by saying that the County and the Cities have done the easy part. While not universal, residential diversion systems in the County include curbside collection, yard waste collection, and medium-level public information efforts directed to residents. Commercial and waste generators have developed, for the most part, only voluntary and economically-driven diversion programs. The County and most of the Cities have some public information programs directed toward the commercial and industrial sectors; however, these are not comprehensive efforts to maximize diversion. In summary, current programs are:

Residential
- Curbside Recycling Collection
- Yard Waste Collection
- Medium-level Public Information Campaign

Commercial/Industrial
- Voluntary Programs
- Economically-driven Programs
- Some Public Information Programs

In the DEIR/DEIS and the Siting Element, The County assumes that these programs will achieve 25 percent diversion in 1995. However, the Los Angeles County diversion analysis model, developed for this document and discussed in Appendix H, indicates a 20.33 percent

diversion rate in 1995. This rate reflects continued implementation of the above-mentioned programs. The fact that these programs have not been fully implemented, with uniform policy and administrative backup by the County and all 88 cities, is reflected in the recovery rates for the materials targeted in the programs. Recovery rates for individual recyclable materials are provided in Appendix H.

Table VII-1 shows the estimated overall diversion rate and the residential, commercial and industrial sector components from which this rate is derived on the first line of the Table (1995). Table VII-1 also shows that simply maintaining current programs will not achieve the 50 percent diversion goal required by AB 939 by 2000.

In order to attain 50 percent diversion in 2000, a new approach is required. As discussed in this document, the new approach is a County-wide policy shift to a diversion-oriented solid waste management strategy. Recommendations to the County for implementing this policy shift are presented in Chapter IX. These recommendations result in diversion programs that are executed by the public and private sectors in the County as well as by the County and the 88 cities.

2. Level 2: Intensify Current Approaches

The first step toward increasing diversion is to intensify the present approach to residential waste diversion, and increasing efforts in the commercial/industrial sectors. The commercial/industrial waste stream represents nearly half of the County waste stream. Increasing efforts in this area are essential to achieving the diversion goal. Level 2 efforts would include:

Residential
- Intensive Curbside Recycling Collection
- Yard Waste Collection
- Comprehensive Recycling Drop-off Facilities
- High-level Public Information Campaign covering source reduction, reuse, and recycling
- Mandatory Recycling Programs

Table VII-1. Projected Diversion By Sector for Intensive Programs

(TPD – 6)

Year	Total Waste Generation Rate	Residential Waste Generation Rate	Commercial Waste Generation Rate	Industrial Waste Generation Rate	Residential Waste Recovery Rate	Residential Percent Recovery Rate	Commercial Waste Recovery Rate	Commercial Percent Recovery Rate	Industrial Waste Recovery Rate	Industrial Percent Recovery Rate	Total Waste Recovery Rate	Total Percent Recovery Rate
1995	49,677	21,461	22,355	5,812	5,138	23.94	3,575	15.99	1,385	23.83	10,097	20.33

Commercial/Industrial
Mandatory Recycling Programs
Food Waste Composting Facilities
Comprehensive Recycling Drop-off Facilities
Public Information, Training and Assistance

In the residential waste generation sector, three new programs are recommended to meet the goal: (1) expanded curbside recyclables collection, (2) a system of comprehensive drop-off recycling centers, and (3) a more comprehensive public information program covering source reduction, reuse, and recycling. These programs are discussed in Appendix B. For the commercial and industrial waste generation sectors, four new programs are recommended: (1) mandatory recycling and diversion, (2) food waste composting, (3) a system of comprehensive recycling drop-off centers, and (4) a public information, training and assistance program targeted to these generators. This latter program should include waste audits, waste reduction, utilization of waste materials as industrial feedstocks, and recycling. The separate handling of food waste in the composting program will substantially lower the contamination of corrugated and other paper in the commercial waste stream.

The projected results of the policy shift and implementation of the Level 2 recommended programs is shown as the year 2000 line on Table VII-1. This Table indicates that implementation starts in 1996, expands through 1999, and is completed in the year 2000. The diversion analysis model projects an overall diversion rate of 48.57 percent for this scenario in 2000. While this projected rate essentially achieves the AB 939 goal of 50 percent diversion, it does not represent the full potential of a diversion-oriented solid waste management policy.

3. Level 3: Maximum Diversion

Full implementation of the diversion-oriented waste management policy requires additional programs to be developed and executed by the County and the 88 cities. Level 3 efforts include:

Residential
Intensive Curbside Recycling Collection

Yard Waste Collection
Comprehensive Recyclables Drop-off Facilities
High-level Public Information Campaign
HHW Curbside Collection
Mixed Waste Composting
Weight or Volume-Based Fees

Commercial/Industrial
Mandatory Recycling Programs
Food Waste Composting
Comprehensive Recyclables Drop-off Facilities
High-level Public Information, Training, Assistance and Enforcement
Commercial/Industrial Materials Recovery Facilities (MRFs)
Special Waste Management

Under the maximum implementation approach, three additional programs are recommended for the residential sector: (1) curbside collection of household hazardous waste (HHW), (2) mixed waste composting, and (3) variable rates. The first two programs are linked. A key problem encountered in implementing mixed waste composting facilities in the U.S. has been the quality of the end product as discussed in Appendix B. A County-wide program of HHW collection at the curb has the potential to significantly reduce toxic contaminants prior to composting, resulting in a high-quality compost product. As discussed in Appendix I, Cost Issues, variable rate programs have been shown to increase diversion rates and decrease the amount of waste generated in the residential sector. A more intensive public information program will be necessary to make these programs work. Table VII-1 shows the projected results of implementing these additional programs. These programs would be implemented incrementally, culminating in 2020. The residential sector diversion increases to 80.3 percent.

In the commercial and industrial waste generation sectors, jurisdictions would begin enforcement of the mandatory commercial/industrial recycling program requirements, and two new programs are recommended: (1) special waste management, and (2) commercial/industrial mixed waste processing. The latter program would require that all permitted solid waste transfer and disposal facilities have processing capability to divert recyclable materials from all commercial/industrial waste received. In other words, every waste management site would have a commercial/industrial materials recovery facility (MRF) equipped to recover recyclables from the mixed commercial/industrial waste stream. The special waste management program

complements the MRF program by removing from the mixed waste many of the substances that can contaminate recyclable materials. The level of public information, training and assistance [illegible] to be increased to implement these programs. Implementation of these additional programs, with their new facilities, will take some time. Therefore, Level 3 is projected to be fully implemented in 2020. Table VII-1 shows the projected diversion rate for the commercial sector would be 44.9 percent in 2000, and at full implementation in 2020, 67.8 percent. In 2000, the diversion rate is 51.9 percent for the industrial sector, increasing to 79.6 percent in 2020.

B. MARKET TRENDS

1. Introduction

The success of any recycling program depends on the security of the markets for recyclable products. A material can be recycled only if a market and/or an end use exist. This Section presents a general overview of the various types of markets for potentially recyclable materials, the types of recyclables in the waste stream, and the uses of recyclables as commodities. In addition, this Section addresses some of the trends that have influenced markets in the past and making some projections for the future. A more detailed discussion of the markets for individual materials can be found in Appendix J.

2. Recyclables as Commodities

For recycling to work, adequate markets must exist for all of the materials. Many communities have experienced setbacks in their recycling programs due to faltering of one or more markets. In these cases, separated materials may be stored, but most ultimately are landfilled. Successful recycling is therefore dictated by markets.

Recyclable materials separated from the waste stream become commodities, similar to the virgin materials used to make nearly every manufactured item. For example, aluminum beverage cans -- either flattened, baled, or shredded -- become a metal commodity similar to

aluminum produced from bauxite (ore). The recycled aluminum cans are essentially pure aluminum and can be used to manufacture all of the products manufactured using ore-derived aluminum.

The same type of relationship described above for aluminum generally exists between virgin materials sources and recyclable materials sources for the other recyclables, such as ferrous metals, paper, glass, and plastics. However, the relationship is not identical in all cases. For example, the equipment and processing requirements for making paper from virgin material (wood pulp) are different from those used for making paper from recycled paper. Consequently, a paper mill may have the processing equipment to handle only virgin material (i.e., wood pulp) and cannot use recycled paper as feedstock. For this type of mill, recycled paper is not interchangeable with virgin wood pulp. However, as noted earlier, a large number of paper mills in the United States have made or are making an investment in the capability to use either recycled or virgin feedstock. Thus, the total market for recycled paper exhibits the characteristics of a commodity market.

Commodities markets function worldwide and suppliers are indifferent about the destination of their commodities. The objective is to achieve the highest price (net of transportation costs). A corollary objective is that the market will be a repeat customer since the supplier needs continuing markets for commodities. Dropping one customer to supply another -- whether a domestic or foreign entity -- for a higher price, will not pay off in the long run if the new customer does not offer repeat business. The first supplier will be displaced by another supplier for the market that was dropped, and the first supplier may have difficulty reacquiring the original customer.

Many factors affect commodities markets, and thus the prices paid for recyclable materials. Domestic production and production capacity, imports, consumption, energy and transportation costs, changing technology, new product opportunities, and availability of substitute material are among the factors that affect markets for recyclable materials. International markets are affected by the same forces as well as by foreign trade tariffs, currency

exchange rates, trade policy and programs, and other political forces. All of these elements are expressed in the language of economists as the law of supply and demand.

Export markets for recyclable materials are large and active for the United States. Paper is a prime example. Greatly expanded recycling programs on the East Coast have generated more paper than regional mills can absorb. At the same time, the growing economies of the Pacific Rim countries demand fiber that cannot be produced locally, forcing importation of recovered paper from the United States and Europe. Paper is now the number one export (in annual tons) for the Port of New York. U.S. exports (all grades) of wastepaper for the period in 1994 was 7.7 million tons. This represents a 31 percent increase over 1993 and two years of declining exports.

The greater number of factors involved in export markets serve to increase the volatility of prices paid for recycled materials. It is important to understand that domestic marketers of recyclable materials must compete with export markets for the same materials. Domestic markets would rather not compete with export markets nor pay the higher prices bid by foreign competitors.

The factors that can increase prices can also drive them down, although the principles of economics will limit the lower end. Suppliers will no longer be willing to sell materials below a certain price. Once the price drops below the full cost of producing virgin material, recyclable material will begin to displace the raw material (where interchangeable). Furthermore, once domestic production requirements (demand) for recyclable materials are satisfied, suppliers will look for export markets. Many overseas markets have no domestic virgin material supplies to compete for the available demand.

All of the market forces discussed above combine to affect the value of recyclable materials. Prices offered for recyclables have shifted significantly in recent times -- some increasing, some decreasing. An important point to realize in secondary material markets is that future prices will be more or less than any current price. Accordingly, recycling programs should be designed to lessen dependency on day-to-day materials prices.

C. TRANSFORMATION FACILITIES

This Section focuses on existing transformation (waste-to-energy or WTE) facilities and opportunities for optimum operation. This Section provides recommendations regarding existing WTE capacity to the County of Los Angeles, and the rationale behind the recommendations.

A discussion of additional WTE capacity is also provided because waste combustion for energy (steam and/or electricity) generation presents a very real option for diverting non-recoverable waste from landfill disposal. However, given the potential for public opposition as well as difficulty in obtaining permits for additional emissions in the Southern California airshed, new WTE facilities located in the County or the expansion of capacity at existing facilities are not considered in calculating diversion from the waste stream for the purposes of this report.

1. Current Transformation Facility Capacity

Los Angeles County presently has two operating waste-to-energy facilities. Both facilities are of the mass-burn type, where the MSW is not processed into a fuel prior to combustion. These facilities are described below:

a. City of Commerce

This facility is owned by the Commerce Refuse to Energy Authority and operated by the L.A. Sanitation Districts. The Commerce facility began operations in 1986. Its design capacity is 380 tons per day (TPD), and it generates electricity. Air emissions control equipment includes a spray dry absorber to reduce acid gas emissions, a fabric filter to capture particulates and heavy metals, nitrogen oxide (NOx) controls, and continuous emissions monitoring. In addition, lime injection into the combustion unit is used to further reduce acid gases. The Commerce facility recovers 1,600 tons per year of ferrous metals from the facility ash. The present tipping fee at the City of Commerce facility is $30.00 per ton. The overall reported recycling rate for the City of Commerce in 1994 was 23 percent.

b. City of Long Beach

The Southeast Resource Recovery Facility (SERRF) is owned by a joint powers authority (L.A. Sanitation Districts and the City of Long Beach Inc.) is operated by Montenay Corporation. Operations began in 1988. The Long Beach facility's design capacity is 1,380 TPD and the facility generates electricity. Air emissions control equipment includes a spray dry absorber as well as a dry scrubber for acid gas control, NOx control, a fabric filter to capture particulate and heavy metals, and continuous emissions monitoring. Long Beach recovers 13,000 tons per year of ferrous metals from the facility ash. The 1995 tipping fee at the Long Beach facility is $27.50 per ton. The facility operator notes that 800 tons per week accepted from a transfer station contains a lot of dirt, lowering the heat value of the waste, and thus reducing the energy output of the facility.

Together, these two facilities have a rated capacity of 1,760 TPD on a seven-day per week basis (expressed as 1,760 TPD_7); in 1994, these facilities processed 1,686 TPD on a six-day per week basis (1,686 TPD_6).[20] Currently, the facilities report that they are operating at near capacity, but are threatened by relatively cheap landfill disposal capacity available in the region. For example, waste presently flowing to the Long Beach SERRF may be lost to the Orange County Landfill, which is offering disposal for a tipping fee at the $20.00 per ton level. Unlike landfill capacity that can be "banked" for future use, WTE capacity not used each day is lost capacity. Additionally, any low-heat value waste (such as the dirt-laden transfer station waste sent to City of Commerce), reduces the energy output of the facility and increases operating costs because of the lost revenues. Therefore, it is recommended that the County:

- develop policies and plans to fully utilize capacity at the two existing waste-to-energy facilities in the future; and
- develop policies to ensure that the waste delivered to the WTE facilities is combustible (i.e., not dirt).

[20]Based on 1994 annual tonnage data reported by the California State Board of Equalization.

2. Future Expansion and/or Additional Transformation Capacity

The DEIR/DEIS indicates that WTE alternatives were not considered because they "take material away" from diversion and recycling. This is no more true of WTE facilities than it is of landfills. Integrated waste management calls for planning a mix of alternatives. If Los Angeles County achieves 70 percent diversion in the year 2020, there will still be 10,000 tons per day of waste needing disposal. Four 2,500 TPD WTE facilities[15] would reduce the need for landfilling to approximately 3,000 TPD, taking into account the seven-day per week operation and 25 percent (by weight) ash generation of WTE facilities and would generate 280 mega watts of electrical power.

There is a total of 121 municipal waste-to-energy facilities operating in the U.S.[16] These WTE facilities are constructed using two entirely different technologies, mass burn and refuse-derived fuel (RDF). Mass burn WTE facilities accept mixed MSW into a storage area and feed this material directly into the furnaces for combustion. The heat generated is used to produce steam and electricity. Refuse derived fuel facilities have additional processing beyond receiving and storage. This processing usually includes removal of non-combustible materials and shredding the combustible portion to a uniform particle size. The shredded material, RDF, is reading to be fired directly into dedicated boilers or in combination with other fuels in existing boilers. RDF can also be compressed into pellets for easier storage and handling.

One advantage of the RDF approach is that the fuel can be prepared in a different location from the combustion site. RDF processing could be incorporated as part of the transfer station/MRF facilities contemplated for rail haul. RDF technology would allow location of combustion power plants outside the Southern California airshed, eliminating concern about the impact of WTE emissions in Los Angeles County.

[15]Ten thousand tons per day (10,000 TPD) 6 days per week converts to 8,571 on a seven day basis; sizing the facilities to be 85 percent available results in four facilities with a total rated capacity of 10,084 TPD. This was rounded to four 2,500 TPD facilities. The 2,500 TPD of ash generated 7 days per week would result in 2,917 TPD going to landfill 6 days per week.

[16]Integrated Waste Services Association (IWSA), *Municipal Waste Combustion Directory of the United States*, 1995.

A major opportunity is for existing coal-fired power plants to substitute refuse-derived fuel (RDF) for a portion of their coal feedstock. The logical choice of power plants would be those which supply some of the region's electrical power, such as the Southern California Edison Mohave plant in Nevada or the City of Los Angeles Intermountain plant in Utah.[23] Each of these plants burns approximately 12,000 TPD of coal and is accessible by rail. If they obtained 10 percent of their energy from RDF, these two plants would utilize about 5,000 TPD of RDF. This has been done by Northern States Power in Wisconsin and Minnesota, resulting in both lower air emissions and increased waste management capacity, while maintaining power output.

Expansion of the two existing WTE facilities is a possible future option for Los Angeles County; however, there are several reasons for not entertaining this option at the current time. First, the facilities must compete with relatively cheap landfill prices in the region. Expansion should have the effect of lowering their per-ton operating costs on a per-ton basis (since adding a new line or two is lower-cost than building an entire new facility), but it is unlikely that they could reach the $20/ton tip fee and without endangering the financial stability of the facilities. There is enough challenge in maintaining waste flow for current capacity. Second, expansion could mean renegotiating their power agreements with Southern California Edison, and the new power purchase rates would be much lower than present rates. Both are presently receiving $0.13 to 0.14 per kilowatt hour (kWh) with a floor price of $0.09/kWh. New rates would be about $0.01 to 0.02/kWh, which would force tipping fees up to $85 to $100/ton.

Potential environmental and human health impacts of waste-to-energy have received considerable attention from the media and from the environmental activist community in recent years. What has not been made clear in this dialogue is that WTE is a cleaner power generator that the two primary sources of electricity in the U.S., e.g., coal and oil. Further, WTE air emissions only slightly exceed natural gas (the cleanest-burning fossil fuel) in the amount of pollutants emitted per unit of energy produced. A detailed side-by-side health risk analysis that compares a new landfill with a mass burn waste-to-energy plant "...shows that WTE plants may

[23]*Electric Power Monthly*, Energy Information Administration, U.S. Department of Energy, November 1995.

be a better choice than landfills for minimizing health risks and environmental effects."[24] Finally, WTE does not present the potentially grave environmental and health impacts associated with [illegible].

A recent article in *Environmental Health Perspectives*[25] prepared by scientists and health professionals from the University of North Carolina at Chapel Hill, the U.S. EPA, and Mecklenburg County Health Department, reports on the first year of a three-year study of air quality and respiratory function and symptoms in six communities. Three of the communities have waste combustion facilities (one municipal solid waste-to-energy facility, one biomedical incinerator, and one liquid industrial hazardous waste incinerator). Each of these three communities were paired with comparable communities that do not have such facilities, for a total of six study sites. The article notes that results of the first year air monitoring showed, "(d)irect measurements of air quality and estimates based on a chemical mass balance receptor model showed that incinerator emissions did not have a major or even a modest impact on routinely monitored air pollutants." Similarly, the results of the epidemiological surveys showed that, "(a) one-time baseline descriptive survey (n = 6963) did not reveal consistent community differences in the prevalence of chronic or acute respiratory symptoms between incinerator and comparison communities, nor did we see a difference in baseline lung function tests or in the average peak expiratory flow rate measured over a period of 35 days." In conclusion, the article abstract notes, "(b)ased on this analysis of the first year of our study, we conclude that we have no evidence to reject the null hypothesis of no acute or chronic respiratory effects associated with residence in any of the three incinerator communities."

Southern California receives electrical power from a variety of primary as well as alternative energy sources. Major primary sources include coal-fired out-of-State power plants

[24]"Comparing Air emissions from Landfills and WTE Plants," Kay H. Jones, *Solid Waste Technologies*, March/April 1994.

[25]Carl M. Shy, et al., "Do Waste Incinerators Induce Adverse Respiratory Effects? An Air Quality and Epidemiological Study of Six Communities," *Environmental Health Perspectives*, Journal of the National Institute of Environmental Health Sciences, V. 103, No. 7-8, pages 714-724, July-August 1995.

as discussed above. Alternative sources include hydropower (from Hoover Dam), wind energy, and some experimental solar salt ponds at the Salton Sea. As L.A. County's population continues to grow, electrical service requirements will also continue to grow. New power capacity will be developed to meet this demand. Some or all of this demand could be met by conservation measures in the near term; however, sufficient conservation is unlikely under present legislative and regulatory structures. Because of the significant line losses experienced when transmitting power long distances, development of local power generation capacity is preferable to wheeling power in from outside the Los Angeles area.

New electrical power source options include new or expanded facilities based on fossil fuels (coal, oil, and natural gas). Coal and oil, in particular, would be difficult to justify given the air pollution concerns in the Southern California Air Quality Management District (SCAQMD). Siting a nuclear power plant is also problematic due to concern about possible earthquake damage to reactor containment (e.g., Diablo Canyon).

Expansion of existing alternative energy facilities or development of new ones is also limited. There are no rivers of sufficient year-round flow volume in Southern California that can provide additional hydropower from dams, not to mention the significant environmental impacts that result from damming up rivers to fill canyons. Both windpower and solar salt pond locations are relatively remote from populated areas, so long-distance line transmission would be required if these sources are expanded. Expansion of the wind farms in the desert near the Little San Bernardino Mountains is likely to encounter opposition from the growing desert cities (Palm Springs, Rancho Mirage, Desert Hot Springs, Palm Desert, etc.), as vast areas of (potentially subdividable) desert are already dedicated to wind farms. Solar technologies, including salt ponds, are still considered developing technologies, and have cost as well as technical limitations to their application.

Another developing technology that may become available for future power generation in Los Angeles County is pyrolysis (gasification) of municipal solid waste or selected feedstocks from the waste stream (e.g., tires). This technology breaks down the organic components of the waste into combustible gases, char, and oil by exposing the feedstock to high temperatures

in the absence of oxygen. Pyrolysis has been demonstrated under various private and federally-sponsored research projects; however, no successful commercial applications exist to date. However, in the 50-year planning period considered by the County, maturation and application of this technology is a reasonable possibility.

In conclusion, waste transformation technology is a viable option for future application to two problems that need to be addressed in Los Angeles County: diversion of municipal solid waste from landfill disposal, and generation of electricity to meet new population demands.

VIII. NEW PROJECTIONS FOR DISPOSAL DEMAND

Chapters IV through VII identify flaws in the design and calculations used by the County in the DEIR DEIS and Siting Element "time-to-crisis" projections for the Los Angeles County solid waste disposal system. Each chapter highlights a portion of these projections, and provides an alternative projection, oftentimes supported by Los Angeles County government documentation. The strategy presented in this chapter includes all of the projection alterations, except landfill expansion, made in Chapters IV through VII. The alterations include the utilization of the following:

- closing of the BKK and Lopez Canyon landfills in 1996;
- increased waste exports;
- inert landfill capacity;
- waste-to-energy facilities in Los Angeles County;
- all operational Class III landfills in Los Angeles County;
- historically justified waste disposal rates;
- foam as an alternative daily landfill cover; and
- aggressive (but obtainable) recycling diversion rates.

Two different scenarios were run with the waste materials flow model to illustrate the impact of the intensive recycling and diversion strategy that is recommended for Los Angeles County. These are:

Scenario 6A: Achievement of a 70 percent diversion goal for all 88 cities and the County in the residential, commercial, and industrial sectors. This is targeted for achievement in 2020, the same schedule as the City of Los Angeles.

Scenario 6B; A strategy of diversion through landfill bans for corrugated board (cardboard), wood and yard waste. A landfill ban on all recyclable materials would accelerate this strategy; however, bans on these three illuminate this strategy's effectiveness.

Both of these Scenarios build on the strategies recommended and illustrated in the first five Scenarios as discussed in Chapter V. However, both are mutually exclusive -- that is, they are not combined into a single model run. In actuality, an intensive diversion and recycling strategy would employ the 70 percent goal and landfill bans for recyclable materials. In addition, this strategy must include a wide variety of diversion programs and facilities for processing materials banned from landfills. These facilities range from MRF's, such as the 4,400 TPD facility planned for Puente Hills with a 15 percent diversion, to the 1,000 TPD Bio Gro/Wheelabrator facility with diversion close to 100 percent. The full program recommended for the County is outlined in Chapter VIII and technologies discussed in Appendix B.

Scenario 6A: Total County 70 Percent Diversion

This Scenario assumes that all the cities, in addition to the City of Los Angeles and the County unincorporated area as discussed in Scenario 4, achieve 70 percent diversion in 2020. This would mean the cities, which represent 53 percent of the waste generated in the County, adopt and implement this 70 percent diversion goal.

This option does not have any impact until after the year 2000. Starting in 2001, the impact is to increase the diversion of the entire County by one percent per year and to extend the Shortfall by two years compared to Scenario 5, to 2016. This can be seen in Figure VIII-1. The amount of the Shortfall is 3,500 TPD in 2016, and increases to 10,000 in 2023. Further reductions, in excess of 5,000 tons per day (TPD), occur in subsequent years, as can be seen by comparing Figure VIII-1 and VIII-2.

Scenario 6B: Recyclable Material Bans

Most recycling and diversion programs target specific materials in the waste stream. The programs in Los Angeles County are no exception. Table VIII-1 lists these materials, along with the fraction of the County waste stream which they constitute. These materials total 57 percent of the waste disposed. Table VIII-1 also shows the estimated quantity of each of these materials disposed in landfills in 1995. It is recognized that the composition of the waste stream has

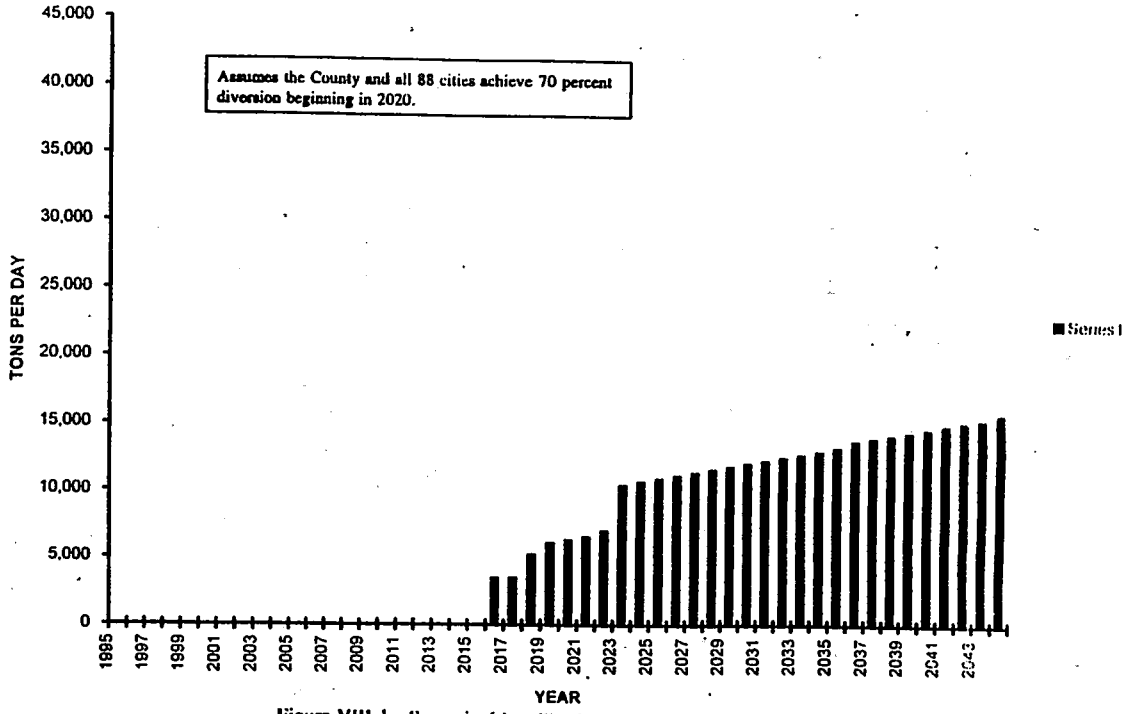

Figure VIII-1. Scenario 6A -- Total County 70 Percent Diversion
Los Angeles County Disposal Need

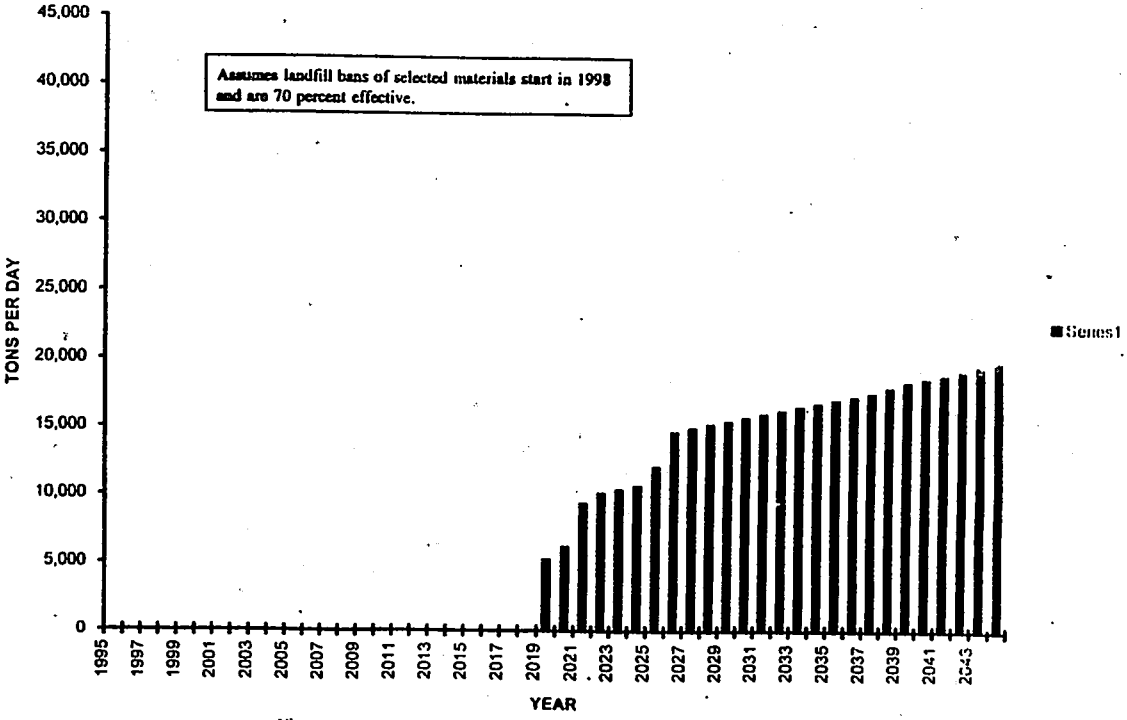

Figure VIII-2. Scenario 6B -- Landfill Bans of Selected Recyclables
Los Angeles County Disposal Need

changed since the 1990 SRRE's and the CIWMB Interim Database, the source of this data. These changes in subsequent waste composition are caused by changes in products in the marketplace. For example, the weight of individual glass and metal containers has decreased

Table VIII-1. Los Angeles County
Estimated Average Waste Composition of Selected Recyclable Materials

Waste Categories & Types	Composition As Disposed (%)	1995 Quantities Disposed (Tons)
Cardboard & Bags	8.3	868,241
Mixed Paper	11.7	1,223,906
Newspaper	5.1	533,498
Hi-Grade Ledger Paper	2.0	209,215
HDPE Containers	1.0	104,607
PET Containers	0.3	31,382
Recyclable Glass	3.0	313,822
Aluminum Cans	0.3	31,382
Ferrous & Tin Cans	3.9	407,969
White Goods	0.3	31,382
Yard Waste	12.7	1,328,513
Wood	8.8	920,545
TOTAL:	57.4	6,009,462

Source: CIWMB Interim Database Project, revised August 4, 1993.

in the last six years, and material substitutions in products, such as plastics for metals and glass, have changed the relative concentrations of these materials. In addition, the waste stream composition is altered by diversion. For example, diversion of all newspaper would result in an increase of the percentages of all other materials. Because of these changes -- and the fact that landfill bans, even when enforced, are never 100 percent effective -- not all of these banned materials will be diverted. To account for these factors, it is assumed in this Scenario that 70 percent of these materials will be diverted due to the landfill bans.

For this Scenario, the three materials (corrugated, wood and yard waste) shown in Table VIII-1 are banned from landfill disposal, beginning in 1998. These constitute 8.8, 8.3 and 12.7 percent, respectively, of the waste disposed (or approximately 30 percent total). The ban is

assumed to be 70 percent effective, allowing 30 percent of the banned material still to be landfilled. This strategy illustrates the effectiveness of immediate action on the part of the County. It postpones the Daily Disposal Shortfall until 2019, a gain of five years over Scenario 5 (Chapter VII). This is shown graphically in Figure VIII-2. Every year of delay in the implementation of this and other diversion strategies results in loss of landfill capacity. This capacity is difficult to replace.

As the model Scenarios illustrate, intensive recycling and diversion is an effective strategy for managing waste and conserving landfill space. Applying landfill bans to all the recyclable materials referred to in Table VIII-1 and developing recycling programs for these materials in the residential, commercial, and industrial sectors will further reduce the need for landfills in the County. The sooner this strategy is implemented, the greater its impact will be.

IX. LANDFILL EXPANSION POTENTIALS (SCENARIO 7)

The solid waste management strategies discussed in the previous chapters clearly will eliminate the need for additional in-county landfills in the short term (AB 939, 15 year planning period), if implemented. In the long term, The County and the 88 Cities will need to implement additional solid waste management strategies. After implementing all the strategies discussed the County and the Cities will have some 15,000 to 20,000 tons per day of waste to manage. A number of alternatives have been discussed but not included in the projections, including additional export (rail haul and remote landfilling), refuse derived fuel burned in existing coal fired powerplants, and composting. Expansion of existing in-county landfills is examined but not recommended in the following paragraphs.

Potential landfill expansions and closures play a large role in identifying the "time-to-crisis" for Los Angeles County. Depending on what is assumed with regard to expansions and closures, projections will indicate no crisis or a crisis in the next year. Projections in Table V-1, which were used in the Elsmere Canyon DEIR/DEIS, neglect the expansion potential of the landfills, which is an important factor in identifying a more realistic "time-to-crisis." In the Siting Element, six existing landfills were projected to expand and four new ones developed. It is true that there is no guarantee that permits will be renewed and extensions may be contested; however, the vast majority of landfill permits are extended, making this scenario the most probable outcome. Table IX-1 provides current and potential capacities for the landfills in Los Angeles County. All of the information in Table IX-1 is taken from reports generated by the Los Angeles County Department of Public Works.

In the Siting Element, the County suggests a scenario in which six landfills are expanded to their physical capacity. These are: Antelope Valley[20], Chiquita, Lancaster, Lopez, Puente Hills and Sunshine. In addition, the County shows the opening of four new landfills: Blind, Elsmere, Mystic/Rustic-Sullivan, and Towsley. This scenario results in a surplus of landfill capacity in the County through the planning period. The surplus is over 50,000 TPD at the end

[20]Antelope Valley has been issued a revised permit that increases daily disposal capacity to 1,400 TPD.

Table IX-1. Current and Potential Disposal Capacities for the Los Angeles County Landfills

Landfill	Permitted Disposal Capacity[1] (TPD)	Average Daily Disposal 1994	Total Permitted Capacity (million tons)[1]	Total Expanded Capacity (million tons)
Puente Hills	12,000	10,945	33.0	67.4[2,3]
Spadra	3,700	2,156	2.81	2.81
Scholl Canyon	3,400	1,587	11.5	11.5
Bradley	7,000	4,448	3.91	8.91
Sunshine Canyon	6,600	0	17.0	100.0[2]
Chiquita Canyon	5,000[4]	1,692	2.31	32.31[2]
Calabasas	3,500	2,975	12.6	12.6
Brand Park	102	18	0.6	0.6
Antelope Valley Dump	750	539	2.3	2.3
Azusa Land Reclamation	6,000	695	3.5	3.5
Burbank	240	162	6.4	6.4
Lancaster	1,000	435	0.66	0.66
Pebbly Beach Disposal	33	4	0.044	0.044
Whittier-Savage Canyon	350	217	2.73	2.73

[1]Draft table, "Remaining Permitted Combined Disposal Capacity of Existing Solid Waste Disposal Facilities in Los Angles County as of January, 1995," Los Angeles County Department of Public Works, March, 1995.

[2]"Expansion of Existing In-County Waste Disposal Sites and Projected Disposal Needs," Los Angeles County Department of Public Works.

[3]Based on the calculation of 12,000 TPD x 312 days/year x 18 years (1995 to 2013) = 67.4 million tons.

[4]After expansion, the permitted daily capacity will increase to 10,000 TPD.

of the 15 year planning period, in 2010. In fact, the County's scenario of landfill expansion would result in excess landfill capacity in the County even without the new landfills.

This section (Scenario 7) examines a more modest landfill expansion strategy, where five landfills are expanded. Lopez and BKK have been dropped from the expansion list because they are scheduled to close in 1996. Also, this strategy reduces the size of the expansions of the five landfills. The values for expansion are as follows:

Antelope Valley	5.3 million tons
Chiquita	17.0 million tons
Lancaster	5.7 million tons
Puente Hills	50.0 million tons
Sunshine	60.0 million tons

These values for expansion were calculated by taking the difference between the total physical capacity and the present Total Permitted Capacity, dividing this potential increase in half, and adding this increase to the remaining Permitted Capacity. This value was then rounded.

This strategy is effective after the strategies described in Scenario 1 through Scenario 5 in Chapter V are implemented, as is the landfill conservation strategy discussed in Chapter VI. Intensive recycling and diversion described in Scenario 6 are not activated. The strategy in this Scenario postpones the "time to crises" to 2023, well beyond the AB 939 required planning period. Further, the Shortfall, when it does occur, is not severe, starting at 800 TPD and increasing to 10,000 and growing slowly thereafter. This is shown graphically in the chart in Figure IX-4.

Los Angeles County Disposal Need

X. RECOMMENDED COUNTY ACTIONS

This Chapter draws upon preceding Chapters to establish the County's potential for a leadership role, as well as pointing out direct actions presently within the purview of the County government. Recommendations cover:

- Changes to the County structure that will foster a policy shift to diversion/transformation as the preferred methods for addressing solid waste, and
- Specific, practical applications.

Sections within the Chapter, where appropriate, estimate the amount of diversion that can be accomplished by implementing a particular recommendation.

The estimated cost of implementing a recommended plan is normally developed as part of the planning process. Because this report has been developed without County input, however, there are many unknown cost factors that make estimation of overall costs a misleading exercise. Some critical cost issues are discussed in Appendices E and I. It should also be noted that cost is not the deciding factor in determining the level of implementation for solid waste diversion programs; State law and federal EPA guidelines make it clear that source reduction/recycling are the preferred modes of managing solid waste, whether it is cheaper in the short run or not. Further, the guidelines for Environmental Impact Statements require consideration of alternatives without regard to cost.

A. USE OF COUNTY SOLID WASTE TASK FORCE

The Los Angeles County Solid Waste Management Committee (the Committee) has been in the forefront of solid waste planning for years. With the passage of AB 939, the Committee was given the task force responsibility as required under this legislation, by the County. The Committee has provided policy guidance for the Los Angeles County Board of Supervisors. Also, the Committee is responsible for coordination of solid waste management issues on a county-wide basis. The Committee has failed to develop a policy direction for the County that focuses on alternatives to in-county landfills.

Recommended County Action

The Board of Supervisors should reconstitute the Committee and give the reconstituted Committee the charge of developing diversion-oriented policies for the County.

B. WASTE DISPOSAL PRACTICES OF COUNTY DEPARTMENTS

Waste from government-owned and/or operated facilities can be a substantial portion of the municipal waste stream. This waste often goes unnoticed because it is considered "commercial waste" in traditional waste composition studies. However, where localities have conducted an analysis of that portion of the commercial waste stream attributable to government operations, the results can demonstrate significant opportunities for government diversion activity. For example, in the City of Los Angeles, an estimated 2.3 million tons of the total waste generated in 1995 was under City control and 29 percent of this was generated by government agencies.

Los Angeles County Public Works Department should seek assistance from other County Departments in achieving AB 939 goals and extending the life of in-County landfills. This is particularly important in light of the increased emphasis being placed in the County on commercial and institutional recycling rates and the expansion of residential curbside programs to include mixed paper and yard trimmings. All County agencies should be responsible for achieving 50% or greater recycling rates as well, including county offices, health facilities, prisons, parks and recreation facilities, maintenance facilities, etc.

Clearly, County Public Works does not have the authority to require such diversion activity from other County agencies. However, it can, and should, use its position to gather and analyze data, track recycling rates, and make recommendations to the County Board of Supervisors, which can then direct each individual agency to institute and report on diversion activities.

The ancillary benefits of such an approach are also substantial. Agencies are often unaware of their solid waste costs, focusing on diversion will result in significant source reduction as well as recycling. These efforts will produce cost savings to the generating agencies.

The County should recommend that the Board of Supervisors require the following of each County agency:

1. Commit to 50% recycling rate by 1998 and 65 percent by 2000.
2. Develop a plan to achieve these diversion rates, with year to year goals.
3. Prepare a report in 1996 that contains the following information:
   a. Describe how solid waste for the agency is picked up and disposed (agency employees, contracts with haulers, etc.)
   b. Provides a cost estimate for disposal (total and cost per ton)
   c. Describes service level utilized (number of containers, size of containers, frequency of pick-ups, etc.)
   d. Estimates the tons/year disposed of by the agency.
4. Prepare a report in 1996 that summarizes agency recycling activity, if any, and quantifies the cost, cost/benefit of those programs.
5. Submits quarterly narrative reports to the Department of Public Works, which are then summarized and included in DPW's Quarterly Report on the Action Plan to the Board of Supervisors.
6. Submits annual reports to the Board of Supervisors on status of recycling programs, including quantification of diversion rate.

The County Sanitation Districts of Los Angeles County (Sanitation Districts) operate two buy back/drop off centers for the general public: one at the Puente Hills Landfill and the other at the Palos Verdes Landfill in Rolling Hills Estates. The Palos Verdes Recycling Center opened in November 1977 and the Puente Hills Recycling Center opened in October 1982. Customers can receive money for their recyclables or "donate" them to a designated charity.

These are in addition to the four active landfills, a transfer station, three landfill gas-energy facilities, and the Commerce waste-to-energy plant operated by the Sanitation Districts.

Since their opening, both facilities have added materials to the list of recyclables accepted from the public and currently both accept glass in three colors, aluminum, steel, PET and "other plastic" containers, and newspaper. Over time, each facility gradually increased tonnage and customers and then began to experience a decrease in both tonnage and customers. For example, the Puente Hills Recycling Center started in 1982 with 424 customers bringing in 36 tons, grew to 7,499 customers bringing in 376 tons in 1991, and then dropped to 180 tons received from 4,535 customers in 1994. Similarly, the Palos Verdes facility accepted 449 tons from 4,627 customers in 1997, grew to 4,597 tons from 23,914 customers in 1991, and dropped to 689 tons from 16,688 customers in 1994. While some of this drop in the quantity of materials can be attributed to the initiation of curbside programs throughout the County, some of this drop is due to a lack of public information and promotion.

Both facilities could assist in the achievement of County-wide goals by filling gaps in curbside service and by encouraging residents and small businesses to drop off source separate materials for free as a means of avoiding disposal charges. The easily recycled materials, including corrugated cardboard, magazines, office paper and mixed paper, should certainly be added to the materials accepted by the centers. Harder-to-recycle materials, including white goods, tires, batteries, separated construction and demolition waste, and wood, should also be accepted. In addition, a drop-off site for clothing and small durables could be added in cooperation with a charitable organization. Information could be distributed at the site regarding other opportunities to divert materials in Los Angeles County. Through this and other types of activities, the Sanitation Districts could fill voids in County diversion services and increase overall tonnages diverted County-wide.

Recommended County Actions:

It is recommended the Sanitation Districts expand the drop-off system. This should include expanding the material accepted as discussed above and increasing the number of sites. The Sanitation Districts own and/or operate some 20 facilities throughout the County. An expanded citizens drop off center should be located at each of these facilities, if practical.

The Sanitation Districts should adopt and implement the 65 percent diversion goal for its facilities (offices and plant as applicable), as discussed above.

C. UNINCORPORATED AREA ACTIONS

Based on Los Angeles County's AB 939 disposal surveys, the unincorporated area of the County landfilled 211,057 tons of waste per quarter, compared to 2,923,059 tons landfilled from all localities in the County. This represents 7.22% of Los Angeles County landfilled waste, a substantial portion of County landfill usage. Overall, County quarterly disposal reports indicated that solid waste facilities in the County received a total of 289,010 tons of waste from the unincorporated area, compared with 3,756,290 tons from all Los Angeles County localities, or 7.7% of the total. The latter includes tons salvaged, transformed, landfilled and used as ADC in solid waste facilities in the County.

Los Angeles County Department of Public Works has a unique opportunity to both extend landfill life and to provide a leadership role in demonstrating diversion opportunities through its management of waste collection systems in the County unincorporated area. Therefore, it is recommended that Los Angeles County use the unincorporated area as a demonstration for intensive recycling and diversion. To do this the County would need to implement the Level 3 Maximum Diversion program described in Chapter VII.

Recommended County Actions:

Los Angeles County should implement the maximum diversion program. To initiate this program it is recommended that the County:

- Make a formal announcement to adopt the program;
- Adopt a 70 percent diversion goal for the unincorporated area;
- Establish a program team to develop a detailed plan and implement;
- Establish an enterprise fund administration and accounting system for solid waste in the unincorporated area solid waste system and fund it.

D. MANAGEMENT OF COUNTY BIOSOLIDS

The Sanitation Districts collect and treat wastewater for 78 cities and unincorporated areas in Los Angeles County. The Sanitation Districts operate 11 wastewater treatment facilities with a combined daily flow of more than 500 million gallons. Seven of the facilities are located in the metropolitan area of Los Angeles County, two in the Santa Clarita Valley, and two in the Antelope Valley.

The largest of the facilities is the Joint Water Pollution Control Plant located in the city of Carson. Approximately 1,250 wet tons of biosolids are generated at this facility daily. Total wet tons for 1994 were 473,200. Wastewater treatment for the Santa Clarita Valley is conducted at the Saugus and Valencia Water Reclamation Plants and solid generated during treatment are processed at the Valencia facility. A total of 20,000 wet tons of biosolids were disposed of in 1994 at the Chiquita Canyon Landfill. The Antelope Valley facilities include the Lancaster and Palmdale Water Reclamation Plants. Approximately 20 wet tons are produced daily from these facilities, where anaerobically digested, dried biosolids are intermittently released for soil amendment material. For example, the Antelope Valley biosolids have been used in agriculture, for landscaping at the Mira Loma Jail, and to revegetate perimeter slopes at local landfills.

Despite contracts for composting, land application, and Nox reduction in cement kilns, some 3,000 wet tons per week are sent to Puente Hills Landfill from Los Angeles County, out of a total of approximately 9,600 tons per week produced by all County-operated facilities. At an average of 500 tons per day (TPD) disposed in Puente Hills Landfill (6 day week), biosolids utilized almost 4% of Puente Hills daily capacity (13,200 TPD) and 4.6% of the average daily tonnage disposed of at Puente Hills in 1994. This was mentioned in Chapter VII and represents a significant usage of Puente Hills capacity which could be utilized to either extend Puente Hills' landfill life or to accept residential and commercial waste in the future which would otherwise have to be disposed of at out-of-County or out-of-state landfills.

Recommended County Actions:

The Sanitation Districts should institute a policy of 100% composting, land application and NO_x reduction in cement kilns for all County-generated biosolids, with Puente Hills Landfill disposal utilized only as a backup when other alternatives fail in an emergency.

Since sludge was not calculated in the AB 939 aggregated County tonnages, this means that the 500 TPD of material sent to Puente Hills shows up County-wide as an increase in disposed waste over 1990 in the disposal surveys done for AB 939 compliance in 1995. While it is not certain, the small amount shown in the CIWMB interim database was probably as a result of the City of Los Angeles disposed tonnage.

E. MANAGEMENT OF COUNTY LANDFILLS

Landfills in Los Angeles County can be managed to maximize diversion and conserve landfill capacity. The start for this approach would be the adoption of a policy by the County that recognizes that land for urban landfills is a scarce and diminishing commodity. The current landfill tipping fees do not reflect this fact; however, it is demonstrated by growing public objection to new and existing landfills. The County policies should reflect this problem, and take concrete action. The recommendations offered in this Section are some of the actions the County could take.

First, the County should implement Item 5 of the 1988 Action Plan, direct billing for collection and disposal of solid waste. To be most effective, this billing should itemize the various components of the cost: recycling, yard waste, solid waste collection, disposal, etc. The basis for this must be full cost accounting, utilizing an enterprise fund as discussed in Appendix E. The coupling of direct billing with a variable rate structure based on weight or volume has been shown to reduce total generation of waste and to increase diversion in communities that use this approach. A variable rate structure is applicable to both residential and commercial wastes. Currently, larger U.S. private haulers are implementing weight-based systems using scales on their trucks to weigh each container as it is dumped. They are finding that the cost of the system, about $10,000 per truck, is paid for by more accurate billing of generators based upon weight the same way the hauler pays by weight at the landfill. The City of Seattle Case Study provided in Appendix A describes the application of a variable rate system to a residential integrated waste system.

As discussed in Chapter V, prohibiting landfill disposal of specific materials is effective in achieving diversion. Enforcement of bans for such materials as yard waste, white goods designated recyclables, and so on cannot be 100 percent effective for a variety of reasons, as discussed in Chapter V. However, if 70 percent effective, bans would reduce the material being landfilled by approximately 21 percent.

It is recommended that a chemical foam system be adopted as the daily cover method used by all the landfills in the County. This alternative landfill management technique is discussed in Chapter VI. Included as part of this is the recommendation that shredded yard waste no longer be permissible as alternative daily cover. Implementation of this recommendation will increase the capacity of all the landfills by 25 percent (i.e., the space taken up by the use of dirt and other cover materials such as shredded yard waste).

Technology discussed in Chapter VI is under development to accelerate the breakdown and stabilization of the mainly organic material in landfills using shredding, moisture adjustment and leachate recirculation. Los Angeles County could initiate a development project to demonstrate the effectiveness and cost of the approach. This would involve implementing this

management technique in one operating landfill and collecting data on operational and cost elements. If successful, accelerated biostabilization has the potential to double the capacity of existing landfills, based upon the Albany, New York experience.

Recommended County Actions:

- Implement direct billing of a variable rate based upon full cost accounting in the unincorporated areas. It is also recommended that the County meet with the Cities to develop cooperative methods to implement similar systems in all jurisdictions in the County. It is recommended the County and the Cities pass ordinances to require similar billing by private haulers and that the data collected be part of a periodic reporting requirement.

- Prohibit the disposal of the following materials in all public and private class III landfills in the County: materials designated for recyclable collection, yard waste, white goods, tires, vehicle batteries, inert materials, wood, and biosolids.

- Encourage the adoption of foam (or tarp) daily cover in lieu of dirt or green waste alternative daily cover at all landfills in the County. The County could initiate a demonstration program at one landfill to test effectiveness of various products, and provide a site for training public and private landfill staff.

- Prohibit the use of shredded greenwaste as alternative daily cover.

- Initiate a demonstration project for accelerated biostabilization of landfilled organic wastes, documenting costs and experiences, and providing training to other landfill owners and operators.

- Require all commercial/industrial waste disposal to be MRF-processed, at transfer stations or at the landfill sites.

- Develop commercial/industrial waste Materials Processing Facilities (MRFs) at landfills located in the County, as discussed in Chapter VII. MRFs may be publicly-sponsored, private enterprises, or joint efforts.

F. MANAGEMENT OF TRANSFORMATION FACILITIES

While the County does not have direct control over the operations of two existing waste-to-energy (transformation) facilities in the County, the Sanitation Districts have direct participation in both facilities. The 380 TPD City of Commerce facility is operated by the

Sanitation Districts. In the case of the Southeast Resource Recovery Facility (SRRF) in the City of Long Beach, the Sanitation Districts entered into a Joint Powers Authority (JPA) agreement; this JPA owns the SERRF in Long Beach. In addition, the County has the power to direct waste from County-operated transfer stations and through County waste collection contracts to these two facilities.

It is recommended that the County:

- In consultation with the operators of the Commerce and Long Beach facilities, direct waste from County-operated transfer stations to the waste-to-energy facilities in amounts sufficient to maintain MCR (maximum continuous rating) at each facility;

- Manage incoming wastes at transfer stations so that largely non-combustible loads are diverted to landfill or inert landfill disposal rather than transferred to the waste-to-energy facilities;

- As feasible, require combustible waste collected by the County or by private haulers under County contracts be delivered directly or via transfer stations to the two waste-to-energy facilities; and

- Work with the two cities and the Sanitation Districts to explore potential for expanding capacity of the two facilities to meet permitted limits (3,230 TPD).

G. MANAGEMENT OF COUNTY TRANSFER STATIONS

In 1994, the County of Los Angeles reported that approximately 19 transfer stations were operating in the County.[21] Transfer stations are used by individual communities or solid waste collection firms to optimize their transportation costs. This is accomplished by limiting the use of small collection trucks to picking up wastes from the generators and transferring the waste to more efficient transfer trailers for long-distance hauling to the disposal site. Due to the fact that transfer stations are sited to reduce collection truck route distances, they are designed to serve a defined area and generally range in size from 500 to 3,000 TPD.

---

[21]County of Los Angeles, Department of Public Works, Waste Management Division, *Nondisposal Facility Element*, March 1994.

Many private transfer stations perform some "dump and pick" operations to recover high grade materials. These operations have little specialized equipment, using a front-end loader and laborers to separate the materials on the tipping floor. The diversion rate for this type of operation ranges from zero to ten percent of the incoming waste. More technically advanced transfer station recovery systems are called mixed waste processing facilities (MWPFs). A minority of the 19 transfer stations in the County have invested in separation equipment to actively process all or a portion of the waste stream and can be classified as MWPFs. Based upon data from facilities surveyed by GAA,[22] the recovery rate for these facilities ranges between 8 and 30 percent of the incoming waste stream. Only one of the 19 transfer stations in the County exceeds 30 percent and processes a significant waste quantity.

In contrast, the 950 TPD MWPF owned by the City of Sunnyvale and operated by Western Waste diverts 46 percent of the incoming waste. This facility operates on a mix of 25 percent residential waste and 75 percent commercial waste. Some source separation takes place prior to collection of the waste delivered to the MWPF. The Sunnyvale MWPF recovers 12 grades of paper, all six plastic resin categories and other plastics, metals, glass, tires, batteries, white goods, waste oil and household hazardous waste. To achieve diversion at this scale, a substantial investment in building and processing equipment must be made. The Sunnyvale facility cost in excess of $23 million. In addition, the waste stream coming into the facility must be managed to facilitate recovery of the separate materials. This means not only segregating waste loads on the tipping floor, but modifying collection routes to reduce contamination of recoverable materials.

Transfer station planning for the future in Los Angeles should incorporate rail transfer for waste and recyclable materials in the siting and design stages. While this will tend to make the facilities larger due to the capital investment necessary, the advantages are more than off-setting. The first advantage is the reduction in truck traffic achieved by using rail transport instead of long-haul transfer trailer trucks. Second, the air emissions of a rail haul system are

[22]Eileen Brettler Berenyi, *the Materials Recycling And Processing Industry In the United States, 1995-96 Yearbook)*, Government Advisory Associates, Inc., 1995. —

significantly less than long-haul trucks, a new landfill, or a waste-to-energy facility.[23] These factors combined with the difficulties of siting large landfills in an urban area where available, [illegible] haul an attractive option. The Sanitation Districts are planning a rail haul transfer system based at the Puente Hills landfill,[24] that would include recovery of materials from the tipping floor prior to transfer (the Puente Hills Materials Recovery Facility), but no implementation has been initiated. It is possible to implement this MWPF in stages. The Sanitation Districts could construct the basic transfer building and implement the diversion activities immediately. Rail spur construction and intermodal transfer equipment could be added at a later time when closure of Puente Hills is imminent. Intensive materials recovery at the proposed Puente Hills MRF could equal the 46 percent diversion accomplished by the City of Sunnyvale MWPF discussed above.

Given the advantages discussed above, why hasn't rail haul been implemented in Los Angeles County? Part of the answer is the lack of full cost accounting for solid waste in the County. For example, the DEIR/DEIS[25] compares the estimated cost of rail haul ($50 per ton) to the estimated cost of landfilling ($20 per ton) at the proposed Elsmere landfill and concludes that the cost differential is too high. This, despite the presentation of information in the DEIR/DEIS that over 75 percent of the waste will arrive in transfer trucks. No cost for these transfer operations was considered.

The 19 transfer stations have a permitted capacity of approximately 20,000 TPD or 57 percent of the 1995 disposal requirement. The cost of transfer, which averages between $15 and $25 per ton, should be added to the disposal cost of most of the waste going to landfill to make any comparison of feasibility. The lack of a direct billing or full cost accounting system for solid waste obscures this issue.

[23]*The Feasibility of Hauling Solid Waste from the San Gabriel Valley to Remote Disposal Sites*, Southern California Association of Governments (SCAG), April 1988.

[24]*Intermodal Facility and a Waste-by-Rail Disposal System Originating from the Puente Hills Materials Recovery Facility, Draft Environmental Impact Report*, Sanitation Districts of Los Angeles County, December 1994.

[25]Page 3-20, DEIR/DEIS. —

Recommended County Actions:

- Encourage County Sanitation Districts to begin construction and operation of the proposed Puente Hills Materials Recovery Facility including rail transfer capability as soon as possible;
- Transfer haul combustible loads, as necessary, from the County's transfer facility, and assist in negotiating agreements for transfer of combustible loads from the proposed Puente Hills MRF and existing transfer facilities, sufficient to keep the two waste-to-energy facilities operating at MCR (see Chapter V, section C);
- Encourage diversion at the existing public and private transfer stations in the County, by such measures as a revolving low-interest loan fund for purchase of equipment or expansion of facilities, providing markets information and assistance in developing cooperative marketing activities, etc;
- Incorporate the cost of transfer operations and haul when comparing disposal fees at landfills.
- Develop a system of regional transfer stations that will serve the communities in the County to reduce collection truck travel and optimize waste management. Transfer stations in the system should include diversion and rail transfer capability.

H. MARKET DEVELOPMENT

The County continues to place its planning emphasis on the disposal portion of its integrated waste management strategy. The majority of the County's waste management resources are directed toward landfilling. The official policy of the State of California and the County state that 50 percent of the waste stream shall be diverted from landfills by the year 2000. Because diversion is a new approach to solid waste management, the County and the 88 cities should devote a larger portion of the planning effort and resources of the waste management activity to determining just where the diverted materials will go. As discussed in the materials markets trend description in Chapter VII and in Appendix J, recycling, which is the primary form of diversion, takes place only when the material collected by curbside or other programs is used to make a new product. This makes the manufacturers that utilize the recovered materials critical to diversion.

According to a recent report from U.S. EPA,[26] manufacturers that utilize recovered materials in their manufacturing process to make new products also produce economic and environmental benefits, including: creation of manufacturing jobs; creation of sales revenue and economic growth; reduction in air and water pollution; reduced energy and resource consumption; and reduction of the extraction impacts of developing virgin resources. In contrast to the "recyclers", collectors and processors, the manufacturers receive most of the economic benefits of recycling. For example, a ton of old newspaper is worth about $5 collected at the curb, $25 when sorted to specification, and $570 made into new newsprint. The addition of capitol and labor to the recovered materials through the recycling process creates value. Additionally, while jobs are created during the collection and processing of the materials, almost half of the total job creation occurs in the manufacturing phase. The U.S. EPA report uses the example of the processing of 15,000 tons of old newspaper annually; this creates 30 jobs in collection, 40 jobs in processing, and 75 jobs in the manufacture of new newsprint.

Given the economic trends in Los Angeles County, as discussed in Chapter V, the County would be well served by a policy that focused on the development of the manufacturing of new products aspects of the recycling process. The key to this development and the economic benefits it can produce is market demand for the recovered materials. It is a truism that when there is no market for a product, the economic activity associated with the product drops to zero. As discussed in the sections on recovered materials market trends, the industrial sector of the economy has made major investments in the use of recovered materials as feedstocks. There are many things local governments can do to support and assist industry in this. Some examples of specific programs that have been implemented were compiled by the Local Government Commission in the report *Capturing the Local Economic Benefit of Recycling*. .The section of this report, Local Officials Are Playing a Critical Role, is reprinted in Appendix I. They boil down to two recommendations for the County:

- Establish a policy of purchasing and using products that are recovered, reprocessed or made from recovered materials; and

[26]United States Environmental Protection Agency, *Manufacturing From Recyclables: 24 Case Studies of Successful Recycling Enterprises*. No. 530 R95001, February 1995.

- Make industries that add value to secondary materials or use recovered materials in new products a high priority in the County's economic development program.

I. PUBLIC EDUCATION

A County of Los Angeles public education campaign is an essential part of successfully stepping into a proactive role in solid waste reduction/diversion efforts. The County's public education approach would vary by the type of audience. Audiences the County must reach include:

- Residents of the unincorporated areas (for whom the County provides collection services directly or on contract);
- The County public-at-large, including the residents of the 88 cities; and
- The commercial/industrial sector.

1. Residents of County Service Areas

A public information campaign directed to residents of the unincorporated areas that are served by County or County-sponsored collections would primarily convey practical information on "how to" and "why to" participate in source reduction and recycling efforts. The tools available include flyers or brochures distributed along residential collection routes or at central locations such as supermarkets; press releases to local newspapers, advertisers, and community newsletters; presentations to civic organizations; participation or sponsorship of local events; and so on. Spots and programs on radio and television, both commercial and public stations, are very effective. For example, Santa Monica has run extensive programs on waste diversion and disposal. Continual reminders of how and what to recycle are needed to maintain effective residential participation in recycling programs; the information may be developed and distributed by the County or by their contractors under County supervision. Whatever efforts are undertaken to reach this audience must be coordinated with the County-wide campaign discussed below.

2. County-wide Public Information Campaign

Each of the incorporated jurisdictions in the County has developed their own recycling source reduction program, as outlined in their SRREs and implemented by the community. Each will have its own public information component to support the program. However, the County must develop a County-wide Plan that incorporates all of the SRREs (including the SRRE prepared by the County for the unincorporated areas). Preparation of this County-wide Plan is an opportunity for the County to also develop a coordinated public information campaign that enhances the efforts taken by each locality. The County's function in this campaign is that of cheerleader and role model. Highlights might include:

- Develop a model recycling program for all County offices, facilities and operations. Document the development of each type of program, including such factors as waste audits, program planning, costs, employee education, market development, and track program results. Use these "case study" model programs as training materials for private sector recycling/source reduction development projects.
- Develop a County-wide "reduce-recycle" theme advertising campaign.. The campaign theme would then be used for all County public relations efforts and would be made available to local jurisdictions to support their efforts.
- County-wide media campaigns, such as public transit "remember to recycle" posters or broadcast media Public Service Announcement (PSA) spots.
- County-sponsored support programs, such as seminars for local recycling staff, a regional on-line materials exchange, and a County-maintained data bank on regional markets and market prices for recovered materials.
- Development of local media advertisements or public information materials that can be personalized by the local jurisdictions, such as a "home composting" ad or brochure that leaves room for the addition of local contact names, telephone numbers, and addresses.
- A County-wide program targeted to public and private primary and secondary schools that will supplement local school programs, such as a travelling theater show for specific age groups or County-wide art contests.
- Provide continual feed-back on how well this program is doing as is done in other public campaigns.

3. Commercial/Industrial Sectors

County efforts in this area are crucial. The commercial waste stream represents 32.3 percent of the overall waste flow in Los Angeles County; and industrial is 17.0 percent, for a total of 44.4 percent.[7] This fraction includes County government offices, agencies and service providers, as well as private businesses and multi-family housing. Without the cooperation of this broad sector, efforts toward significant reductions in the amount of waste requiring disposal are futile. The business sector has not embraced recycling as wholeheartedly as the public/residential sector (with some prominent exceptions, such as set recycling efforts in the film industry). This attitude on the part of business is understandable as 84 percent of the 212,252 employers in the County are small businesses employing less than 20 people. Small business are more apt to feel they cannot "afford" to recycle and do not understand how it can benefit their bottom line. Larger firms often get caught up in bureaucratic procedures similar to government agencies. The focus of the commercial/industrial/institutional sector is on manufacturing a product and selling it on the market, providing a service and bringing in new customers, or otherwise fulfilling their business aims and goals. However, the message that source reduction and recycling are part of "good business" must be conveyed.

Recommended County Actions:

- Convince businesses that source reduction and recycling, properly implemented, can reduce their operating costs. Make businesses aware of the value of their discards.
- Let the business sector (including County government) know that recycling is appreciated by their customers. Generating customer approval is good business.
- Promote local jurisdiction "waste audits" for businesses, provide technical support.
- Make businesses aware of the liabilities of their discards. Source reduction or elimination of hazardous wastes can pay off in reduced disposal costs.

[7]Totals do not add to 100% due to rounding. *Source Reduction and Recycling Element (SRRE) for Unincorporated Los Angeles County*, County of Los Angeles, Department of Public Works, December 1991. See Appendix G.

Additionally, under the Superfund law, what you threw away yesterday can come back to haunt you in the future.

- Make sure businesses (including County government) understand the consequences of not participating -- State fines (up to $10,000 a day) for not reaching 50 percent diversion impact everyone's taxes; new business and job creation opportunities are lost; and waste transfer and landfill costs will go up.

J. PUBLIC POLICY INITIATIVES

The operative public policy that addresses solid waste management in Los Angeles County is the 1988 Action Plan, which, until superseded, has the force of law in the County. Much has changed in both Los Angeles County and in solid waste management in the last eight years. In fact, AB 939 requires that the County change its public policy to divert solid waste from landfills and document this change in an Integrated Solid Waste Management Plan. This plan has not been published, let alone adopted. In the past, the County has taken a leadership role in solid waste management -- it has provided abundant and cheap landfill capacity. It is time for the County to shift its public policy to the new reality, conservation and diversion, and supply the leadership for this new vision.

There are a number of public policy initiatives that the County could take to supply the leadership that 88 cities cannot supply. The programs that can be implemented to carry out these policies are discussed in the body of this report and its appendices.

Recommended County Actions:

- State that it is the County policy to provide the leadership in conservation of the County's resources and diversion of materials from landfills;
- Lead by example, set and achieve high diversion goals, (above 50 percent) for the unincorporated area and the County facilities;
- Establish variable rate direct billing with itemized cost elements for all generators in the unincorporated area;
- Establish an enterprise fund accounting system for all solid waste management in the County;

- Modify the tax structure in the County to provide incentives to divert materials and meet diversion goals and disincentives for not meeting goals;
- Minimize the landfilling of recyclable materials in County landfills by adoption of landfill bans;
- Declare a moratorium on the approval of new landfill sites in the County;
- Minimize the consumption of existing landfill space;
- Promote the development of facilities necessary to achieve additional diversion, such as composting facilities, MRFs, etc.;
- Establish enforcement that supports diversion;
- Establish requirements on private solid waste management firms that operate in the County to maximize diversion including mandatory recycling, variable rate billing, itemized cost element billing, reporting, etc.;
- Develop reporting and database system that support diversion;
- Develop information and technical assistance programs to support the cities and private industry in source reduction and diversion; and
- Work to establish organizational structures among the cities, Sanitation Districts and the County to coordinate and unify the reduction and diversion efforts.

APPENDIX A

APPENDIX A

PRODUCER RESPONSIBILITY OR TAKE IT ALL BACK

A. BACKGROUND

The basic principle of producer responsibility is that selling a product to someone else does not absolve the seller - manufacturer, wholesaler, or retailer - from the responsibility for the disposal of the product when its useful life is over. This concept has been discussed in Europe and the U. S. since the 1970's. The European Community (EC) began legislated enforcement of the concept with implementation in 1985 of the Liquid Food Containers Directive.

The German Packaging Ordinance was passed by the German Parliament in April 1991, about the time the EC started to work on a directive for all packaging. Two years later, France enacted the Eco-Emballages system and Austria enacted the Alsstoff Recycling Austria. The other EC countries adopted or are working on "take it all back" systems that are similar to the German system (e.g. Belgium), or differ widely (e.g. Britain). All of these systems have to meet the aims of the EC Packaging Directive that was adopted in 1995, i.e.:

- To reduce the overall impact of packaging on the environment; and
- To remove trade barriers and distortions of competition among EC members.

Over the next few years will see an effort to reconcile the national programs that are in place with the EC Packaging Directive. This will take considerable political energy. In the meantime, additional "take it all back" directives are being developed for batteries, electronic products and automobiles.

B. THE GERMAN SYSTEM

The German Packaging Ordinance has had a significant impact on that nation's packaging manufacturers, distributors, retailers, and consumer products industries. Industry has the

obligation to take back used packaging and ensure it is reused or recycled. This obligation applies to all packaging. The goal of the regulation is to reduce packaging waste by six to eight million metric tons annually, or 20 to 25 percent of the residential waste stream. Packaging currently accounts for half the volume and one-third the weight of Germany's residential waste stream.

The Ordinance is markedly different from the many North American attempts to control packaging in that it assigns the private sector the responsibility for reducing waste. The German Environment Ministry is adamant that suppliers of a product, not municipal governments, are obligated to take back product packaging.

The implementation of the Ordinance was divided into three phases; each phase focused on a different type of packaging.

The first phase of the Ordinance addressed transport packaging (mostly corrugated cardboard, but also barrels, canisters, cases, sacks, pallets, polystyrene, and shrink wrap) and went into effect December 1, 1991. It required that the 2.3 million metric tons of transport packaging used to deliver goods to retailers be returned for reuse or recycling.

The second phase addressed secondary or distribution packaging -- basically, packaging designed to get the product to the store and promotion packaging, including cartons, canisters, trays, and plastic bags -- and went into effect April 1, 1992. At that time, consumers were permitted to leave secondary packaging in stores.

The third, final, and most controversial and widely publicized phase addressed primary packaging -- i.e. the immediate covering for a product, such as bottles for wine, cans for coffee (sealed with plastic), cans, jars (for mayonnaise, mustard, caviar), aseptic boxes, blister packs, and tubes for tooth paste, etc. -- and went into effect January 1, 1993. Retailers were required to either provide facilities to take back waste packaging or to participate in a privately funded collection system that guarantees minimum recycling rates for specific packaging materials. If those rates were not achieved, the government threatened to impose deposits on a variety of

packaging types. Germans already buy 72 percent of their beverages in refillable glass and plastic containers that carry deposits of from 30 to 70 pfennings (US 18 to 42 cents). The packaging ordinance stipulates that the market share of refillable containers must not fall. By July 1, 1995, the Ordinance had been modified to require that 80 percent of each type of packaging material must be collected. Also, that least 80 percent of each material collected must be separately sorted for recycling.

Reluctant to become repositories for the country's discarded packaging, German retailers, along with 600 packaging firms, consumer products companies, and raw material suppliers, formed a company, Duales System Deutschland (DSD), that created a dual (hence, "Duales") system that was to be separate and distinct from existing municipal garbage collection services. DSD, a Bonn based enterprise, began initial implementation in July 1991, with pilot collection programs in selected regions -- including seven cities. By March, 1992, DSD had signed contracts in 138 regions of the country, serving 21 million people or 25 percent of the population. A goal was to serve 90 percent of German's 80 million people by 1993 was set and a nationwide system of drop-off facilities and collection programs for eligible packaging waste was established.

The DSD system was initially intended to completely replace municipal collection of packaging materials. That, however, led to accusations of DSD creating an illegal monopoly. Thus, its collection strategy was changed to encourage cooperative relationships between it and municipal haulers. Collection for the DSD is now provided by public or private haulers under a contractual agreement with DSD, with each community having a slightly different contractual arrangement, based on existing collection and recycling programs.

The basic DSD concept is to collect glass (sorted by color) and mixed paper at drop-off centers using "igloos." While igloos had been distributed in most regions of the country prior to DSD's existence, more containers since been strategically placed to serve about 500 residents per site. All other packaging materials are collected at curbside in yellow bins. It has been estimated that the implementation of this waste system will ultimately require about 200 sorting and processing facilities because of the increased volume of recyclable materials. The cost of

implementing the DSD system was originally estimated at 7 billion Marks (US $4.2 billion), with annual operating costs of 2 billion Marks (US $1.2 billion). DSD's operating costs for 1994 were about DM 3.3 billion, and costs in 1995 were forecast to be around DM 3.9 billion. Both are well above the original estimates. By 1995, the total network provided an estimated 18,000 jobs.

The DSD raises the revenue to pay for the facilities through the "green dot" system. Under this system, participating companies pay a licensing fee that varies according to the size and material of the package. With these licensing fees, the consumer products companies obtain the right to display the green dot on their packaging. Packages displaying the green dot are guaranteed a market by materials processors and, thus, effectively come with the warranty that they will be recycled. By April, 1992, DSD had sold 5,000 licenses to hundreds of domestic and foreign based companies. By 1995, this number had grown to more than 17,000. Because most of Germany's large retailers have threatened to provide shelf space only to those products carrying the green dot, DSD estimates that 80 percent of all packaging will have the symbol by the end of this year.

Companies using plastic and certain types of aluminum packaging must, prior to using the green dot, obtain additional take-back guarantees from trade associations. Because plastics are the most expensive material to collect and recycle, licensing fees for them are 25 percent higher than for other types of packaging and will soon increase by at least 50 percent. The average is two pfennings (a little more than a US penny) per container. Average consumer prices will rise by half a percent because the additional cost of this green dot licensing will be passed on to consumers. The DSD will thus cost an estimated $120 per household per year, and raise about $1.2 billion annually. Much of this DSD revenue will be spent on a multi-media campaign to educate consumers.

Consumer reaction has been positive to the option of being able to return packaging waste.

C. RESULTS OF GREEN DOT PROGRAM (DSD) TO DATE

The DSD program seems to be a success in terms of the German Packaging Ordinance's original goals. A recent study by a large German retailer concluded that secondary packaging in grocery stores has been reduced by up to 98 percent, or 51,000 metric tons annually. A random survey of 400 DSD members determined that 199 types of packaging materials (26 percent) had recently been entirely eliminated and that a quarter of all products they handle no longer come with any packaging. Of the 146 members that had formerly used plastic blister packs, only one still does. Polyvinyl chloride packaging, which had previously been used by 57 members, has been universally eliminated. Plastic foams also were abandoned after previously being used by 35 respondents. Paper and cardboard often are substituted for packaging that is difficult to recycle. A quarter of packaging materials used by respondents now contains recycled materials.

The DSD system, however, is very expensive and almost went bankrupt. The reasons for its financial difficulties are:

- The emphasis in on materials recovery with very high recycling targets - DSD has to insure that 64 % of the plastic packaging is recycled;
- Short implementation time - 18 months for the countrywide system;
- DSD is responsible for all collection and sorting costs and re-processors receive the material for free;
- DSD concluded unfavorable contracts due to the time constraints and, thus, its weak bargaining position; and
- Firms used the green dot label and did not pay or were late in paying their fees.

In the last year or so DSD has addressed these issues. Contracts have been renegotiated and controls on the use of the green dot tightened up. Also, starting in January 1996, re-processors have been paying the market price for materials.

The DSD system, with its green dot recycling guarantee, provides a financial incentive for industry to design packaging which is easily recyclable. However, it still has been widely criticized. Environmentalists and some politicians view it as an easy way out of more expensive requirements involving deposits and take back requirements for retailers. Other critics contend that the fees for the DSD system are not high enough to eliminate much of the throw-away packaging and that, despite the green dot, some materials, such as plastics, remain too difficult to recycle. Proponents of the DSD system counter that because packaging that is more difficult to recycle will incur higher processing costs, the system provides a built-in incentive for manufacturers to use materials which are easily recycled. They also assert that because the green dot licensing fee is based on the size of the package, it provides a reason for firms to use smaller packaging.

Additionally, DSD's educational campaign has been attacked for appearing to suggest that products bearing the green dot are environmentally friendly.

And, the rapid implementation of the DSD collection system has been blamed for putting large quantities of recovered materials on markets that were not capable of absorbing them. This has caused, it is claimed, the prices paid for these materials to drop and thereby jeopardize the entire recycling effort. While it is true that recovered materials prices have dropped in Europe and worldwide in the past year, it is highly unlikely that this is solely due to the DSD system implementation.

There is a perceived threat to the current prevalent system of returnable bottles, which is seen in Germany as one of the most effective ways to eliminate packaging waste. Such refillable containers would not be part of the DSD system and would not bear the green dot, and hence may be viewed as not being environmentally sound. To address the danger, the Ordinance stipulated that the market share of refillable containers must not drop below the current 72 percent for beer, water, soft drinks, juice and wine, or 17 percent for milk. If the market share goes below those levels, the exemption from mandatory deposits on all beverage containers will not apply. Many environmentalists are not satisfied with those quotas, contending that they preserve the status quo and do nothing to increase the use of returnable containers. Further,

because the returnable bottles favor local bottling and short transportation links, the EC may decide that this approaches a device to restrain trade. This could result in a major political battle.

APPENDIX B

APPENDIX B: DIVERSION ALTERNATIVES

In this Appendix, various technologies and management techniques for solid waste that have been applied in other U.S. communities are discussed. Frequently, examples of community experiences are provided along with a description of the approach to illustrate what practically can be accomplished (as opposed to theoretical diversion estimates). For some technologies, where sufficient operating experience across many facilities is available (such as waste-to-energy) specific examples are not needed.

A. SOURCE REDUCTION

Reduction at the source is the first of California's hierarchy of integrated waste management practices. Defined in AB 939 as "any action which causes a net reduction of solid waste" source reduction represents a proactive, front-end approach to waste diversion. In the SRRE* the County estimates that it will achieve a 4.3 percent diversion of the total waste stream by 2000 through source reduction. The Cities have similar goals. Section 18734.3 of the regulations lists a minimum source reduction alternatives in four categories:

1. Rate structure modifications;
2. Economic incentives;
3. Technical assistance and promotion; and
4. Regulatory programs.

Of these the County rated Rate Structure Modifications the most effective. Within each of the categories there are a number of specific programs that the County and the Cities could adopt and promote. The objective is to get the individual waste generators including the County and the Cities to reduce their waste generation. Seven strategies that waste generators should apply are:

1. Purchase products for recyclability and reduce the use of non-recyclable materials;
2. Reduce packaging and reduce the toxicity of packaging and products;
3. Increase the amount of recycled materials in packaging and products;
4. Replace disposable products with reusable products and products made with recycled materials;
5. Use materials and products more efficiently, i.e. print on both sides of paper;
6. Purchase products with longer useful lives, i.e. 60,000 mile tires, and products designed to be repairable; and
7. Reduce yard waste by on-site management, i.e. "grasscycling".

The key to source reduction is modifying individual behavior. Policies, programs, and incentives that support source reduction goals have been implemented in the communities that are most successful in diverting waste from landfills. These alternatives work synergistically with recycling programs to maximize diversion. This can be seen in the Seattle, Washington case study discussed in Appendix D.

The sections below focus on two types solid waste management approaches that can be used to increase diversion: collection techniques and processing technologies. The collection techniques discussed in Section A are applicable to diverting many types of materials, and bring them into the processing facilities. The processing facilities discussed in Section B can also be applied to different waste stream materials. In order to avoid "double counting" waste stream material diversion achievable by application of these processing technologies, specific materials are discussed separately under each technology heading. These technologies have been applied to divert the Los Angeles waste stream in Chapter VII.

B. COLLECTION

The techniques used to collect MSW have an impact on the diversion potential. Once recyclable materials are mixed in with materials that are potential contaminants, they are harder

to recover. For example, when food waste from a supermarket is placed in the same container as old corrugated containers (OCC), then collected in the same truck, the OCC is contaminated by the food and is less recyclable. The food-contaminated OCC is unacceptable as feedstock to a paperboard manufacturing plant, but could be composted to a lower-value humus product.

The general approach is to identify specific materials in the residential, commercial and industrial waste streams that contain recyclable materials or that should be collected separately to maximize recycling and diversion. Optimization of collection systems and routes has a large economic return for both the public and private sectors because collection generally consumes about two-thirds of every solid waste management dollar (see Appendix E).

Techniques that have potential to increase diversion and improve the quality of recovered materials include the following:

1. Intensive Residential Curbside Collection

This approach adds residential mixed paper (junk mail, OCC, boxboard, phone books, kraft bags, and magazines and catalogues) and textiles to the standard set out and collection. Separate set out and collection of yard waste, if not used, should be added. This alternative may be coupled with new collection techniques such as the split container and truck system used in Visalia, California; or the once per month collection of recyclables used in Seattle, Washington. Based on a survey of 19 California programs[1] the average household set out 189 pounds of mixed paper (excluding newspaper) in 1994. Based upon the addition of mixed paper to County-wide recycling collection to 2,989,552 households, the additional diversion at this rate would be an estimated 283,000 tons. Seattle, Washington averages over 100 pounds per family higher in residential mixed paper collection than the 19 California programs. If an intensive program such as Seattle's was implemented County-wide, an estimated 383,000 tons per year could be diverted. This is only 10 percent of the estimated total paper disposed of in the County in 1994.

[1] *Resource Recycling*, June 1995.

Table C-1. Recovered Paper Volumes from Selected Curbside Recycling Collection Programs
(Pounds per Household per Year)

Program	Households	Paper Fraction[1]	ONP	RMP	OMG	OTD	OCC	Total
Barrie, ON	27,000	59%	169	16[2]	[3]	[3]	44	229

ONP – newspaper
RMP – residential mixed pper
OMG – magazines
OTD – telephone directories
OCC – corrugated cardboard

[1] Of total volume of recyclables collected by curbside recycling collection programs.
[2] Includes only OCC; household fine paper is collected with ONP.
[3] Collected with ONP, shown in Total Column.
[4] Summary of 19 programs that range in size from 10,000 to 275,000 households.
[5] Processed with residential mixed paper.
[6] Small pieces of OCC accepted with RMP; large OCC is not accepted.

Source: *Resource Recycling*, June 1995.

Table C-1 shows mixed paper recovery from programs in 12 cities. The mixed paper is broken into its components: (1) newspaper - ONP, (2) residential mixed paper - OMP, (3) magazines - OMG, (4) telephone directories - OTD, and (5) old corrugated containers - OCC. The cities vary in size and results; however, all show a significant increase in paper recovery over newspaper alone. In 1994, Ecodata, Inc. conducted a survey of 60 randomly selected cities with curbside programs.[2] The diversion rate for the curbside programs averaged 13.4 percent, with a range of 3 percent to 34 percent. Eight cities were identified as high achievers with 20 percent or more diversion: Daytona Beach, Florida; Elmhurst, Illinois; Hoffman Estates, Illinois; North Las Vegas, Nevada; Paramus, New Jersey; Port Huron, Michigan; Stamford, Connecticut; and Valley Stream, New York. Five of the eight cities collect mixed paper at the curbside.

A number of communities have added textiles to their curbside collection programs. These include: Bloomfield, Connecticut; Windsor, Connecticut; and Ann Arbor, Michigan. In October 1994, St. Paul, Minnesota expanded an existing pilot program that collects textiles and reusable items to a city-wide service. These materials have accounted for 1.8 percent of St. Paul's curbside collection.[3]

2. Wet-Dry Collection

Wet/dry collection originated in Europe. The system has the waste generator separate waste into either two or three categories and use two or three bins. The two-bin system is a wet/dry separation. The two streams are collected separately and are processed by different systems. Dry materials are processed at a materials recovery facility (MRF) and the wet fraction is composted. The three-bin system adds a residue bin that is collected separately for disposal. Wet/dry collection has application in both residential and commercial sectors. Applied to the residential sector, recovery well above the 50 percent level has been demonstrated. Santa Barbara County[4] conducted a pilot program with several different collection schemes: both two-bin and three-bin systems. The diversion rates ranged between 57 and 73 percent, with an average of 65 percent. The project recognized that high rainfall had increased yard waste; adjusting for this factor, the average diversion in the Santa Barbara pilot program was 58 percent. A number of communities in Canada and the United States have implemented full-scale wet/dry programs. These include: the City of Guelph and the City of St. Thomas, Ontario; Mackinac Island, Michigan; and East Hampton, New York.

Other communities are separating selected organic waste fractions for collection and processing. These programs target food waste from restaurants, supermarkets and food processing companies for composting. Some programs also include soiled paper, paper mill sludge and other organic materials in the composting mix. Commercial collection of food waste from restaurants, supermarkets and other food service establishments that are collected on a single route could be delivered to a composting facility. The non-food waste from other commercial establishments such as offices then would be free of food contamination and more easily recovered. For example, waste from some office buildings contains 90 percent paper. Without the addition of other materials during collection, waste paper from offices is highly recoverable. There are many examples of high level commercial/industrial waste diversion, ranging from 60 to 90 percent. These include major U.S. and California firms, such as AT&T, IBM, Fetzer Vineyards and Transamerica Corporation.

Separate collection of food waste is a rapidly expanding technique. Programs have been implemented in Freehold, New Jersey; Calgary, Alberta; Jasper National Park, Alberta; and Burlington, Vermont. A number of food market chains are interested in the approach and have initiated programs including Shop-Rite in five states, Safeway in Ontario, and Stew Leonard's in Connecticut. In California, Vons has implemented a program with Community Recycling and Resource Recovery, Inc. This program manages food waste from all 325 Vons stores. The food waste collected in this program is composted at CRRRI's facility in Lamont, California.

[2] *Resource Recycling*, October 1995.

[3] *Resource Recycling*, April 1995.

[4] *The Santa Barbara County Pilot Waste Collection Project*, Final Report, April 1994.

3. Construction Waste

During construction projects, the general contractor usually provides a roll-off box that is used for waste from all subcontractors on the site. The materials in the roll-off are mixed as a result. If subcontractors had to remove their own waste, or if the general contractor provided separate containers, then lumber from the carpenters, gypsum from the drywall contractor, asphalt shingles from the roofer, and other specialized materials from individual trades would be separately collected and would be recyclable. This is currently being done by Cornerstone Material Recovery, a private firm in the Chicago, Illinois metropolitan area and is expanding to other cities in the United States.[5]

4. Comprehensive Drop-off Centers

To augment other collection alternatives, a system of centers designed to accept all types of waste and recyclable materials will divert additional material. Some of these drop-off facilities accept reusable items such as building materials and furniture, household hazardous waste (e.g., paint, batteries, household cleaners), used oil, auto parts, appliances, yard waste and refuse. Urban Ore in Berkeley, California is an example of a usable material drop-off; it has been operating since the early 1970s. Champion Paper, Inc. has established a system of 1,000 drop-off centers in Houston, Texas. Champion operates these centers under a 20-year contract to collect paper for their Houston plant.

At a drop-off facility, reusable and recyclable items could be accepted at no charge, while refuse requiring disposal could carry a small charge. Fairfax County, Virginia operates a large multi-material drop-off adjacent to its transfer station. The Fairfax facility accepts all the regular recyclable materials, yard waste, white goods, used oil, and wood; all of which are recycled. In addition, conveyors are provided to accept bagged waste and a conveyor transfer system for bulky non-recyclable materials. The facility is staffed to assess fees for larger loads from residents and small commercial operators.

[5] *Biocycle* Magazine, Pages 62-63, August 1992.

C. PROCESSING FOR DIVERSION

1. Materials Recovery Facilities (MRFs)

Material recovery facilities (MRFs) are designed and built to process a variety of solid waste streams. These include: (1) source separated materials from curbside collection or drop-offs, (2) commercial waste with high levels of recyclable materials such as office paper, (3) the dry stream from a wet/dry collection, (4) selected construction and/or demolition (C&D) waste, and (5) mixed municipal solid waste. The source-separated materials facilities are most commonly known as MRFs, commercial mixed waste facilities are often referred to as "dusty MRFs," and C&D or mixed MSW facilities are called "dirty MRFs."

The objective of all MRFs is to recover materials from the waste stream by separating them into marketable commodities. For example, glass is separated from other containers and contaminants, then sorted by color (amber, green and clear). The product is a clean, color-sorted glass that meets the glass manufacturing industry's specifications for glass cullet used to manufacture new glass products. The processes used by a MRF to accomplish these separations can be low-tech (relying primarily on hand-sorting) or high-tech (utilizing mechanical equipment as well as hand-sorting as needed). The materials processed and marketed by MRFs depend on the MRF feedstock.

Source-separated materials MRFs generally include all types of containers (glass, aluminum, steel and plastics); plus various types and grades of paper including newsprint, office paper, mixed paper, corrugated cardboard, etc. In the source-separated MRF, usually only PET and HDPE plastic containers are sorted, although other resins may be recovered. Technology now exists to mechanically separate plastic containers by resin and color; the identification of these are made using a variety of sensors employing x-ray, infra-red and other electromagnetic spectra. The prototype of this machinery is installed in Salem, Oregon and operates at 1,250 pounds per hour. Development of the prototype resulted from Oregon's legislation requiring that all rigid containers be refilled, be recycled or contain recycled material. This is an example of policy driving technology development and implementation.

A national survey of MRFs completed at the end of 1995 identifies and describes 386 facilities, 90 percent of which were in operation or under construction at the time of the survey.[6] No transfer stations with "dump and pick" operations are included in the current MRF list, an indication of the maturity of the MRF technology.

MRFs have the potential to process and market a significant portion of the solid waste stream in Los Angeles County. Even though there are an estimated 200 facilities which do some processing presently operating in Los Angeles County, additional facilities will be needed. MRF processing is an integral part of the strategy recommended for Los Angeles County to implement a diversion-oriented policy that achieves or exceeds the 50 percent goal. The diversion projections discussed in Chapter VII are predicated on the following assumptions:

- Intensive residential curbside collection is instituted County-wide
- Curbside collection is provided to single-family households in the County except those rural areas where population densities do not warrant it;
- Curbside collection is supplemented by a system of comprehensive drop-off facilities, particularly in rural areas not served by curbside collection, and multi-family dwellings;
- Private haulers are mandated to provide recyclable material collection to their contract accounts (businesses, industries, institutions);
- High participation rates for all forms of diversion collection are achieved by high levels of public information and enforcement of mandatory requirements;
- Materials processed by MRFs include: glass, steel and aluminum food and beverage containers; HDPE and PET plastic containers; all clean paper (newsprint, magazines, corrugated cardboard, mixed paper); and textiles;
- Potential contaminants such as food waste are collected and processed separately from commercial/industrial waste;
- MRF residue (non-processible material sent for disposal after processing) is 15 percent; and
- Commercial/industrial wastes are processed in a MRF prior to disposal.

[6] *The Materials Recycling and Processing Industry in the United States*, Eileen Brettler Berenyi, Governmental Advisory Associates, Inc., 1995.

2. Composting Facilities

Composting is defined as the bacterial decomposition of organic materials. All of the composting technologies commercially available today rely on aerobic decomposition (that is, utilizing bacteria that live in the presence of oxygen). Anaerobic digestion of waste stream materials (composting that utilizes organisms existing in an oxygen-free environment) is still in development and is not considered further in this report. Composting reduces the quantity of incoming organic material by about 50 percent by weight, through the loss of moisture and production of carbon dioxide during the decomposition process. When non-digestable materials such as metals, plastics and glass are present in the feedstock, a residue will result. The quantity of residue depends on the quantity of non-compostable material in the feedstock.

During the composting process, high temperatures generated by bacterial activity serve to kill pathogens as well as most seeds and spores. Processing can be relatively low-tech, such as windrow piles that are turned occasionally to maintain proper moisture and temperature for bacterial activity, to high-tech, totally enclosed and mechanized reactors that have been applied to a variety of waste feedstocks. All of the technologies discussed below are focused on processing quantities diverted from the waste stream, as opposed to home composting approaches. Home composting can divert residential yard and food wastes (except meat and dairy wastes). Composting, by its nature, produces odors which must be controlled.

Markets for compost derived from components of the MSW stream are still developing. Composting is used to convert organic material into a usable soil amendment. Compost can be used as mulch, or can amend clay or sandy soils to improve moisture retention and friability. The market for this material is the same as the market for peat moss, including farmers, home gardeners, landscapers, nurseries, potting soil manufacturers, etc. The industries and farms that can utilize these materials in significant amounts are tentative about risking their livelihood on a relatively unfamiliar product. Considerable education efforts, demonstration programs, and scientific studies are still needed to open these markets to the very large amount of materials composting is expected to divert from the waste stream.

a. Yard Waste

Yard waste materials are the most common compost feedstock. All yard waste materials (also called "green waste") must be diverted from disposal in California. Many of the Cities in Los Angeles County collect yard waste separately. In the City of Los Angeles, yard trimmings from the curbside collection program are used by San Joaquin Composting (SJC) as bulking agents for composting the City's biosolids (see below) at SJC's facility in Lost Hills, California. This City program is known as Full Cycle Recycle (FCR). FCR presently diverts all biosolids generated by the City of Los Angeles, and all yard trimmings collected at curbside. As of the beginning of 1995, about 250 tons per day were delivered to SJC, and the remaining material was either composted elsewhere or used as mulch. As the curbside collection program continues to expand, all future yard trimmings collections will be incorporated into the FCR program, thus diverting all residential yard waste generated in the City from disposal. The FCR plan calls for the creation of local facilities that will play a major role by serving as yard trimming drop-off and transfer to SJC sites, and, after processing, centers for bagging and distributing the product, "TOPGRO." TOPGRO is presently bagged at the Lost Hills facility and marketed by an SJC subsidiary, Organix Supply, Inc. TOPGRO is sold by local outlets, such as Fedco membership department stores and Armstrongs' -- The Home and Garden Place. The compost is also used by City agencies in maintaining City-owned parks, gardens, and golf courses, and for facility landscaping.[7]

The green waste fraction of yard wastes (i.e., leaves, grass clippings, weeds, small prunings) can be composted alone or in conjunction with other waste materials, such as biosolids, food wastes, contaminated paper that otherwise cannot be recovered (such as disposable diapers), and similar organic fractions of the waste stream. An estimated 100 compost facilities were in operation in California as of May 1995.

Yard waste is also diverted from disposal through source reduction approaches, specifically, the "don't bag it" method of leaving grass clippings on the lawn to provide nutrients

[7] "Co-Composting in Los Angeles Optimizes Resource Management," *BioCycle*, December 1994.

and reduce waste, and home composting. In Alameda County, California's Master Composter program has trained 39 Master Composters, who, in turn, have trained over 5,000 home composters in the County. In 1993, 6,600 home compost bins were sold by the County program to homeowners. A follow-up survey showed 94 percent of the recipients regularly used their bins. Previous survey work in Alameda County demonstrated that each home compost bin diverts approximately 600 pounds of compostables each year. Based on the participation rates, the County estimates that the 1993 bins divert 1,800 tons from the County waste stream. San Diego County has established a Master Composter demonstration center at Quail Botanical Gardens. The Master Composters trained at the Center commit to 40 hours for teaching the knowledge and skills they have gained to others.[8]

In addition to use as a bulking agent for composting, woody waste (i.e., tree limbs, branches, brush) can be chipped and used as mulch or wood fuel (as discussed above). The Public Utilities Commission's deregulation of the electric utility industry caused a number of wood-waste-to-energy plants to close in California; as a result, the fuel market for wood chips is limited at the moment. Because of a medfly quarantine in Southern California, all yard trimmings have to be processed within the quarantined area before they can be transported elsewhere. Chipping and composting interfere with medfly reproduction.

Yard wastes lend themselves to low-tech composting operations, because the low nitrogen content means relatively low potential for odors during the composting process. Some materials, such as grass clippings, are high-nitrogen and must be handled more carefully to manage odor. Larger facilities may roof over the composting area, the pads may be paved, and some facilities enclose the initial composting area to avoid operational problems, such as excessive moisture from precipitation, over-drying from winds, or materials blowing off-site. Each "improvement" to the system adds to the overall cost.

In January 1995, the California Integrated Waste Management Board (IWMB) issued a ruling that shredded yard waste could be used as alternative daily cover on landfills and that this

[8] "Mastering the Way to Home Composting," *BioCycle*, January 1994.

use would count toward achievement of the 50 percent diversion goal. This reduces the incentives to develop markets for compost and mulch and consumes landfill capacity. The Natural Resources Defense Council (NRDC) initiated a lawsuit against the IWMB. The NRDC contended that this practice is not recycling or diversion, but landfilling. In February 1996, the Sacramento County Superior Court ruled against the IWMB. IWMB has appealed.

California Futures/Global Futures estimates that less than two percent of the potential agricultural demand of 10.6 million tons of compost per year is utilized.[9] Policies in the State and County should provide incentives to meet this potential demand.

b. Food Waste

Composting of food wastes is more problematic than yard waste, because of the potential for generating odors and attracting birds, rodents, and insects. Consequently, food waste composting is generally carried out in enclosed vessels (in-vessel or static-pile systems) during the first stages of decomposition. The later stages of decomposition can be carried out in windrow-type operations that are used for yard wastes. As discussed previously, a number of food waste composting project are operating in the U.S. These include school programs in New Hampshire, Freehold, NJ, Calgary Alberta, Minneapolis-St. Paul, MN, and the Von grocery stores project in Southern California.

It should be noted that food waste is collected, cooked, and used as hog and other animal feed in some parts of the country. In Florida, Walt Disney World has been sending five tons per day of food waste to Kenny Camp Farms since 19092. Two companies are actively marketing processing equipment to make feed pellets from food waste. However, markets are not readily available in Los Angeles County.

The product resulting from food waste composting is higher in valuable nutrients than yard waste compost. The product can be utilized as a fertilizer in addition to its soil amendment

[9]California Futures/Global Futures, *Agricultural Markets for Compost and Mulch: Costs, Benefits and Policy Recommendations*, December 1993.

properties. Because of the higher nutrient content, food waste compost has a higher market value.

c. Biosolids

Biosolids are also referred to as sewage sludge; this material is the solids portion resulting from wastewater treatment. Properly conducted composting processes reduce the pathogen contents to safe levels. The U.S. EPA has published regulations concerning composting (and landspreading) of biosolids (Clean Water Act, Part 503). The Part 503 requirements specify both the process parameters (time, temperature, moisture, etc.) and application limits depending on the product quality.

Because of the high moisture content of the biosolids entering the compost process (usually biosolids have been dewatered but are still 50 to 80 percent water) and the potential for odors, biosolids composting is initially conducted in enclosed vessels. The nearly-completed compost can mature in windrow piles.

Biosolids compost is, if made from uncontaminated feedstocks, a high quality soil amendment and, if properly marketed, will sell easily. In 1994 there were 201 operating biosolids composting facilities in the U.S. and another 117 under development.[10] Of the total 318, a number of commercial biosolids compost products are successfully marketed, including Philadelphia's EarthGro and the Maryland Environment Service's COMPRO, which sells in bulk to developers for $17 per ton and is bagged for consumer sales.

The City of Los Angeles' Full Cycle Recycle program provides feedstock to the TOPGRO manufacturer, as discussed earlier. In addition, Wheelabrator (Biogro) has proposed a facility with capacity for 500 TPD biosolids and 1,000 TPD other organics. This facility is planned for the Antelope Valley.

[10] 1994 Biocycle Biosolids Survey, *BioCycle*, December 1994.

d. Combination Feedstocks (including manure)

The example of a combined feedstock approach is being implemented at the Zoo in Griffith Park. The Griffith Park Composting Project, undertaken by the City of Los Angeles Biosolids Management Division with the Departments of Public Works and Recreation and Parks, will compost Zoo manure with biosolids and green trimmings from the park. If the current demonstration project is successful, a permanent facility will be built. The compost will be sold as a specialty product under the TOPGRO label.[11]

Combining feedstocks requires the compost processor to tailor the facility design, operations and equipment to the needs of the more problematic materials, such as manure. Enclosed buildings, compost vessels, and process air cleaning equipment (to reduce odor emissions) are all needed to reduce environmental impacts of these facilities. Combining feedstocks, however, allows the operator to "design" the end product to meet the specifications of a particular market, including balancing nutrient content, moisture, degree of stabilization, and particle size.

e. Mixed MSW

There were 17 mixed MSW composting facilities operating in the U.S. as of January 1995.[12] However, mixed waste composting is still in the development stage. Most facilities operate at a small scale in order to allow strict control of the waste entering the system. The largest facility in that list that is still operating is the Bedminster BioConversion system in Sevier County, TN. This plant started operation in 1992 and will process 200 TPD when the current expansion is complete. The systems used are high-tech, and in most approaches, the waste must be pre-processed to remove potential contaminants (glass, plastics and other inerts, and items with toxic components such as batteries) so that the resultant compost is low in chemical contaminants.

[11] Reba Fabrikant and Ray Kearney, "CoComposting in Los Angeles Optimizes Resource Management," *Biocycle*, December 1994.

[12] *Municipal Solid Waste Composting: A Status Report*, prepared by GBB for the Solid Waste Association of North America (SWANA), April 1995.

The markets for compost made from mixed MSW have so far been limited. The mixed waste composting process can result in a product that meets the EPA's Part 503 standards for biosolids compost; however, of the 17 operating facilities only one is successfully doing so. Both product quality and market development is needed. It should be noted that the Sevier County, Tennessee facility, which accepts 150 TPD of solid waste and some biosolids, has been successfully marketing its product to agricultural and horticultural users since 1992.

The amount of materials that can be diverted by composting programs differs by feedstocks. Assumptions used in calculating composting diversion are:

- The County bans disposal of all green waste, resulting in 95 percent of this material diverted from disposal. Most will be composted; woody waste will be chipped and used as mulch or as a bulking agent for biosolids composting.
- Food waste is not readily separated and collected from residences, because the material must be collected daily to avoid odor problems. Therefore, the target group for food waste composting would be large producers, such as canneries or other food processors, restaurants, and institutions. The target group is part of the commercial waste stream, where food waste is approximately 13 percent of the waste. Eighty percent of this is projected to be separately collected and composted.
- No biosolids should be landfilled in LA County. The current composting efforts should be expanded to provide capacity for all biosolids produced by wastewater treatment plants. Composting can be supplemented by landspreading programs in some areas of the County.
- Special projects are developed for unique feedstocks (such as LA City's Zoo manure project). These waste streams are too small to impact diversion rates County-wide.
- Mixed MSW composting projects are envisioned as part of Level 3, as discussed in Chapter VII, for residential waste not collected separately.
- Compost markets need to be developed to accommodate the feedstocks listed above before any further compost products could be considered.

4. Construction And Demolition Waste Facilities

With construction and demolition (C&D) materials amounting to as much as 30 percent of municipal solid waste, diversion through C&D recovery operations conserves large amounts of landfill space and adds years of useful life to landfill facilities. The City of Los Angeles calculates that nearly 15 percent of the solid waste stream is construction and demolition (C&D) materials. In some Southern California jurisdictions, C&D materials represent almost half of the total waste stream.[13] C&D materials generation is dependent on economic activity in the construction and building fields. Also, natural disasters can significantly increase the amount of C&D material in the waste stream.

The three basic categories of recoverable materials within C&D are inert materials, shredded wood products, and ferrous metal. Recovered inert materials, such as asphalt, concrete, dirt, rock and brick, are used for land reclamation, landfill final cover, fill for roads and airports, embankments, road base and subbase, aggregate for filter layers in landfills, French drains and bridge abutments, and asphaltic concrete. Uses for shredded wood include landfill cover, boiler fuel, animal bedding, composting bulking medium, pulp mill feedstock, and raw material for particle board. Recovered ferrous metals are used in remanufactured steel.

There are two basic types of facilities that process C&D materials. The first type accepts only clean loads of a single material such as concrete, asphalt, or wood. Processing usually includes size reduction with a hammermill or shredder, followed by sizing through a trommel screen or vibrating deck screen. Some manual sorting may be required to ensure the highest possible quality in the end product.

The second type of facility processes mixed C&D material. The material is brought to a tipping area, usually in a dump truck or roll-off box. Large pieces of materials, such as concrete, wood and metal, are pulled from the pile for processing. The remaining materials are fed into a mechanical processing system.

[13] *Business Recycling and Waste Reduction Guide*, The County of San Bernardino Solid Waste Management Department and The Cities of San Bernardino County.

The steps and equipment involved in mechanical separation and size reduction of C&D waste are generally very similar. Because many systems contain mobile equipment, the configuration of the machinery may be revised as characteristics of the feed and products change. Processing systems typically use trommel, disc or vibrating flat-bed screens to separate rock and soil. Density separation (e.g., pneumatic or hydraulic sink/float operations) is then used to divert wood scrap from heavier fractions. After wood scrap is size reduced though a hammermill or grinder, the material is often subjected to magnetic separation to remove the metal fraction.

Depending on the incoming waste stream, C&D processing facilities can range in size from under 50 tons per day to well over 2,500 tons per day. Cyclean, Inc., an asphalt recovery plant in Los Angeles, has kept over a million tons of asphalt out of the landfill in the last seven years and has saved the City $10 million.[14] Cyclean uses a microwave technology to make hot mix from 100 percent recycled asphalt. In addition to old pavement, crumb rubber from old tires can easily be incorporated into the Cyclean asphalt. The Cyclean product is sold at a discounted rate to the City of Los Angeles.

Pallets and dimension lumber are also reusable. A survey completed by *Pallet Profile Weekly* in December 1993 revealed that 70 percent of all pallets received for recycling are repaired for resale. Only one percent of the pallets are disposed in landfills.[15] The remainder of the pallets are dismantled for repair supplies, or ground into chips for use as boiler fuel, mulch, animal bedding, or particle board furnish. Guadalupe Landfill, in San Jose, California, has taken an innovative approach to managing the high percentage of redwood materials it receives from demolition projects. New World Furniture, an affiliated company, separates and reprocesses the redwood material, then an on-site carpenter re-works the wood to create home and garden items. The company grinds the unsuitable material to a 2-inch minus size, and markets this redwood mulch through Valley's Pride Organics, a Guadalupe Landfill division. In Portland, Oregon, the number of wood processing facilities jumped from three to eleven in

[14] "Paving with Recycled Asphalt," *BioCycle*, September 1994.

[15] Roger Guttentag, "Making Recovery Pallet-able," *Resource Recycling*, November 1994.

1990. Currently, recycling facilities in the area handle 100,000 tons of wood each year.[16] Most of these facilities are now charging nothing for clean, source-separated wood and are selling it for $20.00 to $45.00 per ton.

The diversion potential of C&D recovery operations were well demonstrated in the 94.5 percent recovery rate experienced by the City of Los Angeles and the Los Angeles Sanitation Districts after the Northridge earthquake. Within a month of issuing a contract, a C&D waste processing line was in place at the landfill. From October 1994 through March 1995, the program diverted over 47,437 tons of dirt and 41,873 tons of concrete from landfill disposal.[17]

Based on the above discussion, and the fact that there is ample inert landfill capacity for non-processible C&D wastes, 100 percent of C&D materials should be diverted from disposal in Class III landfills.

5. White Goods

White goods are large appliances such as dishwashers, refrigerators, etc. These materials contain high-quality steel and are recyclable through existing scrap industries. In 1994, the CIWMB database calculation indicates a total of 36,206 tons of white goods were landfilled from MSW generated in the County. This tonnage should be diverted from disposal in the future, either through separate bulk waste collection programs or separated at the transfer station/landfill.

6. Tire Recycling

As material recovery technologies continue to develop, many successful methods of recycling used tires have emerged. In addition to being retreaded for resale, old tires have been successfully diverted from landfill disposal through use as fuel, playground and athletic

[16] Randy Woods, "C&D Debris: Construction & Dismantling?," *Waste Age*, April 1994.

[17] Janet E. Coke, "Recycling Program Diverts Debris from Earthquake Cleanup," *Public Works*, June 1995.

field subbase, reroofing supplement, material for irrigation channels and other civil engineering applications, road subbase, plastics filler, composting supplement to prevent excessive compaction, and as an additive in modified asphalt. One recent estimate predicts that by the end of 1998, market demand for used tires will exceed the amount generated annually.[18]

Because tires have a high Btu value, they can be processed into Tire Derived Fuel and burned with other solid fuels, or they can be fed whole into cement kilns where they serve as fuel and as a source of constituents needed in the manufacture of cement. A report by the CIWMB notes that the consumption potential of burning shredded tires -- only in cement kilns located in California -- is nearly 25 million tires per year, which exceeds the estimated 21 million waste tires generated annually in California.[19]

Processing tires into crumb rubber for use in asphalt and other applications has significant potential. In particular, there is a huge, multi-billion dollar market for this material as a plastics filler. Overseas markets for tire chips for processing into crumb rubber for new tires is growing as well. BAS Recycling built a crumb rubber plant in San Bernardino, California, that has processed over 1.5 million tires to date.[20] BAS received a $100,000 grant from the CIWMB to transform recycled rubber into playground matting. Shredded tires also have been utilized in construction of drainage systems, retaining walls and other civil works, including landfill construction.[21]

Recovery of tires from the solid waste stream is primarily already handled by companies that market new tires at retail or wholesale, by managers of large fleets, and through such local government programs as bulk waste collection and cleanups. Problem tires are those resulting from illegal dumping or those that get buried in with the regular waste (in roll-offs, for

[18] David Riggle, "Finding Markets for Scrap Tires," *BioCycle*, March 1994.

[19] *Tires as a Fuel Supplement: Feasibility Study*, California Integrated Waste Management Board, January 1992.

[20] *Resource Recovery Report*, July 1995.

[21] *Resource Recycling*, October 1995 and *World Wastes*, September 1995.

example). Because the markets are so promising, the County should work with a manufacturer/exporter(s) to develop facilities and a bounty system to attract tires to market and away from disposal. It is assumed that, coupled with the existing systems, new tire programs, while desirable and effective, will not divert sufficient materials to affect the overall waste diversion rate for LA County.

APPENDIX C

APPENDIX C: LANDFILL CAPACITY CONSERVATION TECHNOLOGIES

Conservation of landfill capacity is a rapidly developing field. Getting the most use out of existing, permitted landfill airspace is particularly urgent in those areas where population densities make siting new landfills difficult, such as the East Coast of the United States, or where the geology is unfavorable (e.g., Florida). Consequently, most of the experience in applying techniques to conserve landfill capacity is from these parts of the country. However, it should be noted that experience with landfill conservation has also been gained by private landfill operators interested in obtaining the maximum amount of tipping fees for their permitted capacity. They, too, are obviously better off placing waste in their airspace rather than cover dirt.

Some techniques are available commercially and others are in development that conserve landfill space and thereby reduce the need for siting new landfills. The first three approaches described below are various Alternative Daily Cover (ADC) technologies that reduce the amount of airspace normally filled with dirt. The remainder are operational changes that follow placement of more waste in the available space. A CIWMB-funded study released in May 1995 noted the value of utilizing these techniques. Some of these techniques can be combined to increase savings (e.g., ADC with baling).

Secondary compaction in large landfills is also a conservation factor. Secondary compaction will occur as lifts of waste are layered upon each other. Fresh Kills Landfill, that has served New York City since 1948, is billed as the world's largest landfill. It covers 2,800 acres and presently accepts 13,000 tons per day. In some areas, the waste is piled 20 stories high.[1] Fresh Kills Landfill reports an in-place density of 1,800 pounds per cubic yard after settlement.[2]

[1] "Environmental Quality Shows Gains and Declines Since 1970, a Report Finds," *New York Times*, December 5, 1995

[2] Anne Magnuson, "The Economics of Landfill Compaction," *MSW Management*, November/December 1992.

1. Alternative Daily Cover (ADC)

The functions of daily cover are to: prevent windblown debris, reduce the amount of precipitation seeping into the filled area, suppress odors from decomposing fill, and deter scavengers (birds, rodents, and insects). Most landfills stockpile and use soil excavated during construction of landfill cells as a source of daily cover; however, this material is often not sufficient for the life of the landfill cell. Consequently, dirt must be purchased and trucked to the landfill site at considerable expense. In areas where suitable soil is scarce or landfill space is particularly precious, public and private landfill owners and operators have used ADCs since the late 1980s. ADCs include chemical or foam covers, tarps (also referred to a geosynthetic blankets), and other ADCs that make use of selected components of the waste stream itself for cover material.

Using the conventional daily cover of six inches of dirt consumes about 26 percent of a landfill's capacity.[3] In the case of the currently operating landfills in the County, this accounts for 16,949 cubic yards of wasted landfill airspace daily,[4] based on the Draft *Solid Waste Quarterly Disposal Quantity Reporting Summary* prepared by the Los Angeles Department of Public Works for the first quarter of 1995. In-place compacted density of cover soil is roughly 2000 pounds per cubic yard, so the cover materials represent roughly 10,000 tons per day of MSW capacity. This approach may over-calculate cover soil airspace requirements slightly, because of the higher-than-average compaction resulting from the weight of overlying layers of waste in extremely deep canyon landfills.

2. Chemical Or Foam Cover

The cost of foam can be a deterrent, particularly for small landfills. An expanding market, plus vendor competition, is helping to reduce the cost of foam. The City of Glendale, Arizona arranged for their vendor to retain ownership of the application equipment

[3] Darlene Snow, "Alternative Daily Cover Material," *MSW Management*, September/October 1994.

[4] Assumes 38,461 TPD disposed daily at 1,180 pounds per cubic yard.

as well as supplying the product. This strategy means the landfill owner does not have to pay the equipment capital cost up front, and competitive bidding is facilitated because the landfill is not locked in to using only a foam product compatible with purchased equipment. Additionally, foam application is less labor- and time-consuming than using dirt, thus lowering costs. Logan Miller, the Delaware Authority's Facilities Engineer, says, "About 20 minutes before we close, they will go over half the working face with the compactors and dozers and smooth it...Approximately half the working face will be foamed prior to closing...As soon as you're done you turn off the foam supply, and approximately 10 seconds later you turn off the air supply. What happens is that in 10 seconds air is blowing through all the lines, blowing the foam. You shut it down and you go home."[5]

The following foam-type materials have been identified:

- AC-645 Long Duration Foam, manufactured and marketed by Rusmar, Inc., West Chester, Pennsylvania;
- ConCover 180, by New Waste Concepts, Perrysburg, Ohio;
- SaniFoam SDC (synthetic daily cover), by CoverFoam Services, Inc., Florence, SC; and
- TerraFoam ADC and Pneumax Compressed Air Foam Systems, by Chubb Environmental Security, Exton, Pennsylvania.

AC-645

AC-645 is a single component foam composed of non-hazardous and non-toxic anionic surfactants and polymers. The product is supplied in concentrated form, in bulk or 55-gallon fiber drums, and is diluted with water prior to application. Foam is generated using a pneumatic foam unit (PFU). The foam is biodegradable, odorless, and non-reactive, can withstand light to moderate rainfall, presents no fire or explosion hazard, and can be colored to provide low visibility.

[5] Lynn Merrill, "ADC Gets the Dirt Out!" *MSW Management*, September/October 1995.

The viscous foam, which has a consistency of shaving cream, can be applied manually to the working face of small landfills, such as NPLF, with a completely self-contained and portable hand-line foam generating unit. The 800 gallon solution tank of the model 800-40 PFU requires three drums of concentrated AC-645 per filling. The concentrate has no shelf-life restriction and the mixture can be applied in winds under 50 mph, hot or sub-freezing temperatures, although storage should be at non-freezing temperatures. Since the foam product is single component and requires no mixing, there is no need to clean clogged nozzles, hoses and other components.

AC-645 can maintain properties for 36 hours after application. The foam does not harden or dry out, although it will freeze when applied in subfreezing temperatures, and is not intended for vehicular or human traffic after application. However, the foam will not deteriorate overnight, and traffic can operate on the foam the next morning when additional solid waste is disposed. At that time, the additional solid waste will compress the foam without reduction of airspace.

Use of AC-645 foam improves leachate management at landfills, due to reduction of isolated cell formation, and minimizes the potential for perched zone seeps. In addition, infiltration of precipitation is minimized and run-off is promoted if the foam is applied in a thick continuous layer.

Rusmar, Inc., foam products have been used as daily cover at other landfills. AC-645 has been permitted for use at the Lycoming County Landfill, Montgomery, Pennsylvania; Grand Central Sanitation, Inc. Penn Argyl, Pennsylvania; Wayne Township Landfill, McElkattan, Pennsylvania; Delaware Central Solid Waste Facility, Dover, Delaware; Empire Sanitary Landfill, Taylor, Pennsylvania; Keystone Sanitary Landfill, Dunmore, Pennsylvania; Northern Tier Solid Waste Authority Landfill, Blossburg, Pennsylvania; Winnebago County Sanitary Landfill, Lake Mills, Iowa; Cherry Island Landfill, Wilmington, Delaware; Pioneering Crossing Landfill, Birdsboro, Pennsylvania; City of Casper-Balefill, Regional Solid Waste Facility, Casper, Wyoming; and Taziguas Landfill, Santa Barbara County, Goleta, CA. Other facilities are awaiting permit approval.

Disadvantages in use of this foam product include: initial equipment cost is high; specialized personnel training is required; direct contact with skin and eyes should be avoided to prevent irritation; it may be difficult to place in wet weather and high winds; and it cannot be traversed by vehicular traffic.

AC-645 foam costs between $.06 and $.12 per square foot, when applied 3 inches to 6 inches thick, respectively.[6] The trailer mounted 400/25 PFU costs approximately $45,000, and can cover the landfill working face at a rate of 300 to 500 square feet/minute. Larger more expensive units can more than double the rate of coverage.

ConCover 180

ConCover 180 is a "long duration" foam injected, spray applied slurry, usable in both daily and intermediate cover applications. The dry feed material, consisting of an "advanced blend" of "earth-based" components, in a self-setting soluble binder and "recycled material" (wood pulp and shredded newspaper as a bulking agent), is slurried with water in a CAPS-180 (ConCover All Purpose Sprayer-180) and entrained with air (foamed) just prior to application.

Three models/sizes of sprayers are available, each manually operated with either a deck-mounted cannon with 200-foot range or 150-foot self-coiling hose and reel. The CAPS machines also can be used for dust control, power washing, fire fighting and seeding.

ConCover 180 was developed for use in high humidity situations, and can be applied in all climate conditions, including rain and hot or cold temperatures. The "cured" foam sheds water to provide good run-off. The material is environmentally safe, non-toxic and biodegradable; color is either blue or brown. ConCover 180 also can be pH-adjusted to accommodate a variety of water quality.

[6]Personal Communication, Kathy Smith, Rusmar Incorporated (November 30, 1995).

The smallest equipment available to apply ConCover 180 is the CAPS 900-180, a 940-gallon capacity trailer mounted unit, which can apply approximately 7,000 square feet of foam, approximately 1 inch thick, in 15 to 20 minutes. Total capacity is 9,000 square feet. Discharge distance is up to 150 feet. The system is reported to cost approximately $35,000, and foam cost is approximately $.08 per square foot (1/2-inch thick).

ConCover 180 has been used as daily cover in a number of landfills. These include: Cumberland County, Fayetteville, North Carolina; Dane County Department of Public Works, Madison, Wisconsin; Wood County Landfill, Bowling Green, Ohio; and Tremont Landfill Company, Springfield, Ohio.

In general, the disadvantages of ConCover 180 are similar to those previously cited for AC-645.

Sanifoam SDC

Sanifoam SDC is a two-liquid component stable aminoplast resin; the two components consist of a foaming agent and a foam stabilizer. The product is diluted with water prior to application and is foamed with compressed air or nitrogen (compressed air normally would be used at a landfill). A pull behind hand-line applicator such as the model PB250-D with two 500-gallon storage tanks would provide 200,000 square feet coverage per application.

The plastic foam, which sets from a fluid to a solid somewhat softer than styrofoam, in 10 to 60 seconds, provides a reflective resilient surface which supports water run-off 15 minutes after application. Maximum water resistance is attained two hours after application. The product is non-toxic and allows plant growth and rooting if part of final cover; also the foam is non-corrosive, contains no irritating, reactive, or pressure generating compounds, and is non-explosive. The foam is non-flammable and self-extinguishing, conforms to OSHA Standards for the workplace, and poses no significant environmental hazard.

[7]Personal Communication, Tim Johnson, New Waste Concepts (November 30, 1995).

SaniFoam SDC can be applied at any ambient temperature, but solutions and material delivery lines must be protected against freezing. It can be applied in moderate winds up to 35 mph (with handheld equipment only) and during light to moderate rainfalls. Once applied and set up, the material can withstand moderate to heavy rain, depending on thickness and method of application. A 1-inch layer of Sani-Foam SDC is claimed to perform equivalent to 6 inches of compacted soil.

The unmixed SaniFoam stabilizer has a shelf-life of approximately 90 days and should be stored in a heated area during cold weather; the foaming agent has no shelf-life restriction. The nozzle used to spray the foam must be cleaned after each use, and equipment flushed with hot water; a hot water flush/rinse down system is a component of the application equipment. Mixing of SaniFoam components and equipment flushing are performed automatically by the equipment.

SaniFoam SDC has been tested and used at several landfill sites, including: the City of Arlington, Texas; City of Corpus Christy, Texas; Outagamie Solid Waste Authority, Appleton, Wisconsin; CDT Landfill, Inc., Joliet, Illinois; Waste Management of Pennsylvania, Inc., Morrisville, Pennsylvania; Peoria Disposal Company, Peoria, Illinois; E.I. Dupont Facility, Victoria, Texas; and U.S. Army Munitions Plant, Texarkana, Texas.

Similar to other foam products, cost of application equipment is high; minimum cost for the PB250-D Spray Bar applicator is approximately $105,000. However, these units will be provided for free by CoverFoam Services, Inc. if the customer commits to long-term use of the foam product. SaniFoam SDC foam costs approximately $.08 per square foot.[8]

TerraFoam

TerraFoam is a natural, biodegradable protein-based material that stays moist after application. Two TerraFoam products are available. The low expansion product lasts 72 hours

[8]Personal Communication, Ernie Straus, CoverFoam Services, Inc. (November 30, 1995).

or longer when left undisturbed. It is wind- and rain-resistant, inhibits fire from starting or spreading, and can be applied to a landfill surface by Pneumax skid units, custom-designed, foam application vehicles operated by one person. TerraFoam can also be applied using a Pneumax Spray Bar unit for larger applications. A higher expansion TerraFoam product, which is produced with additional air-entrainment, can resist wind and light rain for more than 24 hours. Both products are recommended for six-inch thick application.

TerraFoam is environmentally safe and, after application, begins to degrade through evaporation with total effectiveness depending on climate conditions. The product compresses under solid waste disposed the next working day, thus extending landfill life beyond that filled with soil cover.

Currently, TerraFoam is being used at several landfills in California, including: High Grove Landfill, Riverside; San Marcos Landfill, San Diego County; and Ojai Landfill, San Diego County.

Several sizes of delivery equipment are manufactured: a tractor mounted system for large landfills, skid mounted on truck body, and a small trailer mounted unit. The trailer mounted unit can be served by water truck, is simple, requires little clean-up time and components need not be pre-mixed.

The average cost of a 4 to 6-inch thick blanket of TerraFoam is approximately $.10 per square foot. The cost of the small trailer mounted TerraMAC unit is approximately $30,000; application rate is about 250 square feet per minute (5,000 square feet in 20 minutes).

2. Tarp Cover

Tarps or geosynthetic materials are another form of alternative daily cover that can provide dramatic savings in landfill airspace. Although tarps cost considerably more per square foot than dirt, they are cost-efficient due to their reusability.

The following geosynthetic materials have been identified:

- Airspace Saver, manufactured and marketed by Wire Rope Specialists, Baton Rouge, Louisiana;
- Aqua-Shed, by Aqua-Shed Manufacturing Corporation, Florence, South Carolina;
- Covertech C-440, manufactured by Fabrene Inc., Mississauga, Ontario, Canada, and marketed by Covertech Fabricating, Inc., Etobicoke, Ontario, Canada;
- Daily Landfill Covers manufactured by Belton Industries, Inc., Atlanta, Georgia, and marketed by Pallen Enterprises, Inc., Conyers, Georgia;
- Fabrisoil, by Phillips Fibers Corporation, Greenville, South Carolina;
- GeoCover 601, by New Waste Concepts, Perrysburg, Ohio;
- Permalon X-150, by Reef Industries, Houston, Texas;
- Sani-Cover, manufactured by Amoco Fabrics & Fiber Co., Atlanta, Georgia (series 100 and 200) and Hoechst Celanese Corporation, Spartanburg, South Carolina (Series 300), and marketed by Fluid Systems, Inc., Cincinnati, Ohio; and
- Typar DLC (daily landfill cover), manufactured by Reemay, Inc., Old Hickory, Tennessee, and marketed by Exxon Chemical, Summerville, South Carolina.

Geosynthetic products used for ADCs generally are distributed as sheets or panels in rolls or pallets (accordion pleated and rolled or folded). The panels are placed manually or with use of wheeled or track-type vehicles. After application and overlapping, these materials generally are prevented from blowing loose using tires or sandbags as weights. Concrete blocks also are used, but may damage the product if not used with care. Prior to deposition of solid waste during the next working day, the panels are removed and stored for reuse near the working face.

Most geosynthetic products either are woven, nonwoven or are produced as a film. Films resist water and landfill gas penetration whereas the other products generally will allow some gas and water to penetrate to some degree, depending on pore size. This can provide problems in application or roll-back when water increases weight during rainy weather or when water in pores freezes during cold weather use. Geosynthetic products generally are inert, non-reactive,

lightweight, strong, reusable, and flame resistant.

Final cost of a geosynthetic panel is determined by the number of times it can be reapplied (recycled). After final use, the panel can be discarded in the landfill.

Airspace Saver

Airspace Saver is a woven polyethylene fabric, coated on both sides with additional polyethylene to render it water resistant.[9] Maximum standard panel size is 48 x 50 feet; multiple panels can be overlapped to cover a larger area. The manufacturer also can custom fabricate larger pieces by heat welding 12-foot wide panels.

The product is supplied accordion pleated and rolled. Nylon web straps are spaced 12 feet apart and secured to the panels either in one direction or two directions in a checkerboard pattern across the panels. D-rings are attached to the ends of the web steps for ease of installation. The manufacturer will optionally sew a 3/8-inch chain or wire rope into the perimeter of finished panels to aid security in windy weather.

Two products are available. Product TJBX is a 7.2 mil thick fabric weighing approximately 5 oz. per square yard. Cost is $.25 per square foot; rated life is 6 to 10 months, depending on how the material is handled. Product TGNN is 17.2 mils thick, weighing 9.6 oz. per square yard. Cost is $.40 per square foot, with life rated at 1 to 1 1/2 years (some products have displayed a life of approximately 2 years). Cost of chain or wire rope around the perimeter of the finished panel is approximately $2 per linear foot.

Airspace Saver is used in a number of landfills as daily cover. These landfills include, for instance: City of Lynchburg, City Landfill, Lynchburg, Virginia; Chesterfield County, Virginia; and Lunenburg County Landfill, Lunenburg, Virginia. Product TGNN is used at each of these landfills.

[9]Personal Communication, Marion Yarborough, Wire Rope Specialists (May 6, 1993).

The following Waste Management, Inc. landfills use Airspace Saver daily cover: Skyline Landfill, Ferris, Texas; Gulf Coast Landfill, Ft. Meyers, Florida; Hickory Hill Landfill, Ridgeland, South Carolina; Piedmon: Landfill, Kernersville, North Carolina; Brushy Hill Landfill, Little Rock, Arkansas; East Oak Landfill, Oklahoma City, Oklahoma; Central Disposal, Pompano, Florida; Plantation Landfill, Sibley, Mississippi; Quarry Landfill, Tulsa, Oklahoma; and Westside Landfill, Aledo, Texas. Airspace Saver also is used at Thurston County Public Works, Hawk Prairie Landfill, Olympia, Washington; and Winnebago Reclamation, Rockford, Illinois.

Aqua-Shed

Aqua-Shed is a lightweight, reusable, tan colored PVC sheet. For long-term use, as intermediate cover, the sheets are coated on one side with a polybutene aqueous emulsion glue for adherence to the landfill surface. The sheets are 6 mils in thickness and supplied in palletized cardboard boxes in sizes from 168 square feet (28 x 6 feet) to 4800 square feet (100 x 48 feet); this sheet thickness may make installation difficult on windy days. Weight of an Aqua-Shed panel is approximately 50 pounds per 1,000 square feet. Panels soon will be available in rolls.

The panels are not combustible (self-extinguishing) and can elongate 300 percent before breaking; the material is easy to patch. Installation can be accomplished by two persons without mechanical equipment.

Aqua-Shed has been used as daily and intermediate cover on the Kona Municipal Landfill, Hilo, Hawaii. It is reported that Aqua-Shed has reduced incidences of fires at the landfill.[10] The product also has been used at the Bath Landfill, Bath, Maine, where it is noted that the panels could not be punctured with the operator's steel-wheeled compactor.[11]

[10]Department of Public Works, Hilo, Hawaii. Letter signed by Galan M. Kuba, P.E., Solid Waste Division (April 7, 1992).

[11]Kimball Chase Company, Inc., Bath, Maine. Letter signed by Stephen C. DeWick, P.E., Vice President (April 14, 1992).

Cost of Aqua-Shed (unglued) is $.10 per square foot, F.O.B. Florence, South Carolina. Aqua-shed cover is reported to last 90 to 700 days, depending on how it is handled.

Covertech C-440

Covertech C-440 is a clear or pigmented (colored) woven polyolefin fabric.[12] The material is made of high density polyethylene tapes coated on both sides with low density polyethylene. Reinforced web straps support the material on both sides every 12 feet in both directions, with straps extending over the hem with a D-ring. This design allows for easy installation over compacted solid waste using existing equipment or manpower. None of the woven polyolefins are considered hazardous under normal conditions. The material is stable, chemically inert, and does not present a health hazard.

Due to the fabric's high slip factor (compared to non-woven materials) the cover can be dragged easily on and off solid waste. If the area to be covered is small (e.g., 48 x 50 feet), two to four persons can easily drag it over the working face. The material is secured with tires or sandbags; however, the manufacturer will include an optional chain in the hem for added weight around the perimeter.

Life expectancy of Covertech C-440 is between 10 and 18 months, depending on use. Cost is $.40 per square foot, and it is supplied with one dimension in multiples of 12 feet, up to 72 feet (stock size is 48 x 50 feet).

Covertech C-440 has been used at a number of landfills: Pottstown Landfill (Waste Management of PA, Inc.), Pottstown, Pennsylvania; Kankakee Recycling & Disposal Facility (Waste Management of Illinois, Inc.), Kankakee, Illinois; B.F.I. Charlotte Motor Speedway Landfill, Charlotte, North Carolina; B.F.I. Samson County Landfill (Roseborough, North Carolina); B.F.I. Muskigum Landfill (Zanesville, Ohio); and others.

[12]This product is identical to Airspace Saver.

Daily Landfill Covers

Daily Landfill Covers are fabricated to specific requirements from wide width panels of woven polypropylene. A wide-range of fabric weights (ranging from 3.8 to 8 oz./square yard), strengths and blanket configurations are offered. The basic cover can be manufactured with pockets on each corner to facilitate ease of movement in all directions either manually or with machinery.

The material generally is available in 12.5 foot or 15 foot widths which can be fabricated, double-stitched, into covers up to 75 feet wide and any desired length. Rolls come on 4-inch diameter heavy duty corrugated cores.

Panels are either black, grey, or white in color, and also can be supplied with straps and D-rings at corners. Of six styles offered,[13] styles 796 and 113 generally are used by landfill operators. Style 796 is a 5.4 oz. per square yard black fabric costing $.20 to $.22 per square foot, depending on size. Style 113 costs $.30 to $.32 per square foot and weight 8 oz./square yard. Cost includes web straps and D-rings.[14]

Daily Landfill Covers are used at a number of landfills. Style 796 is used at the Hall County, Georgia, Landfill and City of Macon, Georgia, Landfill. Style 113 is used in 75 x 100-foot panels at BFI and Chambers Development Company landfills, and others. These include, for instance: Roberts Road Landfill, Fayetteville, Georgia (BFI); Oak Ridge Landfill, Dorchester, South Carolina (Chambers) and Chambers Atlanta Landfill, Georgia.

Fabrisoil

Fabrisoil reusable ADCM is a nonwoven, needlepunched polypropylene fabric which is heat set on both surfaces. The staple fiber, needlepunched, heat set construction provides a 3-

[13]Styles 768, 507, 776, 777, 796 and 113.

[14]Personal Communication, Gregory T. Pallen, Pallen Enterprises (May 6, 1993).

dimensional structure which resists snagging on solid waste, and will not de-laminate on reuse.

Generally, a Fabrisoil panel can be used as long as two weeks or more. The panels are shipped folded accordion-style, then rolled up.

Fabrisoil is strong enough to be pulled into place with existing equipment, and if the area is small (say 30 x 50 feet), two persons can easily install. Edges are secured every 20 feet with tires or sandbags. If it is windy, more anchoring may be required. Typically a 100 x 100-foot area can be covered in 10 to 15 minutes. This represents a reduction in time of installation of 85 percent compared to installation using soil as daily cover.

Fabrisoil has been used on more than 20 landfills. At the Rowan County Landfill, Salisbury, North Carolina, the average working face is 100 x 100 feet. At the McLean County Landfill, Bloomington, Illinois (owner-operator John Sexton Contractors Company), life of the Fabrisoil is 15 to 20 uses, saving about 167 cubic yards of airspace per day (daily working face measure 90 x 100 feet).

Fabrisoil costs about $2 per square yard (approximately $.22 per square foot).

GeoCover 601

GeoCover 601 is a nonwoven geosynthetic polypropylene fabric. Each GeoCover 601 panel is custom made specifically for the customer and is delivered to the landfill site ready to use. The manufacturer suggests that panels be no wider than 80 feet. The cover is lightweight (6 oz. per square yard) and has a very low moisture absorption rate, making it easy to handle. The panels are constructed with webbing sewn around the perimeter and with handles every 20 feet.

The product is rolled or dragged, either manually or with on-site landfill equipment, across the surface of the landfill; life of the material depends on how it is handled. For instance, use in Wayne, Michigan, has displayed a life of approximately 30 days. At a site in

Minnesota, a 6-month life was observed.

The product is "certified" for use at landfills in 15 states.[15] Cost is $1.20 per square yard.

Permalon X-150

Permalon X-150 is described as an "alloyed high-density, PE membrane." The product is manufactured with 12 layers of polyethylene oriented in the machine direction, the transverse direction and at 45 degree angles to both directions. Stock size sheets are available up to 100 x 100 feet, constructed of 4-foot wide heat-seamed panels; larger sheets are available up to 200 x 200 feet. All covers can be custom fabricated with grommets, pipeloops, etc. . Thickness of Permalon X-150 is 8.6 mils, with a weight of 30.4 lb per 1,000 square feet.

The product is watertight, but currently is not fire retardant.[16] Cost of Permalon X-150 is $.10 to $.14 per square foot depending on quantity ordered. Currently, the manufacturer is testing an improved product, with geotextile backing (6 oz. nonwoven). Cost is projected to be $.18 to $.20 per square foot.

Permalon X-150 is used at the North Western Landfill (Mid-American Waste Systems), Parkersburg, West Virginia, and the County Environmental Landfill (Envirite Corporation), Pontiac, Illinois.[17]

Sani-Cover

Sani-Cover is available in woven polypropylene (Series 200), non-woven needlepunched polypropylene (Series 100), and non-woven needlepunched "Trevira" 100 percent continuous

[15]Personal Communication, Berthold Rossnagel, New Waste Concepts (May 4, 1993).

[16]Personal Communication, Lynn Ciolli, Reef Industries (May 6, 1993).

[17]Personal Communication, Ralph Jelic, R.A. Jelic Company (May 7, 1993).

filament polyester fabric (Series 300), to serve various field conditions. Non-woven polypropylene and polyester panels provide higher elongation characteristics which reduce the possibility of sharp or pointed objects tearing or puncturing Sani-Cover during deployment. Woven polypropylene, on the other hand, displays water repellency for use in rainy climates.

Sani-Cover is designed for quick and easy deployment using minimal time and labor. For instance, bars can be inserted into pockets sewn into the finished panel for ease in pulling across the landfill working face. The product either can be installed using on-site landfill equipment or it can be deployed manually.

A standard size panel, approximately 100 x 100 feet, can be installed by three persons in approximately 10 minutes.[18] Panels can achieve a lifecycle of more than 60 days use. The cost of Sani-Cover is $.15 per square foot, F.O.B. plant at Dallas, South Carolina.

Sani-Cover is being used at more than 100 landfill sites around the country. On the east coast, these sites include: City of Waco, South Carolina; City of Greensboro, North Carolina; Caldwell County (Hudson, North Carolina); Southern Solid Waste Management Center, Georgetown, Delaware; and Millersville Landfill, Anne Arundel County, Maryland.

At the Millersville Landfill, two Series 200 panels, each measuring 150 x 150 feet, were purchased at a cost of $6,000. The first panels was replaced after seven weeks use. As of May 1993, the second panel had been in use three weeks. Material from the first panel currently is being used to line stormwater diversion ditches and other structures, thereby extending the useful life. Landfill personnel at Millersville are satisfied with Sani-Cover.[19]

[18]Personal Communication, David Powell, Fluid Systems (May 5, 1993).

[19]Personal Communication, Dub Deeson, Millersville Landfill, Anne Arundel County, Maryland (May 27, 1993).

Typar DLC

Typar DLC is made from thermally-spunbonded (non-needlepunched) polypropylene fibers.[20] Standard size fabric panels, in stock, measure 46 x 100 feet; however, the manufacturer can fabricate custom-made panels in any size. Panels are shipped accordion-folded and rolled for ease of application. Depending on how panels are handled, use can extend for at least a year (the vendor advertises a 6-month life). Panels do not snag; however, if necessary, they can be repaired easily.

Although the product is permeable, Typar DLC tends to shed water. In addition, the product does not take on water or excess soil during use, which would increase weight and cause problems in handling.

Typar DLC can be installed using existing machinery or can be handled manually. A 46 x 100 foot panel weighs approximately 200 pounds (about 6.25 oz. per square yard and can be deployed in 10 or 15 minutes by three people). Cost is $530 (about $0.11.5 per square foot).

Among others, Typar Daily Landfill Cover is being used at the Pekin Metro Landfill, Pekin, Illinois; Clinton Landfill, Clinton, Illinois, and Taswell County Landfill (Waste Management of Illinois), East Peoria, Illinois, where service life of panels has exceeded six months.

3. Other ADC Technologies

Alternative daily covers used by some communities make use of materials that would otherwise be part of the waste stream. An example is the fine material generated by Construction and Demolition debris (C&D waste) processing that consists primarily of soil and shredded wood utilized by Waste Management at the Collier County Landfill in Florida. C&D processing now diverts much of the C&D material from disposal, and the fines ADC, which

[20]Personal Communication, Tom Miller, Exxon Chemical (May 7, 1993).

would have been landfilled in the past, now saves the operator $250,000 per year that would have been spent on cover dirt.[21]

Another ADC that is familiar to Los Angeles County is the use of ground green wastes. The Los Angeles Sanitation Districts estimate that up to 600,000 tons (roughly half) of the green wastes could be used as ADC per year. However, because of opposition by the Natural Resources Defense Council (NRDC), the CIWMB may change its policy of counting the use of green wastes used as ADC toward achieving the County diversion goal. The CIWMB considered the problem, and recently confirmed its decision to accept green waste ADC as diversion until such time that adequate markets for green waste compost and mulch develop.

Finally, several commercial slurry products make use of recycycled materials. The following slurry-type materials have been identified:

- ConCover, manufactured and marketed by New Waste Concepts, Perrysburg, Ohio; and
- Posi-Shell, by Landfill Service Corporation, Apalachin, New York.

ConCover

ConCover is an ADCM engineered for use as a daily landfill cover with a life expectancy of 1 to 10 days. The "earth based" polymer spray-applied slurry is composed of two components: a fiber matrix and polymer binding agent. The fiber matrix (bulking agent) is prepared with recycled shredded newspapers and wood pulp.

ConCover can be mixed and applied with the same equipment used to apply ConCover 180, described earlier in this Appendix (see Foam Products). Complete coverage can be attained with a 1/4-inch thick layer, which provides protection equivalent to 6 inches of soil. In approximately 60 minutes, the cover will resist climate conditions; prior to that time, the product

[21] Lynn Merrill, "ADC Gets the Dirt Out!," *MSW Management*, September/October 1995.

is subject to deterioration if an extreme rainfall takes place. ConCover performs best in lower humidity conditions.

At the landfill in Wood County, Ohio, ConCover replaces approximately 150 cubic yards of daily soil cover, saving approximately 43,000 cubic yards of air space annually.[22] Each morning, the mobile spray equipment is filled with 200 gallons of water, to be used for dust control and on-site fires, if necessary. At the end of the day, landfill personnel add bags of ConCover (and an additive, if it is raining). The mixed slurry is then applied over the 150 x 40 foot working face in about 15 minutes, forming a crust in 30 minutes to 1 hour.

ConCover also is used at two landfills in the State of Iowa. These include the Linn County Landfill, which serves the area around Cedar Rapids, and the Webster County Landfill, which services the area around Ft. Dodge.

The cost of ConCover is $.07 per square foot, with equipment cost the same as cited with ConCover 180.

Posi-Shell

Posi-Shell is an environmentally compatible combination of: a filler consisting of a mixture of solids containing 100 percent recycled cellulose fibers and plastics; and a recycled alkaline mineral binder liquid; which is formulated to be mixed either with water or landfill leachate, and sprayed onto the landfill surface. The mineral binder component acts to neutralize odors and contaminants present in landfill leachate. After application, the Posi-Shell slurry hardens to an earth-tone, non-flammable coating.

A horizontal mobile silo is used to store and dispense the binder and a mobile Posi-Shell Applicator mixes ingredients supplied in Posi-Pak bags, and maintains the slurry in constant agitation prior to application. Larger landfills may require multiple set-ups. The mobile

[22]Landfill Uses Old Newspapers as Daily Cover Materials. Pollution Engineering, pp. 122-123 (September 1991).

The increased moisture content from recirculating leachate promotes biological activity, resulting in faster decomposition of organic materials and a concomitant increase in the rate of landfill gas production. The more rapid loss of solids from decomposition in the landfill speeds the consolidation of the landfilled material and the resultant settling.

Laboratory studies of leachate recirculation have shown that decomposition periods can be reduced to 18 to 36 months, as opposed to the 20- to 30-year period normally associated with refuse decomposition.[24] Although these studies are done on small-scale models and field tests do not reveal such dramatic increases in stabilization rates, leachate recirculation has proven to have a considerable effect on waste decomposition in landfills. At the Alachua County Southwest Landfill in Florida, it was assessed that in cells with leachate recirculation, the half-life of the waste's biodegradable mass was decreased to 3 to 5 years; this compares to a half-life of 10 or more years for the waste in untreated sections of the landfill.[25]

2. Biostabilization

An evolving concept of landfilling, stabilized placement or biostabilization, is gaining significant interest as a means to substantially conserve landfill space, particularly where disposal capacity is at a premium and conservation of natural soils is important. In the biostabilization process, following the removal of recyclables, solid waste to be landfilled is shredded and the moisture content is adjusted (preferably to between 40 and 60 percent). The shredded waste is then aerated for a period of 60 to 90 days. Following the aeration period, the waste is compacted with standard landfill compaction equipment. Experience at an operating facility in Albany, New York indicates that after biostabilization, 50 to 100 percent more refuse can be placed in the landfill cell when compared with conventional landfilling.[26]

[24]Kevin O'Leary, "Development of Leachate Disposal Processes," *Waste Age*, July 1995.

[25]T. Townsend, W. Miller, R. Bishop, and J. Carter, "Combining Systems for Leachate Recirculation and Landfill Gas Collection," *Solid Waste Technologies*, July/August 1994.

[26]David L. Hansen, "Biostabilization of Landfill Waste," *Waste Age*, June 1995.

3. Baling

Baling solid waste prior to landfill disposal is another technique that has proven to conserve landfill space. By operating the landfill as a balefill, on average, 45 percent greater compaction will be achieved when compared with conventional compaction methods. Typical bales (3' x 5' x 4') of MSW weigh up to 3,000 pounds, and a well-designed and operated balefill may consume less than half of the equivalent active fill or cell area as a conventional landfill operation for the same tonnage of waste and the same height of fill.

At the Jonesboro Landfill in Craighead County, Arkansas, an initial density of 1,500 pounds per cubic yard is achieved by feeding the waste through a baler prior to disposal (a 25 percent increase over the density estimated for Elsmere).

4. Landfill Reclamation (Mining)

Landfill reclamation, or landfill mining, is the excavation and mechanical processing of previously landfilled material to recover materials or landfill airspace, reduce the size of the landfill, or transfer material from an unlined to a lined landfill.

An extensive evaluation of a landfill mining site was performed in Collier County, Florida by the U.S. EPA's Risk Reduction Engineering Laboratory. During a two-week demonstration period in 1992, County staff mechanically processed 292 tons of excavated material through coarse and fine screens, an air knife/de-stoner, and magnetic separators into nine fractions. Two of these fractions -- a soil fraction and a ferrous metal fraction -- were determined to be reusable. The recovery of ferrous metals averaged about 75 percent with a purity of 82 percent.[27]

A reclamation project at the Frey Farm Landfill, in Lancaster, Pennsylvania, involves continual hauling of the excavated waste to a neighboring WTE facility. The Lancaster County

[27]John T. Aquino, "Reclaiming Landfills: Amazing Interest," *Waste Age*, February, 1994.

Solid Waste Management Authority (LCSWMA) reports that revenues from the sale of electricity and recovered ferrous metal offset operating costs of the landfill reclamation project and result in net revenues of $3.94 for every ton of reclaimed refuse delivered to the WTE facility. Additionally, the mining operations are creating 2,500 cubic yards of vacant landfill space each week.[21]

APPENDIX D

APPENDIX D: SEATTLE, WASHINGTON CASE STUDY

A. INTRODUCTION

The successful recycling program in the City of Seattle, Washington proves that diversion rates of 50 percent and beyond are realistic and obtainable. The latest recycling program studies reveal that Seattle experienced a 48.2 percent recovery rate in 1993. Given that Seattle's diversion rate has leaped from 22.0 percent in 1985, to 40.0 percent in 1990, to 48.2 percent in 1993, it can be inferred that the current recycling rate is well over 50 percent.[1] The following is a summary of the management and success of Seattle's waste and recyclables collection system.

B. BACKGROUND AND LEGISLATIVE FRAMEWORK

Seattle's Solid Waste Utility was established in 1961 to manage collection and disposal of waste in the City of Seattle. It is a public Utility of the City of Seattle and a division of the City's Engineering Department. The Utility, which was established as an Enterprise Fund, is self-supporting, primarily by user fees, and receives no subsidies from the City's General Fund.

The Utility functions both in an administrative role and as a direct service provider. It contracts with private companies for residential waste and residential recyclables collection and processing services; develops overall policies that affect private collection of commercial waste; and contracts for solid waste transport and disposal, as well as certain household hazardous waste transport and disposal services. It also owns and operates transfer stations and a permanent household hazardous waste drop-off facility.

Resolution 25872, adopted by Seattle's City Council on August 14, 1978, called for establishment of recycling goals, and stressed the importance of market stability, source separation, and support for the existing recycling organizations. Recycling targets in the City

[1] "City of Seattle November/December Curbside Recycling Report," City of Seattle, February 1995.

have been steadily increasing since the late 1970s. In 1988, the City Council adopted Resolution 27871 establishing the solid waste management policies that are the basis for Seattle's Integrated Solid Waste Management Plan (the Plan). The Plan is adopted by the City under the authority of the Revised Code of Washington, 70.95.080 (1), which allows the City to "prepare and deliver to the County auditor of the County in which it is located, its plan for its own solid waste management for integration into the comprehensive County plan."

The Plan sets waste reduction and recycling goals of 40 percent by 1991, 50 percent by 1993, and 60 percent by 1998, and it directs the Utility to implement the waste reduction, recycling, composting, and disposal programs necessary to achieve these goals. Resolution 27871 also mandates a schedule for implementation of these programs and expresses the intent of the City of Seattle to manage the disposal of its residential and commercial solid waste independent of King County.

C. COLLECTION AND TRANSFER SYSTEM

1. Residential Collection

The City contracts with two local companies, U.S. Disposal (owned by Rabanco, Inc.) and General Disposal (owned by Waste Management, Inc.), for mandatory, weekly residential waste collection (including single-family households and multi-family properties of up to four units) in three areas of the City. The contractors serve approximately 250,000 households. Customers are offered a choice between curb/alley and backyard collection, with a 40-percent rate discount incentive for choosing curb/alley collection. For curb/alley customers, contractors supply containers sized according to the customer's chosen level of service, ranging from a mini-can (19 gallons) to a 90-gallon cart. A pre-paid trash sticker is also available for excess waste.

Waste generated by Seattle households and collected by the two City contractors is hauled to one of two City-owned transfer stations. The waste is then transferred to City trucks and hauled by the City to the rail yard transfer station. It is then rail-hauled to Columbia Ridge

Landfill in Arlington, Oregon, which is owned and operated by Washington Waste Systems, a subsidiary of Waste Management, Inc.

In 1988, the City began offering curbside collection of recyclables to residents. Curbside recycling services are offered on a voluntary, subscription basis to 148,500 single-family households and multi-family units (up to four-plexes) by two local hauling companies: Recycle America and Recycle Seattle. The North-side contractor, Recycle America (a Waste Management Company), provides weekly pick-up of recyclables in three, 15-gallon stacking bins -- one for newspaper, one for mixed paper (all forms of residentially-generated paper, e.g., newspaper, magazines, junk mail, cereal boxes, and corrugated cardboard), and one for glass, plastic (PETE and HDPE), and metal (tin, aluminum, and bimetal) containers. The South-side contractor, Recycle Seattle (a Rabanco Company), provides monthly pick-up of the same materials in 60- or 90-gallon wheeled toters. To alleviate some of the glass breakage occurring during commingled collection of the materials, Recycle Seattle has provided customers with a small container for glass storage that hooks onto the outside of each toter.

The City also provides contracted curbside collection of yard trimmings. Curbside yard trimming collection service is provided by two companies: (1) General Disposal Corporation provides weekly pickup year-round; and (2) U.S. Disposal Service provides bi-weekly pick-up from March through October, and monthly pick-up from November through February. Yard trimmings are also accepted from businesses and residents at the two City transfer stations. All yard trimmings collected in the City are then hauled to Rabanco's Cedar Grove Compost Facility for processing. The City also operates an education program to encourage backyard composting.

Except for yard trimmings, there is no additional charge for curbside recycling services. Residents are charged monthly for yard trimming collection; the cost of collecting other recyclables is included in the residential fee structure. A multi-family recycling program targeted at multi-family residences with more than four units began in 1993.

In addition to the City's curbside recycling program, the two City transfer stations provide drop boxes for all materials accepted at the curb, as well as vehicle batteries, motor oil,

oil filter containers, mattresses, "sharps" (i.e., needles), ferrous and non-ferrous scrap metal, and used lumber and wood. Residents can drop off these materials free of charge. White goods and used automobile tires are accepted for a charge.

The Utility participates in the Regional Household Hazardous Waste Program and has owned and operated a permanent household hazardous waste facility (located next to the South Transfer Station) since 1988. The facility is open to both City and County residents.

2. Commercial Collection

Commercial solid waste collection in Seattle is regulated by the Washington Utilities and Transportation Commission (WUTC). Although the City has the authority to contract for commercial waste collection, and may do so in the future, Seattle's businesses and industries are served by four collection companies holding certificates from the WUTC. The City monitors WUTC decisions and, through the Plan, establishes recycling service levels, rate structure requirements, and data-reporting requirements necessary to meet the City's recycling goals. Although the City does not set rates for commercial collection, it participates in WUTC rate hearings to ensure a rate structure that encourages waste reduction and recycling in accordance with the Plan.

3. Government/Institutional Sector Collection

City government buildings are considered a residential customer; they use dumpsters and receive waste-collection services from Rabanco and Waste Management. Other government buildings and most City institutions contract for waste collection with private haulers.

4. Transfer Stations

There are four transfer stations located in Seattle where collection vehicles transfer waste to larger transfer trailers (rail cars) for long-haul to the Columbia Ridge Landfill in Arlington, Oregon. Two of the transfer stations are owned and operated by the City within the Enterprise Fund. Generally, the two City-operated transfer stations serve the self-haul customers and the residential collection contractors hired by the City.

The two private transfer stations are owned and operated by two private companies that collect waste from commercial accounts in Seattle and outside of the City. One such facility, owned by Rabanco, receives, processes, and transfers many different types of materials, including recyclables from the residential curbside recycling contract, commercial paper loads, construction and demolition debris, and commercial MSW. The Eastmont Development Transfer Station, owned and operated by Waste Management, receives waste from Bayside Disposal and other collection firms operated by Waste Management in the Seattle area. Waste from commercial and industrial accounts inside and outside of the City and residential waste from outside of Seattle are delivered to the Eastmont Development site.

D. VARIABLE RATES

The City Utility has instituted a weight-based rate system, which is calculated by the size of the container provided to each generator. As shown in Table A-1, rates range from a 12-gallon "Micro Can" at $9.37 per month up to a 90-gallon cart at $44.94 per month for curbside collection. The Utility has experimented with on-board weighing systems to provide more accurate weight-based fees, but has not implemented a full-scale program.

Collection service also provides, for the larger can sizes, the option of backyard (rather than curbside/alley) service for an additional cost. Note that there are no charges for recyclables collection, and the $3.00/month rate for yard waste collection is set low enough to encourage resident diversion.

Table D-1. City of Seattle, Washington Rates

Residential Monthly Rates of Containers

	Weight Limits	Curb/alley	Backyard
Micro Can (12 gal)	- 20 lbs.	$ 9.37	not available
Mini Can (19 gal)	- 30 lbs.	$11.50	not available
32 Gallon Can	- 60 lbs.	$14.98	$20.96
60 Gallon Cart or (2 32-gal)	- 120 lbs.	$29.96	$41.94
90 Gallon Cart or (2 32-gal)	- 180 lbs.	$44.94	$62.92
Yardwaste 5 units/week	- 60 lbs.	$ 3.00	not available

Disposal Stations Fees and Charges
(Reyclables can be dropped off free of charge)

	White Goods (large appl.)	Garbage, Tires and Mattresses	Clean Yard Waste Clean Wood Waste
Passenger vehicle	$14.00/item	$ 7.00/trip	$ 6.00/trip
Non-passenger vehicle	$14.00/item	$83.00/ton	$64.00/ton
Minimum disposal fee Non-passenger vehicle	$14.00/item	$13.50/trip	$10.00/trip

"Clean" means a load is entirely yard waste or entirely wood waste. Mixed loads will be charged the garbage rate. If you bring yard waste and garbage in the same vehicle, you pay the rate for garbage.

Yard waste and garbage must be separated prior to disposal.

If you bring appliances and garbage in the same vehicle, you pay the rate for garbage plus $5 per appliance.

Source: *The Economics of Recycling and Solid Waste Management for the 90s*, Harvey Gershman, GBB, Municipal Waste Management Association, March 24, 1994.

Similarly, there is no fee for recyclables drop-off at Disposal Stations, where residents can bring bulk wastes.

E. RECYCLABLES DIVERSION

The key to the success of the City of Seattle's recycling program is the participation rate among eligible households. As of December, 1994, 91.1 percent of the 149,500 eligible households are participating in the City recycling program. On the North Side of the City, 98.9 percent of the households participate. In addition, Seattle averages five new sign-ups per day.[2]

The latest quantitative analysis of the recycling program, which is for the year 1993, revealed that the City of Seattle experienced a 48.2 percent diversion rate. The breakdown of generation and diversion rates for each waste component is included as Table A-2.

In 1985, 22.0 percent of the waste in Seattle was being recovered, and in 1990, a 40.0 percent diversion was experienced. Given the 1993 diversion rate of 48.2 percent, and recognizing the upward trend in recycling recovery rates, it seems Seattle is on target to reach the 1998 goal of 60 percent diversion.

APPENDIX E

APPENDIX E: ENTERPRISE FUNDS AND FULL COST ACCOUNTING

This Appendix discusses some of the cost issues relevant to integrated solid waste management planning. It is not possible to develop a detailed cost plan for the recommendations made in the report. To do so would require obtaining present cost data from the County and the County Sanitation Districts of Los Angeles County, as well as from each of the Cities in the County.

Determining the actual cost of solid waste management is one of the most difficult tasks encountered by communities developing integrated solid waste management plans. Many costs, particularly overhead costs such as personnel management, are handled by separate departments. The amount of time allocated to management of solid waste personnel must be estimated as part of the overall cost of solid waste. In addition, divisions often share equipment, marshalling yards or supervisory personnel, or pitch in together to provide emergency services, making it difficult to identify solid waste-specific costs.

The objective in this Appendix is to get the County thinking about how to develop a coherent integrated solid waste management system and help communities control costs. The County can function in a key coordinating role. This does not mean that the County shoulders all costs or manages all facilities; it means that the County actively supports the Cities and facilitates their operations. Elaborate solid waste systems can be very costly if program components are added piecemeal. County leadership can be critical in this area through:

- preparing the County Comprehensive Plan to coordinate efforts between the various County jurisdictions or provides joint City/County-sponsored facilities;
- developing facilities that serve multiple jurisdictions (e.g., transfer stations) that, through economies of scale, keep costs down despite possible longer haul distances;
- developing County model programs, including a variable rate fee system for County-collected areas and technology demonstration programs for landfill operations (see Chapter IX.F); and
- maintaining the economic viability of existing facilities, for example, through waste transfer to the WTE facilities (Chapter IX.H) or developing a policy of purchasing

supplies from recycling enterprises ("Buy Recycled") that utilize recyclables collected in Los Angeles County.

In addition to the coordinating role, the County can pioneer some innovative ways of financing solid waste management programs that also foster diversion of waste from disposal, including: enterprise fund accounting, and variable rate fees ("unit pricing"). Also discussed in this Appendix are the relative share of the solid waste dollar cost for different system components, and factors influencing costs. These two topics provide background for Report discussions.

A. ENTERPRISE FUNDS

Operating an integrated solid waste management system as an enterprise fund allows communities to track the true cost of service, and keeps the funding for services separate from the political vagaries of the government budgeting process. In an enterprise fund, all revenues and costs go to a cost center. Revenues do not go to the General Fund, debt service is not paid for by Finance, benefits by Personnel, or fuel by the Transportation Department, etc., which is often the case when solid waste is part of a jurisdiction's operation. Future post-closure costs and sinking funds are established in enterprise accounting, and it possible to tell the cost for solid waste service and charge for it -- by the ton, by the household, by the business address, etc.

B. VARIABLE RATES

Local governments need to find ways to charge the generator for the service received in order to get solid waste costs out of the General Fund. Direct billing of customers for the solid waste service received is a key component of enterprise fund accounting. These fees, plus other revenues such as from the sale of recovered materials, make up the funds used to pay costs. Generator billing should be done in a way that encourages source reduction as well as maximizes diversion. A variable rate system (also called "unit pricing") goes far to accomplish this and is also an important part of enterprise accounting for solid waste management. Variable rate pricing has been the norm in commercial collection for years -- the generator is billed based

either on the weight of the material collected by the hauler, or by the size of the waste storage container used by the generator. For the residential customer, it can mean higher costs for more waste, or lower costs for less waste and more recycling. For the commercial generator, it can mean differential fees (or no fee) for loads that can be recycled. As consumerism is applied to solid waste services, the generator will have incentive to dispose of less and to set aside more materials for recycling. An example of a variable rate fee system is provided in Appendix A, Case Study of the City of Seattle.

C. COSTS FOR SOLID WASTE SERVICES

The solid waste dollar goes to many functions, depending upon the make-up of the specific system. Shown in Figure E-1 is a pie chart, developed from data from several cities, that graphically portrays how the solid waste dollar is split up. Administrative costs for each of the components are included in each portion of the pie. As can be seen, collection-related costs comprise over 60 percent of the pie, followed by disposal at 30 percent, and lastly by processing at 8 percent. It should be noted that solid waste collection includes bulk waste and special collections (such as post-special event collections and disaster debris), while recycling collection costs include yard waste collection as well as curbside service for materials. The pie chart shows recycling-related collection costs at 20 percent -- or almost one-third of the collection expenditures. Recycling costs overall can represent over one-quarter of the way the solid waste dollar is spent.

In addition to the above service-related and direct administrative costs, a community can expend considerable funds on specialized services, such as Household Hazardous Waste (HHW) collection and public information campaigns to encourage recycling and HHW diversion. Many communities have turned to surcharges on landfill or transfer station tipping fees as a means of funding new diversion programs, particularly for programs such as HHW that have a high unit cost and do not produce revenues to help pay for the program. Monies collected through surcharges can "get lost" in the General Fund; enterprise fund accounting can keep these resources dedicated to solid waste management programs.

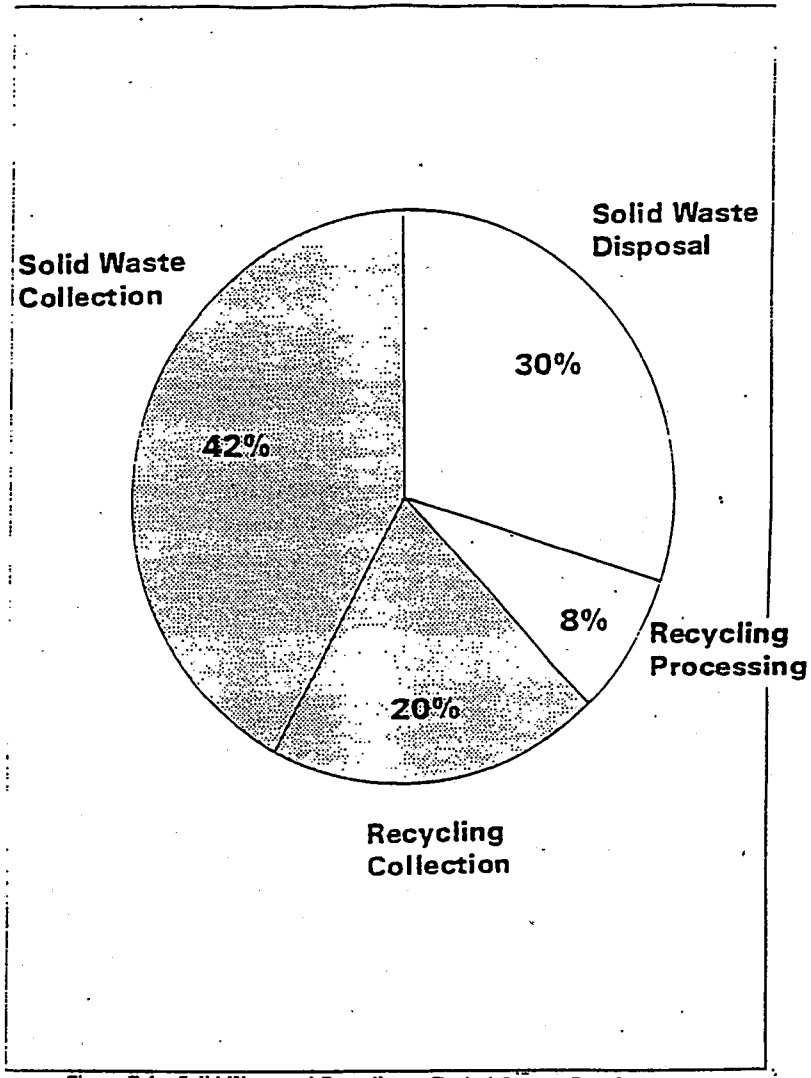

Figure E-1. Solid Waste and Recycling – Typical System Cost Components

D. FACTORS INFLUENCING COSTS

Trends that influence recycling and solid waste disposal costs are discussed in various Report Chapters, and are summarized here by the service component. Overall, the cost of solid waste management is rising, but offsetting trends are discussed as well.

1. Collection

Two factors are driving the cost of solid waste collection. First, obtaining high-quality recyclables from the waste stream often means curbside collection of source-separated designated materials. This adds specialized recycling collection trucks and personnel routed through the same neighborhoods as the solid waste collection packer trucks. Yard wastes are also collected through a separate route system. Bulk wastes may also be collected separately using open-bed trucks equipped with a grapple. Each additional collection system will increase the number of trucks and personnel needed to get the job done.

Second, as the solid waste management system has evolved, the equipment industry has been evolving along with it. Automated collection equipment allows a single driver to complete a route, rather than the two- or three-man crews required for traditional packer trucks. Sophisticated routing software and GIS mapping allow a jurisdiction to consolidate routes, so that as recycling collection expands, solid waste collection routes can be adjusted proportionally, and optimum routes (i.e., the most material in the least time) can be devised for each type of collection. Other equipment features, such as split packers, allow a single truck to perform double duty while on a route. These options can be used to reduce the cost of collection.

Communities are innovating to contain the costs resulting from these trends. Automated collection has been applied to recyclable materials as well as refuse. Rebanco in Seattle has utilized authomated recycling collection in 96 gallon carts and reduced the collection frequency to once per month. Guelph, Ontario is implementing wet/dry collection citywide in the city, with a population of 80,000. This followed an extensive pilot program to establish the cost and effectiveness of the program. Because the collection function represents a majority of the solid

waste management cost, efficiency in this area has the largest reduction in overall cost for the investment.

2. Transfer

Collection costs can also be contained by adding transfer station(s) to the system. As discussed in Chapter IX, transfer stations can reduce collection costs by keeping collection packer truck routes as short as possible (less than 30 miles). A transfer trailer can carry three times the amount of waste as a packer truck and rail cars can carry six times the amount. Shifting the waste to larger-capacity, more efficient transfer vehicles for transport to the disposal site reduces the number of personnel and vehicles needed.

Even though transfer operations add capital and operations costs for transfer stations and vehicles, they have the potential to significantly reduce the overall cost. The reduction in the non-productive time for the route collection trucks has a double pay-off. First, the cost per collection route is reduced and second, the route collection trucks can collect from additional routes. This lowers the investment in trucks and crews.

3. Solid Waste Disposal

Class III Sanitary Landfills are still the primary method of managing solid waste in Los Angeles County. The cost of landfill disposal is a political issue as well as a technical one. The true cost of local landfill disposal is not reflected in $20.00 per ton tipping fees. Some long-term costs of landfill disposal can be deferred (rather than paid out of tipping fees), particularly closure, post-closure, and Title V Remediation Funds, plus, for existing landfills, the cost of the site may have already been paid for and does not reflect current land values. However, a jurisdiction may choose to keep landfill prices low in order to keep waste from leaving to lower-cost disposal sites in order to maintain cash flow at the landfill, or (as in the case of Orange or Riverside Counties) may reduce the price to attract waste from outside the jurisdiction and thus increase cash flow in the short term.

The actual cost of landfill disposal is driven by the cost of the land, pre-development costs for planning and permitting, plus the construction and operation costs of the facility over its life. The U.S. EPA promulgated new rules for landfill management on October 9, 1991. These rules, as subsequently adopted by the State of California, set standards for:

- Location. Includes limits on proximity to airports, 100-year floodplains, wetlands, fault areas, seismic impact areas, and unstable areas.
- Design. Requires composite liner and leachate collection systems to maintain less than 30-cm depth of leachate over liner. Liner systems combine compacted clay and synthetic membranes. Leachate collection piping is sandwiched in a porous layer between liners.
- Operations. Requires exclusion of Hazardous Wastes and bulk or uncontainerized liquid wastes, daily cover and control of disease vectors, methane gas monitoring and control and other air emissions control (i.e., no open burning), access restrictions to prevent illegal dumping, control of precipitation run-on and runoff, and recordkeeping for groundwater monitoring, methane gas, inspection reports, and closure/post-closure plans. No discharges to surface water are permitted.
- Groundwater Monitoring. Monitoring wells required within compliance area. Testing required for 62 pollutants (15 heavy metals and 47 volatile organic chemicals). If pollutants exceed background levels, testing must be conducted for another 245 hazardous inorganic and organic constituents. If specified levels of pollutants found, a corrective action procedure must be initiated.
- Closure and Care. Written closure plan required. Closure include a cap designed to minimize infiltration and erosion, including infiltration layer minimum of 18 inches and permeability no greater than $1x10^{-5}$ cm/sec of material. Care of the facility required for 30 years after closure, including regular inspections for cap integrity and well monitoring.
- Financial Assurance. Must provide detailed estimates of costs for closure and post-closure and to perform corrective action as required; must provide an acceptable mechanism to guarantee funding for these future activities.

In addition to the cost of the modern sanitary landfill, the State of California requires landfills to fund Article V Remediation Costs. Article V regulations require establishment of a fund to cover potential remediation of contaminated groundwater caused by landfills.

The impact of these rules has been to increase the cost per acre of constructing landfills; this, in turn, has resulted in a trend toward development of very large landfills that can keep costs down through the larger volume of waste that can be disposed of at the site. Given the size of these new landfills, there is a parallel trend toward developing new facilities in remote areas with rail or highway access where land is cheaper and large tracts available.

4. Processing

Through the 1970s and 1980s, transformation, or waste-to-energy, facilities were seen as a preferred alternative to increasingly scarce and costly landfill disposal. Facilities financed and built during that period have tip fees in the $30.00 per ton range. As a result of changes in tax law as well as increased air pollution control requirements, tip fees for new facilities would be close to $100.00 per ton.

Trends in recycling markets are discussed in detail in Chapter VII, Section B. There is a present downturn in markets following on the heels of a rapid expansion. As in the case of other commodities, market prices and opportunities for recovered materials will fluctuate; however, it is expected that markets will remain strong as a result of new final market and export market development. The processing costs of materials recovery facilities (MRF) vary among communities and average $50 per ton according to a recent NSWMA study. This includes both the capital costs and the operations and maintenance costs. Revenues from the sale of materials can off-set these costs, depending on the markets.

Unlike other recyclable materials, the markets for yard waste compost products have yet to expand. Processors are producing good material; the problem lies more in learning to present the product in a manner acceptable to the potential major markets (farmers, horticultural firms, etc.). These markets have specific needs and require a proven product. The specifications for compost products derived from waste materials need to reflect the traditional soil amendments used by these markets (e.g., peat moss), so that the user can understand how the compost can be applied to their needs.

APPENDIX F

APPENDIX F. YEAR-BY-YEAR TABLES FOR LANDFILL CAPACITY PROJECTIONS

The following tables provide year-by-year projections of the waste generation and disposal rates for Los Angeles County. The last column in each table, Unsatisfied Need or Daily Disposal Capacity Shortfall, projects the amount of generated waste in excess of the available disposal capacity. The first year a value in the Unsatisfied Need column is greater than zero denotes the "crisis" year, when the quantity of waste generated is larger than the available disposal capacity. As the tables are modified (based on the incremental adjustments discussed in Chapter V, Chapter VI, and Chapter VIII), the "crisis" year is postponed. Ultimately, the solid waste disposal system for Los Angeles County is proven to have much longer useful life than originally projected.

APPENDIX G

APPENDIX G: INTERNATIONAL TECHNOLOGY APPLICATIONS

This Appendix was prepared by Dr. Eugene Grigsby and Dr. Leobardo Estrada, based on information provided by personal contacts supplemented by a literature search. Included in this review are London, England; Hong Kong; and Japan. These international sites display in varying degrees characteristics that make their circumstances applicable to issues in Los Angeles County, including size of population, population densities, economic and social conditions, and level of technical sophistication.

As can be seen from the following writeups, use of landfills is the most common method of municipal solid waste (MSW) disposal. The issue of dwindling disposal capacity is a problem for all three of the locations examined. Recycling is receiving a major push, as is reuse of existing landfills. In Japan, waste-to-energy is a major alternative to the use of landfills. It would appear that London will increasingly turn to waste-to-energy to solve its growing landfill capacity problem. It should also be noted that in Japan a downturn in the economy had a dramatic impact on the volume of waste generation.

Lessons for Los Angeles

1. Economic downturn significantly impacts waste generation. Los Angeles is still in the throes of a recession; therefore, previous projections relative to waste generation are no longer valid.

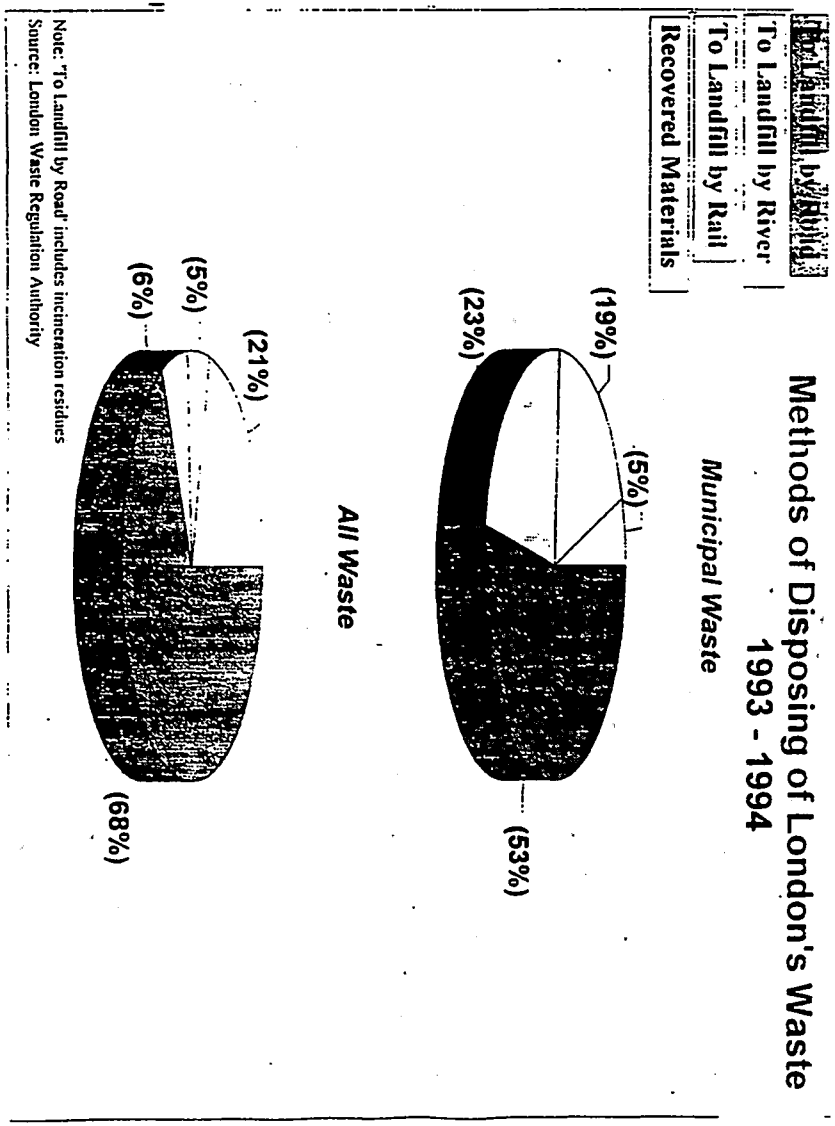
2. Population growth and population composition also directly affect the waste stream. The rate of growth has slowed and the number of lower-income households have increased, thus the previous projections of waste generation are no longer valid. (Note that in Hong Kong, where there are a large number of low-income households, the majority of the waste is from commercial and industrial sources).

3. No world class city has found a single quick, easy solution to solid waste management.

4. Alternatives to utilization of landfill are being strongly encouraged and implemented.

5. Strategies include a combination of reuse of older landfill sites, recycling and waste-to-energy with minimal reliance on landfills.

A. LONDON



The 1995 population of Greater London, England is 6.8 million. The population density in the City of London is 10,429 people per square mile.

Households in London produce on average 1.2 tons of waste per year. The 33 London local authorities collect 3.7 million tons of household and commercial waste annually. The London Waste Regulation Authority (LWRA) is responsible for supervising four statutory waste disposal authorities and three voluntary groups. The LWRA is also responsible for supervising and licensing the disposal of an additional 8.8 million tons of waste handled by private waste disposal companies. The LWRA also has responsibility for regulating the annual disposal of 129,000 tons of hazardous waste. Figure D-1 shows that in 1993-94, 5 percent of the waste was recovered, with the remainder disposed of in landfills.

Approximately 90 percent of London's waste is placed in landfill sites outside of the City's boundaries. According to the LWRA's recently produced report, *Today's Waste, Tomorrow's Resources: The Waste Management Plan for Greater London 1995-2015*, waste disposal in London should be based on a hierarchy of waste management: waste prevention and re-use, waste recycling and energy recovery, and the safe disposal of non-recoverable residues. Increased emphasis is being placed on waste reduction and recycling.

By the year 2000, it is anticipated that 25 percent of all household waste in London will be recycled. However, only 20 percent of the total municipal solid waste stream is anticipated to be recycled in London by the year 2005.

Use of landfills will remain the most viable disposal option, but the Authority recommends that no new landfill sites accepting putrescible waste be permitted. The Authority recognizes that new landfill sites will be difficult to obtain and, therefore, recommends the reuse of existing sites.

Methods of Disposing of London's Waste
1993 - 1994

Fig. 8 G-1

For the last 20 years, London has had only one municipal waste combustion facility. A new waste-to-energy combined heat and power plant is under construction. It is anticipated that construction of additional waste-to-energy facilities will have a significant effect on the need for landfills by reducing each ton of raw waste to approximately 0.30 tons of ash.

B. HONG KONG

Hong Kong has experienced explosive growth in the past. This rate has slowed down, probably due to the impending transfer of government to mainland China in 1996. A population increase of only 5 percent is projected for the years 1991-2000. The 1995 population is 5.8 million, in a total area of 409 square miles (including the New Territories as well as the City of Hong Kong). The population density of the City of Hong Kong is the highest in the world. In 1994, about 3 million tons of municipal solid waste generated from homes, offices and factories ended up in garbage bins. The waste could grow to 4.8 million tons by the year 2006. Composition of Hong Kong MSW is shown in Figure D-2.

Three-quarters of the solid waste and nearly all of the hazardous chemical waste are generated by industry and commerce. Much of this is demolition debris, and the government has initiated a recycling program for this material. However, it is estimated that over half of the waste currently disposed of at landfills could be diverted for land reclamation purposes. Recovery and recycling of reusable materials will also become more attractive as waste producers seek to minimize their waste disposal bills.

The government has embarked on a program to recover costs of waste disposal services directly from the users. Until recently, there has been no fee for disposal at the landfills. The initial scheme for recovering costs, both for landfill disposal and for services provided by the Chemical Waste Treatment Center, is to create economic incentives for waste producers to practice waste management and to exploit waste recycling and reuse opportunities. In addition, Hong Kong is planning several waste-to-energy facilities to supplement their three landfills.

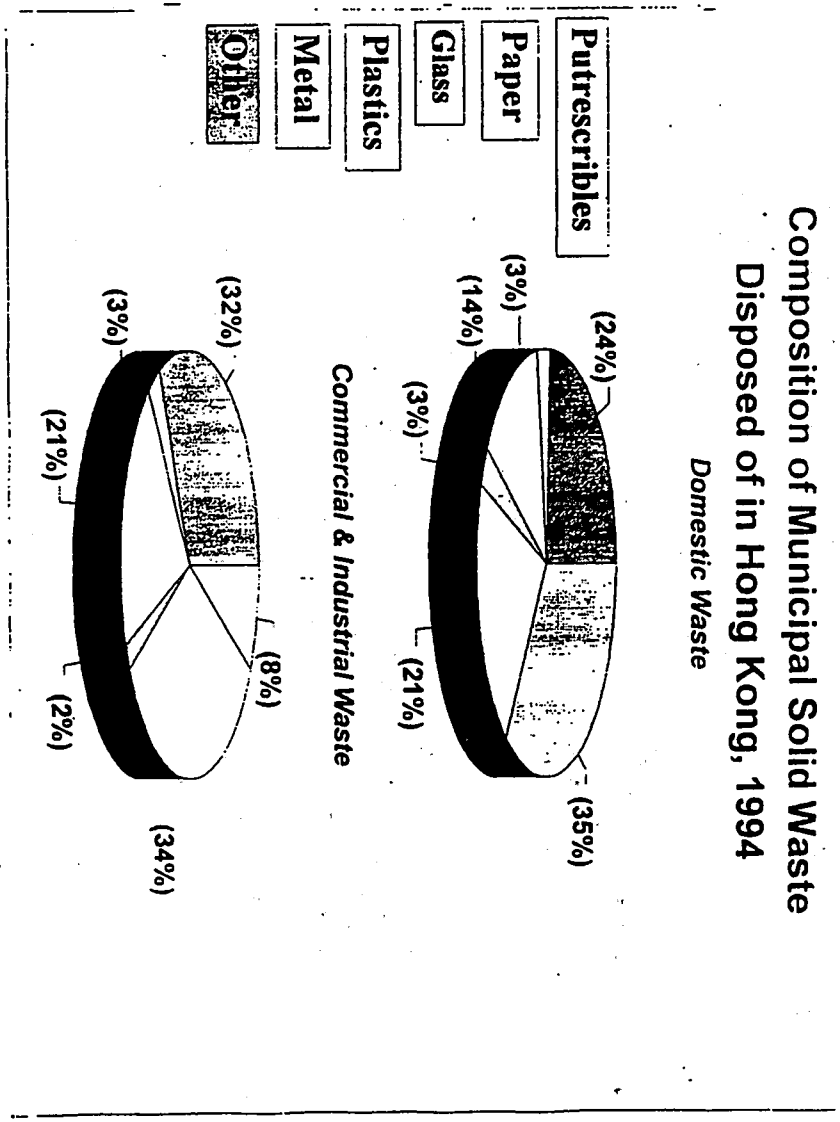


Figure G-2

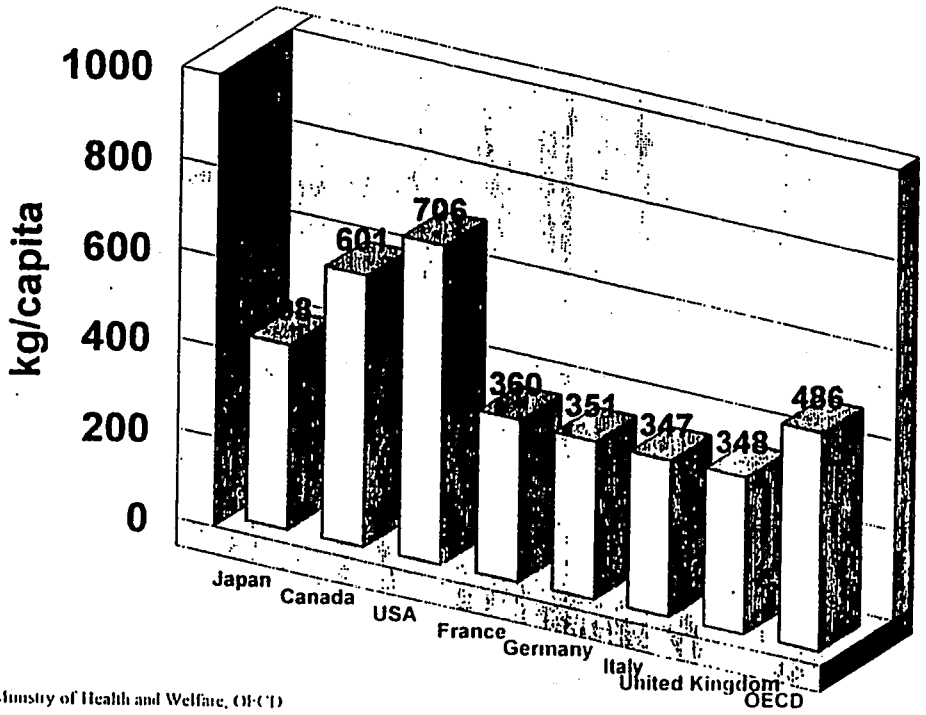
Preliminary findings from a 1994 survey conducted by the Hong Kong Waste Disposal Authority indicates that current recovery and recycling activities in Hong Kong account for 53 percent of the total waste generated by commercial and industrial sectors. This suggests a very significant and robust level of recycling activity. However, the corresponding figure for the domestic sector is only 8 percent.

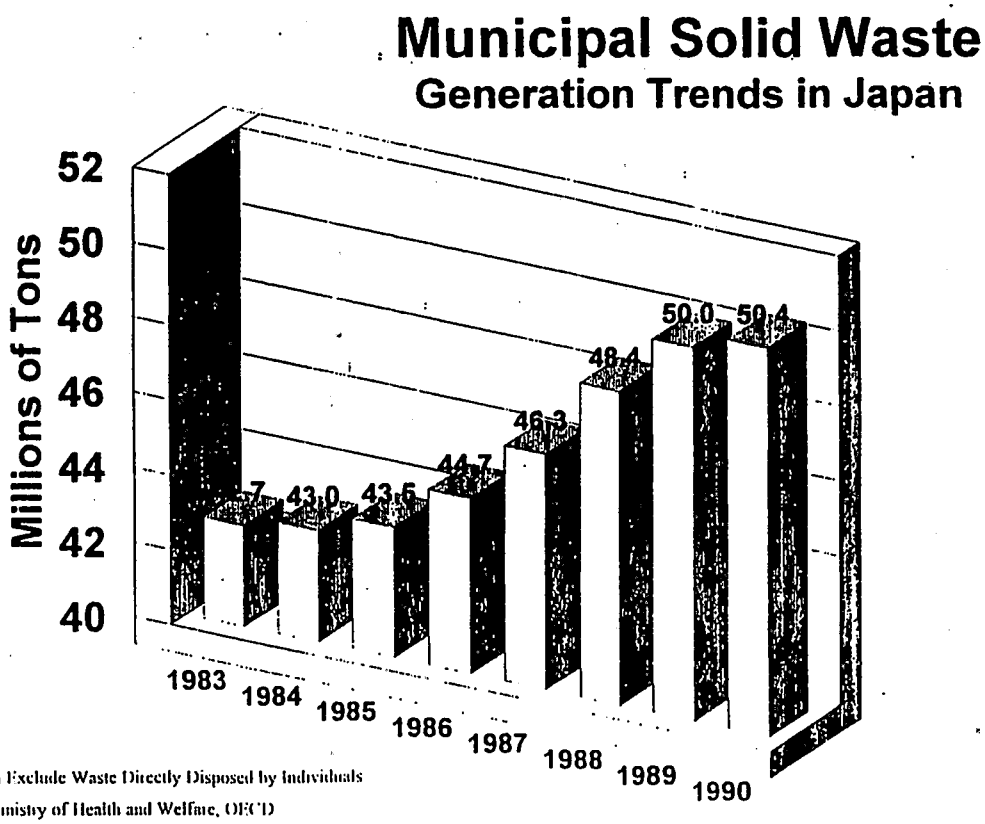
C. JAPAN



The islands of Japan comprise approximately 144,000 square miles, with a population density of 868 persons per square mile. The 1995 population is 125.1 million, of whom 77 percent are residents of urban areas. The amount of MSW generated in Japan increased at a rate of about one percent per year between 1975 and 1985. However, in the following four years, MSW grew nearly four percent annually to reach about 50.4 million tons in 1990. While no national data are available beyond 1990, the Tokyo metropolitan government reports that MSW decreased from a peak of 4.9 million tons in 1989 to 4.7 million tons in 1991. This annual two percent drop is attributed primarily to the economic downturn the country has experienced.

Japanese MSW generation levels per capita compare favorably with those of a number of other Organization for Economic Cooperation and Development (OECD) countries, but the rate of increase in the late 1980s was among the highest in the OECD. Figure D-3 shows per capita waste generation rates for OECD countries in 1990. Much of the growth in MSW generation since 1986 has been in the commercial sector, e.g., copier, telefax and office automation discards. The increase in waste generation from 1985 through 1990 is shown in Figure D-4.

The objectives of Japanese MSW management are:



> "To control the discharge of waste, to perform appropriate waste sorting, storage, collection, transportation, recycling, disposal and so forth, and to cleanse the living environment in order to preserve it and improve public health."
>
> (Reference 1, OECD, p. 52)

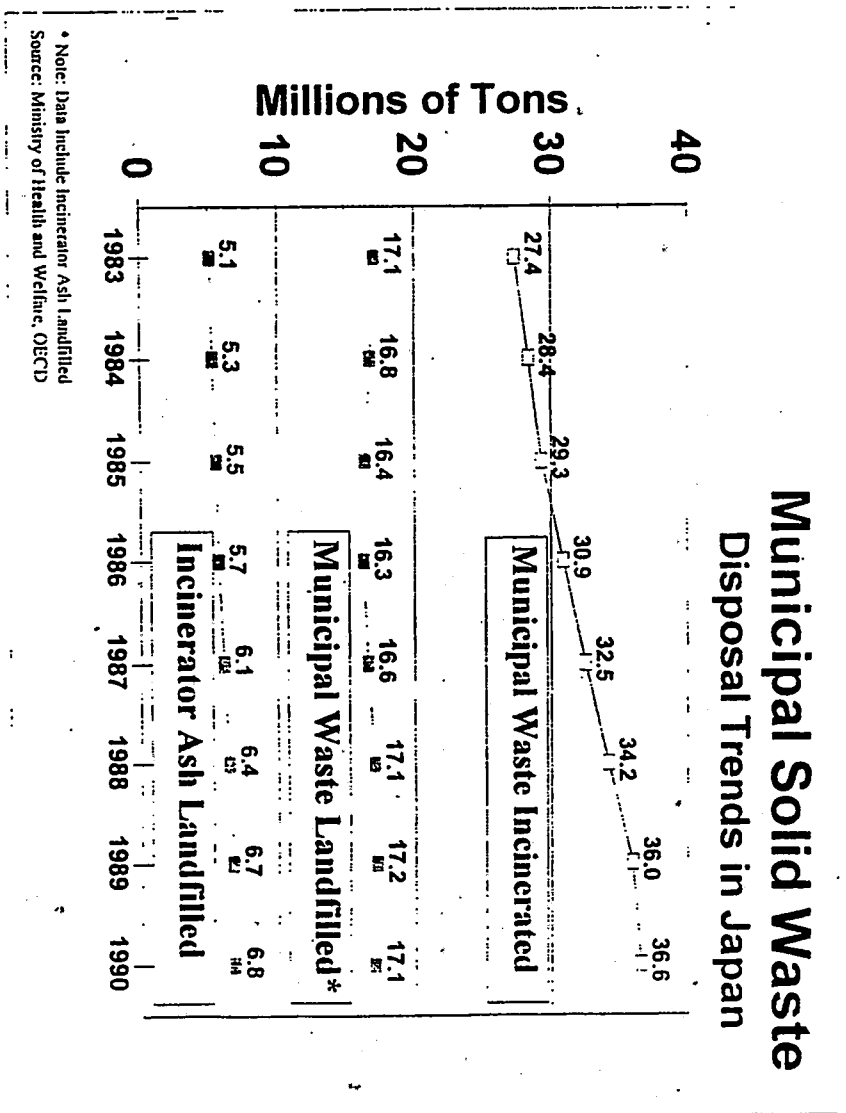
Figure G-4

Note: Data Exclude Waste Directly Disposed by Individuals



Source: Ministry of Health and Welfare, OECD

The Japanese concept of waste reduction is essentially to cut the amount of waste disposed of in or on the land. Waste separated at source for reuse or recycling counts as waste reduction. Since the shortage of landfill capacity is serious, the primary purpose of promoting resource recovery, recycling and reuse in Japan is not to conserve resources or to reduce imports but rather to reduce the amount of waste going to landfill. Disposal trends from 1983 through 1990 are shown on Figure G-5.

Japan's heavy reliance on waste-to-energy can be explained by its objective of avoiding landfill while assuring environmentally sound disposal. About 75 percent of MSW is combusted. Combustion reduces the mass of MSW by roughly 82 per cent and its volume by over 95 per cent. Since the ash is landfilled along with untreated MSW, and landfill life depends on volume, the ash represents a relatively small burden on national landfill capacity. Japan has addressed some of the issues related to siting by operating extremely clean facilities equipped with state-of-the-art emission controls. Also, the plants are aesthetically designed and co-located with desirable land uses such as recreation centers and swimming pools.

Current landfill capacity for MSW is expected to be exhausted before the turn of the century. Capacity shortage has led to illegal dumping of MSW and industrial waste. Because of this illegal dumping problem, Japan has decided that 84 percent of MSW must be processed for reduction through waste-to-energy or crushing by March 1996. This will mean adding seven million tons per year of waste-to-energy capacity over the next three years. In addition, the Japanese are building industrial waste treatment plants and night soil and septic tank sludge facilities.

APPENDIX H

APPENDIX H: TABLES AND METHODOLOGY USED FOR DIVERSION RATE CALCULATIONS

The annual diversion rates for Los Angeles County were projected by identifying the composition of the waste stream and the individual diversion rate for each waste component. The waste steam composition for each generating sector (residential, commercial, and industrial), which is shown as Table H-2, was taken from the *Source Reduction and Recycling Element for Unincorporated Los Angeles County* (County of Los Angeles Department of Public Works, December 1991).

The anticipated diversion rate for each component of the waste stream is based on three levels of recycling effort. The diversion rates associated with each of the levels (and for each generating sector) is shown as Table HG-3. The various levels of recycling intensity are discussed in detail in Chapter VII. The current diversion rate, Level 1, is based on the current recycling effort. The individual diversion rates for each waste component are typical diversion rates experienced by other communities and are based on the overall diversion. Levels 2 and 3, which are anticipated to be reached in years 2000 and 2005 respectively, represent incremental increases in the intensity of recycling efforts. Similar to Level 1, Levels 2 and 3 represent typical diversion rates experienced by other communities at equivalent recycling levels of intensity.

Table H-1 shows the projected annual diversion rates for Los Angeles County. The first step in identifying the diversion rates is dividing the total waste stream into the three major generating sectors, residential, commercial, industrial. The percentages for each sector were taken from the *Source Reduction and Recycling Element for Unincorporated Los Angeles County* (SRRE). The SRRE includes a miscellaneous sector, which generates 3.2 percent of waste stream. This 3.2 percent was divided into prorated fractions and added to the residential, commercial, and industrial sectors. For the purpose of diversion rate estimates, the percentage of waste generation allocated to the residential, commercial, and industrial sector were 50.6, 32.3, and 17.0 respectively.

After the total waste stream is divided into the three generating sectors, which are shown as the third, fourth, and fifth column of Table H-1, the waste from each generating sector is multiplied by the composition percentages from Table H-2. The annual generation of each waste component (for each generating sector) are listed in Appendix Tables H-4 through G-18. Adjacent to each generation rate is the diversion rate, taken from Table H-3. The diversion rates are assumed to increase linearly between the different Levels of recycling intensity.

For each year in Tables H-4 through H-18, the generation of each waste component is multiplied by the respective diversion rate. The summation of these products is total amount of waste recovered from the generating sector. The annual amount of recovered waste is shown in the last column of Tables H-8 (residential), G-13 (commercial), and G-18 (industrial). These values are also included in Table H-1 and a corresponding diversion rate by generating sector is provided. The recovered wastes from each generating sector are added together in the second to last column in Table H-1. Dividing this value by the total waste generation rate provides the annual percent diversion rate.

APPENDIX I

APPENDIX I: COST ISSUES

This Appendix discusses some of the cost issues relevant to integrated solid waste management planning. It is not possible to develop a detailed cost plan for the recommendations made in the report. To do so would require obtaining present cost data from the County and the County Sanitation Districts of Los Angeles County, as well as from each of the Cities in the County.

Determining the actual cost of solid waste management is one of the most difficult tasks encountered by communities developing integrated solid waste management plans. Many costs, particularly overhead costs such as personnel management, are handled by separate departments. The amount of time allocated to management of solid waste personnel must be estimated as part of the overall cost of solid waste. In addition, divisions often share equipment, marshalling yards or supervisory personnel, or pitch in together to provide emergency services, making it difficult to identify solid waste-specific costs.

The objective in this Appendix is to get the County thinking about how to develop a coherent integrated solid waste management system and help communities control costs. The County can function in a key coordinating role. This does not mean that the County shoulders all costs or manages all facilities; it means that the County actively supports the Cities and facilitates their operations. Elaborate solid waste systems can be very costly if program components are added piecemeal. County leadership can be critical in this area through:

- preparing the County Comprehensive Plan to coordinate efforts between the various County jurisdictions or provides joint City/County-sponsored facilities;
- developing facilities that serve multiple jurisdictions (e.g., transfer stations) that, through economies of scale, keep costs down despite possible longer haul distances;
- developing County model programs, including a variable rate fee system for County-collected areas and technology demonstration programs for landfill operations (see Chapter IX.F); and

- maintaining the economic viability of existing facilities, for example, through waste transfer to the WTE facilities (Chapter IX.H) or developing a policy of purchasing supplies from recycling enterprises ("Buy Recycled") that utilize recyclables collected in Los Angeles County.

In addition to the coordinating role, the County can pioneer some innovative ways of financing solid waste management programs that also foster diversion of waste from disposal, including: enterprise fund accounting, and variable rate fees ("unit pricing"). Also discussed in this Appendix are the relative share of the solid waste dollar cost for different system components, and factors influencing costs. These two topics provide background for Report discussions.

A. ENTERPRISE FUNDS

Operating an integrated solid waste management system as an enterprise fund allows communities to track the true cost of service, and keeps the funding for services separate from the political vagaries of the government budgeting process. In an enterprise fund, all revenues and costs go to a cost center. Revenues do not go to the General Fund, debt service is not paid for by Finance, benefits by Personnel, or fuel by the Transportation Department, etc., which is often the case when solid waste is part of a jurisdiction's operation. Future post-closure costs and sinking funds are established in enterprise accounting, and it possible to tell the cost for solid waste service and charge for it -- by the ton, by the household, by the business address, etc.

B. VARIABLE RATES

Local governments need to find ways to charge the generator for the service received in order to get solid waste costs out of the General Fund. Direct billing of customers for the solid waste service received is a key component of enterprise fund accounting. These fees, plus other revenues such as from the sale of recovered materials, make up the funds used to pay costs. Generator billing should be done in a way that encourages source reduction as well as maximizes diversion. A variable rate system (also called "unit pricing") goes far to accomplish this and

is also an important part of enterprise accounting for solid waste management. Variable rate pricing has been the norm in commercial collection for years -- the generator is billed based either on the weight of the material collected by the hauler, or by the size of the waste storage container used by the generator. For the residential customer, it can mean higher costs for more waste, or lower costs for less waste and more recycling. For the commercial generator, it can mean differential fees (or no fee) for loads that can be recycled. As consumerism is applied to solid waste services, the generator will have incentive to dispose of less and to set aside more materials for recycling. An example of a variable rate fee system is provided in Appendix A, Case Study of the City of Seattle.

C. COSTS FOR SOLID WASTE SERVICES

The solid waste dollar goes to many functions, depending upon the make-up of the specific system. Shown in Figure I-1 is a pie chart, developed from data from several cities, that graphically portrays how the solid waste dollar is split up. Administrative costs for each of the components are included in each portion of the pie. As can be seen, collection-related costs comprise over 60 percent of the pie, followed by disposal at 30 percent, and lastly by processing at 8 percent. It should be noted that solid waste collection includes bulk waste and special collections (such as post-special event collections and disaster debris), while recycling collection costs include yard waste collection as well as curbside service for materials. The pie chart shows recycling-related collection costs at 20 percent -- or almost one-third of the collection expenditures. Recycling costs overall can represent over one-quarter of the way the solid waste dollar is spent.

In addition to the above service-related and direct administrative costs, a community can expend considerable funds on specialized services, such as Household Hazardous Waste (HHW) collection and public information campaigns to encourage recycling and HHW diversion. Many communities have turned to surcharges on landfill or transfer station tipping fees as a means of funding new diversion programs, particularly for programs such as HHW that have a high unit cost and do not produce revenues to help pay for the program. Monies collected through surcharges can "get lost" in the General Fund; enterprise fund accounting can keep these

resources dedicated to solid waste management programs.

D. FACTORS INFLUENCING COSTS

Trends that influence recycling and solid waste disposal costs are discussed in various Report Chapters, and are summarized here by the service component. Overall, the cost of solid waste management is rising, but offsetting trends are discussed as well.

1. Collection

Two factors are driving the cost of solid waste collection. First, obtaining high-quality recyclables from the waste stream often means curbside collection of source-separated designated materials. This adds specialized recycling collection trucks and personnel routed through the same neighborhoods as the solid waste collection packer trucks. Yard wastes are also collected through a separate route system. Bulk wastes may also be collected separately using open-bed trucks equipped with a grapple. Each additional collection system will increase the number of trucks and personnel needed to get the job done.

Second, as the solid waste management system has evolved, the equipment industry has been evolving along with it. Automated collection equipment allows a single driver to complete a route, rather than the two- or three-man crews required for traditional packer trucks. Sophisticated routing software and GIS mapping allow a jurisdiction to consolidate routes, so that as recycling collection expands, solid waste collection routes can be adjusted proportionally, and optimum routes (i.e., the most material in the least time) can be devised for each type of collection. Other equipment features, such as split packers, allow a single truck to perform double duty while on a route. These options can be used to reduce the cost of collection.

Communities are innovating to contain the costs resulting from these trends. Automated collection has been applied to recyclable materials as well as refuse. Rebanco in Seattle has utilized authomated recycling collection in 96 gallon carts and reduced the collection frequency to once per month. Guelph, Ontario is implementing wet/dry collection citywide in the city,

with a population of 80,000. This followed an extensive pilot program to establish the cost and effectiveness of the program. Because the collection function represents a majority of the solid waste management cost, efficiency in this area has the largest reduction in overall cost for the investment.

2. Transfer

Collection costs can also be contained by adding transfer station(s) to the system. As discussed in Chapter IX, transfer stations can reduce collection costs by keeping collection packer truck routes as short as possible (less than 30 miles). A transfer trailer can carry three times the amount of waste as a packer truck and rail cars can carry six times the amount. Shifting the waste to larger-capacity, more efficient transfer vehicles for transport to the disposal site reduces the number of personnel and vehicles needed.

Even though transfer operations add capital and operations costs for transfer stations and vehicles, they have the potential to significantly reduce the overall cost. The reduction in the non-productive time for the route collection trucks has a double pay-off. First, the cost per collection route is reduced and second, the route collection trucks can collect from additional routes. This lowers the investment in trucks and crews.

3. Solid Waste Disposal

Class III Sanitary Landfills are still the primary method of managing solid waste in Los Angeles County. The cost of landfill disposal is a political issue as well as a technical one. The true cost of local landfill disposal is not reflected in $20.00 per ton tipping fees. Some long-term costs of landfill disposal can be deferred (rather than paid out of tipping fees), particularly closure, post-closure, and Title V Remediation Funds, plus, for existing landfills, the cost of the site may have already been paid for and does not reflect current land values. However, a jurisdiction may choose to keep landfill prices low in order to keep waste from leaving to lower-cost disposal sites in order to maintain cash flow at the landfill, or (as in the

case of Orange or Riverside Counties) may reduce the price to attract waste from outside the jurisdiction and thus increase cash flow in the short term.

The actual cost of landfill disposal is driven by the cost of the land, pre-development costs for planning and permitting, plus the construction and operation costs of the facility over its life. The U.S. EPA promulgated new rules for landfill management on October 9, 1991. These rules, as subsequently adopted by the State of California, set standards for:

- Location. Includes limits on proximity to airports, 100-year floodplains, wetlands, fault areas, seismic impact areas, and unstable areas.
- Design. Requires composite liner and leachate collection systems to maintain less than 30-cm depth of leachate over liner. Liner systems combine compacted clay and synthetic membranes. Leachate collection piping is sandwiched in a porous layer between liners.
- Operations. Requires exclusion of Hazardous Wastes and bulk or uncontainerized liquid wastes, daily cover and control of disease vectors, methane gas monitoring and control and other air emissions control (i.e., no open burning), access restrictions to prevent illegal dumping, control of precipitation run-on and runoff, and recordkeeping for groundwater monitoring, methane gas, inspection reports, and closure/post-closure plans. No discharges to surface water are permitted.
- Groundwater Monitoring. Monitoring wells required within compliance area. Testing required for 62 pollutants (15 heavy metals and 47 volatile organic chemicals). If pollutants exceed background levels, testing must be conducted for another 245 hazardous inorganic and organic constituents. If specified levels of pollutants found, a corrective action procedure must be initiated.
- Closure and Care. Written closure plan required. Closure include a cap designed to minimize infiltration and erosion, including infiltration layer minimum of 18 inches and permeability no greater than $1x10^{-5}$ cm/sec of material. Care of the facility required for 30 years after closure, including regular inspections for cap integrity and well monitoring.
- Financial Assurance. Must provide detailed estimates of costs for closure and post-closure and to perform corrective action as required; must provide an acceptable mechanism to guarantee funding for these future activities.

In addition to the cost of the modern sanitary landfill, the State of California requires landfills to fund Article V Remediation Costs. Article V regulations require establishment of a fund to cover potential remediation of contaminated groundwater caused by landfills.

The impact of these rules has been to increase the cost per acre of constructing landfills: this, in turn, has resulted in a trend toward development of very large landfills that can keep costs down through the larger volume of waste that can be disposed of at the site. Given the size of these new landfills, there is a parallel trend toward developing new facilities in remote areas with rail or highway access where land is cheaper and large tracts available.

4. Processing

Through the 1970s and 1980s, transformation, or waste-to-energy, facilities were seen as a preferred alternative to increasingly scarce and costly landfill disposal. Facilities financed and built during that period have tip fees in the $30.00 per ton range. As a result of changes in tax law as well as increased air pollution control requirements, tip fees for new facilities would be close to $100.00 per ton.

Trends in recycling markets are discussed in detail in Chapter VII, Section B. There is a present downturn in markets following on the heels of a rapid expansion. As in the case of other commodities, market prices and opportunities for recovered materials will fluctuate; however, it is expected that markets will remain strong as a result of new final market and export market development. The processing costs of materials recovery facilities (MRF) vary among communities and average $50 per ton according to a recent NSWMA study. This includes both the capital costs and the operations and maintenance costs. Revenues from the sale of materials can off-set these costs, depending on the markets.

Unlike other recyclable materials, the markets for yard waste compost products have yet to expand. Processors are producing good material; the problem lies more in learning to present the product in a manner acceptable to the potential major markets (farmers, horticultural firms, etc.). These markets have specific needs and require a proven product. The specifications for

compost products derived from waste materials need to reflect the traditional soil amendments used by these markets (e.g., peat moss), so that the user can understand how the compost can be applied to their needs.

APPENDIX J

APPENDIX J: RECYCLING MARKETS

There are two types of markets available for all classes of recyclable materials: intermediate and final markets. The category of intermediate markets includes processors of scrap material and brokers of recyclable materials. Final markets (also called end-users) encompass the utilization of materials in the manufacture of new products in industrial plants or mills. Final markets are the last step in the recycling process. As described below, there is a lot of overlap in the functions performed by these markets.

Materials recovered from the municipal solid waste stream need upgrading in order to be marketed as raw materials to manufacturing industries. This upgrade processing step is usually carried out by an intermediate at the local level. Intermediate markets include scrap processors, materials recovery facilities (MRFs) and brokers. Materials recovery facilities may be publicly or privately owned, and generally accept source separated recyclables collected from households through drop-off or curbside collection programs. A scrap processor generally purchases a wide variety of scrap materials from industrial, commercial, and private sources. These two types of processing facilities are collectively referred to as scrap processors in this discussion. When a processor has enough of a particular material, the material is processed to final market specifications and then is transported to market. By contrast, a scrap broker arranges the final market destination of the processed goods -- a scrap broker may never see the material that is bought and sold. A scrap processor may serve as both processor and broker. The materials upgrade is but one service that the intermediate markets provide; they may also furnish storage containers, pickup for filled containers, and provide delivery of processed materials to the final market. The cost of these intermediate services is included in the price that is charged to the final market for the goods.

The final market manufactures products from the purchased recyclable materials. Usually a final market will accept only one type of material, but some final markets are now purchasing multiple materials -- processing some for their own use and acting as intermediate markets for others. Final markets generally pay higher prices for recyclable materials than do intermediate markets because final markets often rely on intermediate markets to process needed materials

for conformity to higher standards of acceptability. Although one cannot overlook the services that the intermediate market can provide, the price paid for goods by the final market is often sufficiently higher than that paid by the intermediate market to warrant bypassing the latter and selling recyclables directly to the final market. Also, in some situations, final markets are more easily accessed than intermediate markets.

1. Specifications and Agreements

Each material marketed or sold has a description or specification so that the buyer knows what is to be received. While many markets or firms have their own specifications, industry groups such as the Institute of Scrap Recycling Industries (ISRI) publish specifications that are widely accepted. Specifications address issues such as (1) allowable levels of contaminants, (2) moisture content, and (3) shipping preparation (for example, baled with a specific density). Specifications, when utilized in good faith, allow both the buyer and seller to agree on the quality of the commodity without a detailed inspection of every shipment.

The development of specifications for recovered materials has paralleled the expansion of the recycling industry. Secondary or recovered materials have grown into major domestic and international trade elements. This growth makes it impractical, if not impossible, for buyer and seller to do business on a personal basis. In the last 20 years, the amount of secondary paper consumed has doubled, resulting in more paper recovered in 1993 than was landfilled. The volume of market purchases and the standardization of these purchases, through specifications and contracts, has routinized transactions. This maturation of the secondary materials market encouraged the Chicago Board of Trade to establish trading in 1995 of recovered materials in a manner similar to virgin materials commodity trading. At the same time, procedures and protocols to deal with discrepancies in weight, quality and schedule have developed. ISRI and the Chicago Board of Trade through the American Arbitration Association, offer arbitration services to resolve disputes, as do other entities.

To avoid the fluctuations of commodities markets and the costs of small lot trading, many communities or their private recycler enter into contracts for the sale of materials over several

years. The terms of these agreements vary from one to twenty years; however, five-year contracts are common. When a contract requires one party to construct a facility to process material (such as a publicly-procured materials recovery facility), the contract term is tied to the facility life or amortization period, usually 15 to 20 years.

The price in these long-term contracts is usually adjusted using one of the recognized publishers of price data. *Official Board Markets* and *Recycling Times* are two major publishers of price data. In the last several years, the number of materials recovered from MSW quoted in these publications have grown along with the markets.

2. Processing Facilities

Whether source separated or not, material collected from waste generators needs to be processed to meet market specifications. The functions a processing facility performs are: (1) receiving, (2) storage, (3) separation, (4) cleaning, (5) size reduction, (6) densification, and (7) shipping preparation. These functions usually are contained in an industrial/warehouse type of building and include both mechanical and manual techniques. The choice of processing depends upon: materials processed, amount of material, and specifications or requirements of the markets.

The sponsorship, ownership, and operation of processing facilities can be either public or private, depending upon community situations. Prior to the recent push for recycling, processing was primarily done by private firms in the traditional secondary materials industry. These firms performed the processing necessary to prepare materials such as glass, paper, aluminum, and steel for use by industry.

When the aluminum can was introduced as a beverage container almost 20 years ago, the aluminum industry made a commitment to recycle these cans. The industry built a separate infrastructure, including: (1) collection points, (2) trucks, (3) processing facilities and (4) smelter modifications. This infrastructure cost of millions of dollars, and resulted in a current recycling rate of 65 percent.

Traditional scrap processors and the aluminum can recycling industry are only a part of the overall recycling business. The infrastructure necessary to recycle greater quantities and types of materials will require billions of dollars of investment. Processing facilities for 50 percent of the solid waste generated in Los Angeles County in 1994 (not counting yard waste) would process approximately seven million tons of material. A facility processing materials at the rate of 200 tons per day would cost about $2 to $8 million in the Los Angeles region. To have sufficient capacity using 200 TPD plants operating six days per week, 112 plants would be required. This requirement, based upon the $6 million capital cost, would involve an investment of $225 to $900 million. This is a lot of recycling infrastructure; some of which has been constructed. Sufficient capacity does not yet exist in Los Angeles County.

In addition to general processing facilities, infrastructure investment is needed for each of the recovered materials discussed below.

3. Recyclable Materials

a. Paper

Five types of paper are considered in this section: (1) old newsprint (ONP), (2) old corrugated containers (OCC), (3) printing and office paper (POP), (4) old magazines (OMG) and (5) mixed papers.

According to the American Forest & Paper Association, in 1995 more than 42 million tons of paper were recovered in the United States, with almost 33 million tons of that total recycled into new products in the U.S. Another 10 million tons was exported. Recovery has risen every year since 1985, doubling in this decade.

The major source of ONP is individual homes. ONP is used primarily in the manufacture of newsprint and paperboard. These represent 34 and 22 percent demand respectively. A small percentage of ONP is used in making tissue, cellulose insulation, and other products. Seventeen percent of ONP is exported. Demand has slackened in the last six

months due to high inventories and lower exports. A level period is expected in the immediate future.

The majority of old corrugated cardboard (OCC) ends its useful life at retail, wholesale, and industrial establishments, with a lesser portion discarded in individual homes. OCC is the most commonly recycled paper product, with 78 percent used in the manufacture of new containerboard and paperboard products. Fifteen percent of OCC is exported.

Printing and Office Paper (POP), which has the highest value of all postconsumer paper, is generated primarily in commercial offices such as financial institutions and large insurance groups. Government offices also generate considerable amounts of POP. While POP is present in the home, it is usually generated in much smaller quantities and is difficult to separate from lower value paper, such as envelopes. Twenty-eight percent of recycled POP is used in the manufacture of tissue paper (i.e., bathroom and facial tissue, towels, and napkins), with 26 percent used for writing, duplicating, and computer papers. Twenty percent of POP is exported.

The demand for the lower grades of paper -- ONP and OCC -- has historically fluctuated widely. Because so much recycled paper is used in paperboard production and construction (i.e., wallboard and insulation), when the construction industry declines or the economy is weak, the demand for and price of low-grade paper falls. Conversely, when housing construction improves and the economy is sound, demand and prices for lower grades of paper typically are strong. Because its primary end use is in basic consumer products (e.g., writing paper and tissue) the demand and price for POP is steadier and higher than for the lower grades.

As discussed below, paper manufacturers have added pulping capacity to utilize recovered paper as feedstock. This increased capacity for utilizing recovered paper has increased demand; domestic mill consumption of recovered paper rose 8 percent in 1995. Mixed paper can be recovered from both residential and commercial generators. In the last two years, there has been a trend toward recovering mixed paper from residences. In addition, the newest technology for de-inking ONP requires the use of up to 20 percent coated papers (i.e., old magazines or OMG), which has, in turn, created a market for this type of recovered paper.

Along with the growth in paper recycling has been an investment by the paper industry in plants to process recovered paper. Currently, more than 200 paper plants in the U.S. use 100 percent recovered paper as their feedstock. Another 175 plants depend upon recovered paper for a portion of their feed. Development of pulping facilities for recovered paper feedstock has involved a multi-billion investment in industrial infrastructure to date; this investment is continuing. The prices for all grades of paper rose sharply in 1995 as the result of the demand created by these new pulping plants. These prices peaked in mid-summer, then dropped due to high inventories and poor demand. The investment in new plants will prevent demand and prices from falling to 1990 levels.

b. Glass

Glass is manufactured primarily from sand and silicon dioxide. Other materials used in glass manufacturing include sodium, soda ash, and calcium from limestone. Glass manufacturers produce three categories of products: containers, flat glass, and pressed/blown glass. Glass containers account for 70 percent of all the glass manufactured and make up approximately 90 percent of the glass in municipal solid waste (MSW). Flat glass is used mainly for windows. Pressed and blown glass includes ornamental and decorative glass and other glass products such as light bulbs. These three types of glass have different chemistries and cannot be melted together to make new products. Only container glass is pertinent to this discussion. Container glass represented approximately 3.0 percent of the waste stream in Los Angeles in 1990.

Glass containers are manufactured primarily in three colors: clear (flint), brown (amber), and green. Nationally, approximately 65 to 70 percent of all containers are flint, and roughly equal amounts (15 to 18 percent) of glass containers are amber or green. Thus, the demand for recovered flint container glass is greater than the demand for either amber or green.

The glass industry uses waste glass (known as cullet) as an alternative to raw materials. Before 1970, almost all cullet used in the manufacturing process was from "in house" sources. Since 1970, when only 24,000 tons of cullet were purchased by the glass industry, cullet use from private and municipal recycling has increased to more than one million tons annually. In

1981, the price paid for cullet was generally consistent around the country, averaging about $30 per ton. By 1983, the price rose to $40 per ton and remained steady until the latter half of 1988. Since then, the price has varied with more differences among regions and by glass color. In 1995, the prices were approximately $50 per ton for flint, $40 per ton for brown, and $20 per ton for green glass. Glass prices dropped somewhat over the course of 1995, due to lagging demand.

With today's glass-processing technology, it is possible to use nearly 100 percent cullet in glass furnaces. This increased use of cullet is advantageous because cullet melts at a lower temperature than the raw materials, allowing the glass manufacturer to save energy. Also, lower furnace temperatures prolong furnace refractory life. However, while glass container recycling has been increasing, the recycling rate for 1994 was only 37 percent.

Glass has been declining as a fraction of the waste stream due to its replacement by plastic, aluminum and other containers. Low prices, low market demand for green glass in particular, and problems with glass contamination of other recyclables during collection, coupled with stringent specifications for furnace-ready cullet caused some communities to drop glass from their recycling programs. Other communities have maintained glass recycling and are marketing a mixed broken glass for lower-value uses such as aggregate and filter sands.

c. Ferrous Metals

In recent years, the market demand for ferrous metals (i.e., steel and iron) scrap has fluctuated, but has generally been rising. However, prices have fluctuated with no real pattern. The problems in steel scrap markets are linked to the decline in U.S. steel-production capacity. According to *Phoenix Quarterly*, U.S. steel production capacity peaked in 1977 at 160 million net tons. Production capacity dropped to 110 million metric tons in the mid-1980s. The Institute of Scrap Recycling Industries (ISRI) believes several factors contributed to the elimination of U.S. steel production capacity, including an oversupply of the market by foreign government-controlled steel producers and decreased demand for steel products. Offsetting this market decline to some extent is increased application of electric furnace technology and the

"mini mill" in the U.S. These smelters use a higher percentage (up to 100 percent) steel scrap as feedstock. Also, the export market has been strong.

Most of the ferrous metal in residential MSW falls into two categories: bulky ferrous (e.g., appliances) and container ferrous (e.g., food and beverage cans). There are actually two types of steel cans in residential MSW: bi-metal cans, made of a steel body and aluminum top; and "all" steel cans. The all steel cans also have two types: "tin" cans that are steel coated with a layer of tin to retard rusting, and tin-free cans. Bi-metal cans used in beverage applications largely have been replaced by aluminum cans. In the past, container ferrous was regarded as a low-quality product, and was not a primary target for recycling programs. However, the Steel Recycling Institute recently began promoting the recyclability of bi-metal and steel cans (including aerosol and paint cans), noting that the cans may go directly into existing furnaces with no special pre-processing.

The detinning industry processes "tin" cans and other tin-plated scrap to chemically remove the tin, then selling both the tin and steel to end-user markets. In the past, this industry was a major market for ferrous cans. Today, only one detinning processor remains in the U.S. and the long-term outlook is pessimistic due to the declining use of tin.

Ferrous metals, except major appliances, represent about 3.3 percent of the Los Angeles County waste stream in 1990. Prices recorded for steel cans from January through October 1995 were steady between $63 and $65 per ton. Note that steel is traded in long tons which weigh 2,240 pounds.

Appliances and other large steel items in municipal waste are referred to as white goods. These can be shredded along with automobiles to produce a high quality scrap. The market, therefore, is the traditional scrap processor with large-scale shredding equipment. Some white goods made prior to 1979 have capacitors containing PCBs. Most scrap processors insist that these capacitors be removed prior to their acceptance at processing facilities. Additionally, chlorofluorocarbons (such as freon) used as refrigerants in some appliances need to be removed and recycled or disposed of properly, rather than vented to the atmosphere. Some jurisdictions

have contracted for removal of PCBs and chlorofluorocarbons, processing and marketing with a single contractor. When white goods are shredded along with automobiles, the resulting scrap sells for $40.00 to 60.00 per ton more than ferrous can scrap on the west coast.

d. Aluminum

Aluminum, found in a variety of mineral structures, is recovered primarily from bauxite, an ore found principally in South America, Africa, and the Caribbean. Sources of bauxite within the United States are found in Alabama, Arkansas, and Georgia. Extraction of aluminum from bauxite requires a large amount of electricity. Aluminum in municipal waste is found in several forms or alloys: food container aluminum (cans and foil); aluminum housewares (e.g., pots, pans, and appliances); extrusions (e.g., lawn furniture); and castings (e.g., auto parts and more expensive cooking equipment). Food container aluminum, particularly aluminum cans, has the highest market value because the alloy from which it is made is almost pure aluminum.

Aluminum has a high value for its weight. However, it represents only a minor fraction of MSW. The 1990 solid waste composition in Los Angeles County indicates that aluminum cans were 0.6 percent of the waste stream.

In the 1970s, the U.S. aluminum industry turned to recycling as a major source of material. According to the Aluminum Association, almost 25 percent of all the aluminum used in the United States in 1988 came from recycled aluminum. The recycling rate of aluminum cans in 1990 was 61 percent, and the rate rose to 65.4 percent in 1994. The U.S. aluminum industry, particularly corporations such as Alcoa, Reynolds Metals, Alcan, and Kaiser, strongly supports aluminum recycling and has made significant investment in recycling infrastructure over the last two decades. It is estimated that there are 10,000 individual aluminum recycling facilities in the U.S. Firms in the industry actively are seeking other aluminum alloys in addition to cans in order to increase recycling.

There have been recent variations in prices paid in the Western states by processors and end-users for aluminum used beverage containers since 1990. The drop in price between 1992

and 1995 reflects the dumping of aluminum on the world market by the Russians in an effort to gain hard currency. This highlights the impact of international events upon U.S. recycling markets. These events are both normal and unpredictable. The price at the end users peaked in January 1995 at over $1.400 per ton and dropped to approximately $1.200 on the west coast in December.

e. Plastics

There are six plastic resin types typically found in MSW: high density polyethylene (HDPE), low-density polyethylene (LDPE), polyethylene terephthalate (PET), polyvinyl chloride (PVC), polypropylene (PP), and polystyrene (PE). These and other resin types can be recycled into a variety of products, including fiberfill for pillows, sleeping bags, jackets, etc.; molded products such as tubs, bins and shower stalls; and lumber-like products for vehicle stops, park benches, dock pilings, etc.

In Los Angeles County, plastic was a small, but increasing, portion of the 1990 solid waste stream. Nationally, plastic rose from less than one percent of MSW in 1960 to 6.9 percent in 1990 by weight. By volume, plastics are a higher proportion of the waste stream, esumated at roughly 10 percent. Because recovered plastic is a lightweight, high-volume material, it requires more storage space and has higher transportation costs than higher-density recyclable commodities. For example, two-liter PET soda bottles contain entrapped air; as a result, they take up a great amount of space (the density is 1.3 pounds per cubic foot) and are difficult to compact. Plastic that has been shredded or punctured and baled can be transported much more economically; for example, shredded PET density is 25 pounds per cubic foot. In 1990, approximately 1.2 percent of the Los Angeles County solid waste stream was composed of recoverable HDPE or PET containers. These two resins most commonly are included in recycling programs and have been increasingly recycled. PET soft drink container and HDPE natural containers were recycled at 48.6 and 25.9 percent respectively in 1994. Other plastics are recycled significantly less.

HDPE prices have fluctuated widely in the past two years, peaking in March 1995 at $0.28 per pound. The recent trend has been downward, due to rising inventories and weak worldwide demand resulting from reductions in the use of recycled HDPE in products. HDPE prices were approximately $0.12 per pound in December 1995. PET prices have risen in 1995 from about $0.08 to $0.25 per pound. PET prices have been much more stable, in major part because of demand in the Far East market and due to increased use of PET in food packaging. Poor cotton harvests have contributed to this demand (PET competes with cotton in many fiber applications).

In spite of the constraints in collecting postconsumer plastics from the residential waste stream, there is a growing interest in recycling this material for social and environmental reasons. Fueled by this trend, the opportunities to recycle plastics are increasing.

New landfill finicky about trash

James R. Langford The Herald

YORK - The newest addition to the York County landfill won't take just any garbage.

It's designed exclusively for construction and demolition debris.

The eight-acre addition, located at the county landfill operation on S.C. 5 near York, opened a little more than a week ago and should last about five years, said landfill supervisor Rodney Smith.

It will accept non-volatile, non-toxic waste such as scrap building material, old concrete and bricks, sheetrock, shingles and lumber.

Separating construction and demolition debris from household - a rarity now that the county's main landfill is nearing capacity, explained Public Works Director Ron Lilly.

Dumping construction debris at a separate landfill means the household waste landfill, which costs more to build, will last longer.

"We should be able to divert 20 percent or 60 to 80 tons of trash daily from the regular landfill to here, where it's more suitable," Lilly said.

Additionally, a construction and demolition landfill is cheaper to operate than a regular landfill because construction-related debris does not pose an environmental hazard when it decomposes, county officials said. The debris can be safely buried in the ground and covered with dirt.

Under new regulations, handling household waste is both more costly and more complicated than disposing of construction debris.

State law requires household waste landfills built after 1991 to have plastic ground covers, drainage systems and gas monitors to prevent groundwater or air contamination. These and other mandates boost construction costs to $300,000 per acre, compared to $20,000 per acre for a construction debris landfill.

Tipping fees for a commercial debris landfill are less, too, at $20 per ton with a $5 minimum fee compared to $31.45 at the regular landfill.

Most of the debris dumped at the landfill addition comes from builders and related industries, Smith said. For example, he said, "we have a lot of roofing contractors that go in and re-roof houses and they can dump old shingles."

York County's current landfill operation has room for two additional construction debris sites, the same size as the existing one, and they've already been designed, Smith noted.

The landfill is using existing employees to staff the new operation, Smith said.

LANDFILL GAS EMISSIONS:

A STUDY OF TWO LANDFILLS IN

PRINCE GEORGE'S COUNTY, MARYLAND

Donald L. Gill, Ph.D.

EXH. 64

EXECUTIVE SUMMARY

The environmental effects and health hazards of landfill gas emissions have been largely ignored as concerns have focused instead on groundwater and surface water contamination, methane migration, odor and nuisance effects of landfills. It has become clear from recent studies that municipal landfills are a significant source of smog-forming and hazardous gaseous emissions, including many volatile organic compounds (VOCs) and a number of hazardous air pollutants (HAPs). Many of the emitted compounds are responsible for formation of ozone in the breathable atmosphere. Ozone, even at extremely low levels, presents a serious health hazard, inducing severe effects on pulmonary function, greater susceptibility to respiratory infection, major aggravation of pre-existing respiratory disorders, and alteration in the function of other tissues including blood cells, neural tissues, and endocrine organs. Landfill gas emissions also contain over 30 different HAPs that are identified as toxic under the 1990 Clean Air Act (CAA). These contain not only suspected carcinogens, but also other toxic air pollutants which can induce significant adverse effects on kidney, liver, and central nervous system function. Landfills also emit vast quantities of methane; this is not only a major "greenhouse" gas, but in the quantities produced by landfills also acts as a carrier and dispersant for the other pollutants.

A 1994 study of the 14,000 ton per day (TPD) Fresh Kills landfill in New York City estimated that in 1993 this landfill emitted 4,610 tons of smog-forming emissions; moreover, the landfill will continue to emit approximately 500 tons per year of these emissions 30 years after closure even with the placement of a final cap. The Fresh Kills emissions exceed by a wide margin virtually every regulatory threshold established under the Clean Air Act (CAA) Amendments of 1990. However, Fresh Kills is an exceptional landfill with respect to both size and location. Thus the purpose of the current report was to consider the amounts and the impact of gaseous emissions from more typically sized (500-2,000 TPD) and located landfills.

This study examines emissions from two 1,000-2,000 TPD landfills located in Metropolitan Washington, D.C. — the Sandy Hill and Brown Station Road facilities within Prince George's County, Maryland. The county falls within a "serious" nonattainment area for ozone levels as classified under the 1990 CAA. Both landfills are located in localities which have experienced significant population increases since 1985; during the same period both landfills have been substantially expanded.

The results of the study on Prince George's County landfill gas emissions can be summarized as follows:

1. The two landfills are the largest stationary sources of VOC emissions in Prince George's County. In 1994, the estimated VOC emission rates were 52.5 and 25.0 pounds per hour (230 and 109 tons per year) for Brown Station Road and Sandy Hill landfills, respectively.

2. Brown Station Road is the highest VOC emitter in Prince George's County — 50% higher even than the 2,450 megawatt Chalk Point power plant operated by PEPCO. The emission rates from either landfill clearly would trigger the regulatory threshold of 50 TPY established by the 1990 CAA for "new major sources" of air emissions. Even after planned gas collection and control devices are in place, each landfill will continue to emit VOCs exceeding that threshold until at least the year 2020.

3. For HAPs defined under the 1990 CAA, each landfill exceeds both the 10 TPY single HAP threshold and the 25 TPY combined HAP threshold in 1994. In 1994 combined HAPs emissions from Sandy Hill are estimated at 41 TPY; for Brown Station Road combined HAPs emissions are estimated at

33 TPY. Even after planned collection systems are installed, it is estimated that Sandy Hill will continue to emit tetrachloroethylene (an EPA-defined probable carcinogen) in amounts exceeding 10 TPY beyond the year 2000. Because of its continuing expansion and operation, the Brown Station Road landfill is estimated to emit 26.7 TPY of HAPs in 2017.

4. The control devices (flare and energy recovery system) at both landfills themselves generate significant quantities of air pollutants. Combined, the two landfills contribute over 80 TPY of carbon monoxide (CO) emissions and this within an area already suffering from high urban-related CO emissions. The same control devices also generate significant emissions of dioxin, a highly potent and toxic compound. Estimates for Sandy Hill and Brown Station Road indicate that dioxin emissions may be significantly increasing the quantity of ambient dioxin and dioxin exposure in the areas immediately surrounding both landfills.

5. Both landfills are expanding in areas experiencing significant increases in population. The health risks of landfill gas emissions on local populations or, in the case of Sandy Hill, on the adjoining 12,750-acre Patuxent Wildlife Refuge/Research Center, have not been adequately assessed.

Neither the State of Maryland nor the EPA currently regulates landfill gas emissions. Although the EPA proposed minimum gas controls and control standards for landfill emissions in 1991, those regulations are not expected to be final and binding until into 1995. When they do become final, compliance with gas collection and control standards will not be required for four years. This postponement of landfill gas emission control may significantly impair Maryland's ability to meet the 1996 CAA deadline for net overall reduction of smog-forming emissions by 15%. Most importantly, postponement of implementation of effective collection and control systems for landfill gases until the year 2000 or beyond may have a serious detrimental effect on expanding populations adjacent to the two facilities under study.

LANDFILL GAS EMISSIONS: A STUDY OF TWO LANDFILLS IN PRINCE GEORGE'S COUNTY, MARYLAND

I. Introduction

Recent studies reveal that municipal solid waste (MSW) landfills are a significant source of hazardous and environmentally destructive air emissions.[1] As solid waste decomposes within landfills, gases are produced comprising approximately 50% methane, 50% carbon dioxide, and approximately 1% of non-methane organic compounds (NMOC).[2] Because United States landfill gas emissions are immense — amounting to approximately 60 million tons per year (TPY) — this 1% approaches a total of 600,000 TPY.[3] This is a very significant quantity; thus, by comparison, organic chemical manufacturing and petroleum refining industries are estimated to emit approximately 680,000 and 640,000 TPY, respectively.[4]

The EPA has concluded that the NMOC's generated by landfills are primarily volatile organic compounds (VOC's) most of which contribute to the ambient ozone problem.[5] Among these NMOCs are over 30 identified Hazardous Air Pollutants (HAPs), including approximately one sixth of the entire list of toxic and other hazardous pollutants included by Congress in the 1990 Clean Air Act (CAA) amendments.[6] Several of these HAPs are proven or suspected carcinogens at low levels. Many induce other deleterious health effects including adverse effects on diverse cell types within the body including those of the kidney, liver and central nervous system.[7] Landfills also emit enormous quantities of methane, an explosive gas which not only acts as a carrier and dispersant for NMOC's, but is now considered to be a potent "greenhouse" gas contributing to global climatic change; landfills are one of the principal sources of U.S. methane emissions.

Many landfill-derived NMOC's induce formation of ozone in the breathable atmosphere which

even at very low levels has a spectrum of health manifestations ranging from mild respiratory irritation to induction of severe effects on pulmonary function, greater susceptibility to respiratory infection, aggravation of pre-existing respiratory disorders, and alteration of the function of blood cells, neural tissues, and endocrine organs.[8] Unlike most air pollutant sources which discharge at some height above the ground, landfill emissions occur at ground level where they are not readily dispersed and where humans can be exposed to the emanating gases at relatively high concentrations. At these levels they also have serious detrimental effects on crops and animals.[9] Most significantly, unlike most sources of industrial air emissions which are periodic and which can be controlled or eliminated, landfill emissions occur continuously and cannot be adjusted.

The EPA has estimated that landfills contribute over 1% of all NMOC emissions from stationary sources nationwide.[10] Landfills contribute almost half as much volatile organic compounds as all industrial sources combined, with the exclusion only of chemical manufacturing and solvent-related industries.[11] Moreover, these landfill emissions continue more than 35 years after a landfill is closed.[12]

Until recently, landfill emissions have been largely ignored. While landfills emit air pollutants which, when released from other sources are stringently regulated under the Clean Air Act, landfill emissions have not been systematically regulated by the EPA. Similarly, states, with the exception of California, have not regulated landfill emissions other than to minimize methane migration, risks of explosion, and odor problems.[13] In May 1991, the EPA proposed regulations imposing minimum

These effects have long been identified in justifying the current ozone national health standard of 0.12 ppm (parts per million). COMAR 26.11.03.05.

[9] The EPA in the proposed NSPS rulemaking for landfills stated: Ozone also warrants control due to its welfare effects, specifically, reduced plant growth, decreased crop yield, necrosis of plant tissue, and deterioration of certain synthetic materials such as rubber.
56 Fed. Reg. at 24474.

[10] 56 Fed. Reg. at 24473. Individual state estimates vary. California in 1991 collected data which indicated that landfills contributed over 2% of the VOCs emitted in that State which has serious smog problems. "Emissions Inventory 1991", California Environmental Protection Agency, Air Resources Board (January 1994).

[11] Reference 4, Table 2-10.

[12] Reference 2, Appendix D.

[13] Twenty-seven states regulate landfill emissions through solid waste regulations controlling methane migration, explosion potential and odor/nuisance. Reference 2, p. 3-38. California is one of the very few states which have adopted air quality-related regulations to control emissions from landfills. Most air pollution districts in California, however, regulate only landfill flare emissions, not uncollected emissions from the landfill. Thus, landfill operators who do not have a flare or apply for a flare permit, escape control obligations.

controls on emissions from large new and existing landfills accepting MSW.[14] These New Source Performance Standards (NSPS) impose minimum standards that large new and existing MSW landfills must meet. The NSPS regulations are the regulatory center-piece of the Administration's 1993 Climate Change Action Plan in response to the 1992 Rio de Janeiro Earth Summit.[15] However, as of the date of this study, final landfill gas emission rules are not expected until Spring 1995. In November 1993, Maryland submitted its State Implementation Plan to meet the 15% rate-of-progress reductions in smog-forming emissions mandated by the CAA. Maryland committed to impose landfill controls based on the federal rules,[16] however, to date, Maryland has not proposed specific regulations.

In October 1994, the EPA issued guidance clarifying that uncontrolled landfill gas emissions must be considered in determining whether a new proposed landfill's potential emissions were subject to the CAA new source review requirements.[17] The rationale underlying that guidance also should lead to imposition of "Reasonably Available Control Technology" (RACT) emission controls[18] for each existing landfill with potential emissions deemed as "major." In areas of "serious" non-attainment of air pollution standards, which includes Prince George's County, Maryland, "major" is defined as potential VOCs of 50 TPY, whether or not a collection system has been installed.

Recent studies have examined air emissions from large existing landfills such as the Fresh Kills Landfill, which serves as New York City's only municipal landfilling facility.[19] Fresh Kills is a 14,000 TPD landfill, first opened in 1948, with 90,000,000 tons of solid waste now in place. In addition to creating the traditionally considered gas migration and odor problems, Fresh Kills is a major source of VOC's, nitrogen oxides (NO_x), and carbon monoxide CO, exceeding the regulatory thresholds of the 1990 CAA by very wide margins.[20] Fresh Kills is estimated to have emitted 4,610 tons of VOCs in the year 1993. It will continue to emit hundreds of tons of VOCs per year even in 2046, 30 years after anticipated closure.

[18] RACT is a site-specific determination; the EPA defines it as: "the lowest emission limitation that a particular source is capable of meeting by the application of control technology that is reasonably available considering technological and economic feasibility". 44 Fed. Reg. 53761 (September 17, 1979).

[19] Minott, David H., "Landfill Environmental Emissions - Regulatory Progress and Gaps", 1994 Annual Conference of the Solid Waste Association of North America (SWANA), New York State Chapter, Rochester, New York, June 13-17, 1994, at 19.

[20] Reference 19, p. 19.

These emissions are alarming since they exceed by a wide margin virtually every regulatory threshold established under the Clean Air Act Amendments of 1990.[21] They raise the question of what amounts of atmospheric pollutants are currently being emitted from smaller, more typical-capacity landfills, that is in the 500-2000 TPD range. About 1650 such landfills and 5,580 landfills of smaller size, are currently operating in the US.[22]

The current study examines emissions from two fairly typically sized and operated landfills (1,000-2,000 TPD) in Metropolitan Washington, D.C. These are the Sandy Hill Landfill and Brown Station Road Landfill both located in Prince George's County, Maryland. This study documents the emissions and potential health effects that can be expected from landfills of this size. It is the first comprehensive study of these two landfills.[23]

II. Landfill Gas Control Technology

Emissions and offsite gas migration from landfills can be reduced by landfill gas control systems comprising networks of porous pipes installed to collect gases produced by decomposing solid waste. Negative pressure within the system produced using blowers and/or compressors is used to collect and direct gases to vents or control devices. Impervious landfill caps reduce uncollected emissions of gas to the air.

The three main types of gas control devices are: (1) combustion of landfill emission gases in turbines or reciprocating engines to utilize the energy potential of methane and other combustible gases present; (2) gas purification or "cleaning" to remove certain contaminants and impurities before sale to local gas utilities, and (3) burning of high methane-containing landfill gases in flare devices prior to release into the atmosphere. Although the most convenient, from environmental and health perspectives flares have significant problems. For example, they may only partially control VOC and other toxic constituents, and combustion may itself cause formation of other toxic agents (see below).

One of the most significant problems of gas collection systems is their inefficiency. The efficiency of landfill gas control depends on the fraction of gas collected by the gas collection system and, for that portion which is collected, on the destruction efficiency of the flare or engine. While the EPA has stated that the efficiency of landfill gas collection systems has not been directly measured,[24]

---

[21] Reference 19, p. 15.

[22] Reference 2, p.3-2.

[23] For purposes of the 1990 ozone emission inventory, the State has estimated VOC emissions from the two landfills in 1990 at about 1.08 tons per day. MDE, The 1990 Base Year Inventory for Precursors of Ozone, Final Draft (Sept. 30, 1993), Vol.1A, p. 3-92. This figure is higher than the estimates of this study because it did not take into account collection and control systems which have been installed at the two landfills.

[24] Reference 2, p. 4-9. Estimates for landfill gas typically reflect general formulas based on quantities of solid waste deposited plus an assumed "decomposition rate."

it has indicated that a 50-60% efficiency is achievable for a well-designed system,[25] and that a collection efficiency of 60-85% may be possible as an upper limit of effectiveness in collecting total landfill gases emitted.[26] With such efficiencies, about one-quarter to one-half of the gas generated by a landfill is not collected and is emitted to the ambient air. For the fraction of gas collected, the EPA believes that control devices can achieve 98% destruction of NMOCs.[27] However, of the 27 states identified by the EPA as regulating emissions from MSW landfills for safety purposes, only California requires periodic testing of the efficiency of controls.[28] Moreover, when control devices are operating correctly, approximately 2% or more of collected gases (including significant proportions of the more hazardous NMOCs) pass through the control device without being destroyed.[29]

In addition, combustion type "control" devices such as flares, engines and turbines, themselves form and emit air pollutants. These include nitrogen oxides (NOx), carbon monoxide, sulfur dioxide, hydrogen chloride, carbon dioxide, particulate matter and VOCs. These combustion devices also generate and emit significant quantities of highly toxic dioxin.[30] Indeed, as the destruction efficiency for VOCs increases, the emission rates of NOx and dioxin also increase.

III. The Landfills

A. Background

The Sandy Hill and Brown Station Road Landfills in Prince George's County, Maryland, are both located within residential regions with sizable local populations existing in areas into which prevailing winds permit migration of gases (Figs. A and B). Since 1985 the population surrounding each landfill has increased significantly. However, the Prince George's County Ten-Year Solid Waste Management Plan relies on both landfills as the only disposal sites for the County; therefore, without other waste disposal options, emissions from these landfills will continue to increase.[31] To

accommodate the disposal needs posed by its expanding population, the County is conducting substantial expansions of both landfills, both vertically and horizontally, so each may continue to accept waste well into the next century.[32]

B. Sandy Hill

The Sandy Hill landfill is a municipal solid waste disposal facility of about 220 acres serving the northern sector of Prince George's County.[33] It is located on the Laurel-Bowie Road about two miles northwest of the town of Bowie directly adjacent to the Federal Patuxent Wildlife Research Center and a growing residential community (Fig. A).

From 1978 through 1993, over 5.9 million tons of refuse (averaging more than 1,000 TPD) were deposited in the landfill.[34] This solid waste comprises approximately 30% residential waste, 55% commercial waste, and 15% demolition debris.[35] The landfill site was originally acquired in 1977 by the Maryland National Capital Park and Planning Commission and leased to the County which is responsible for the landfill's operation and maintenance; the County contracted this responsibility to the solid waste disposal operator, Waste Management, Inc. of Prince George's County.[36] At the time of opening the landfill in 1978, the County planned to close the landfill in 1992. However, in the late 1980's the County reversed this plan and opted for expansion of the landfill both vertically and horizontally. If the horizontal expansion is approved by the Maryland Department of the Environment (MDE), the landfill will be accepting MSW at least until the year 2004.[37] Upon closure of the landfill, the County plans to use it as a public recreational facility containing soccer fields, an amphitheater and

[32] Reference 31, Ch. 3, Section XI.

[33] Reference 31, p. 3-14. The landfill is officially known as the Sandy Hill Creative Disposal Project.

[34] Sandy Hill 1992-1993 Annual Report, p.13.

[35] "Estimates of Gas Recoverability, Sandy Hill Landfill, Prince George's County, Maryland", prepared by EMCON for Waste Management of Prince George's County, Inc. (Dec. 4, 1985).

[36] Reference 31, p. 3-14 - 3-15.

[37] Based on the County's 10-Year Solid Waste Management Plan, the Sandy Hill landfill will likely be used to dispose MSW well after 2004. First, the County lists as disposal sites for its 10-year planning period only Brown Station Road and Sandy Hill. No other disposal alternative is identified, although the County does plan to increase recycling and reduction sources. Permitting of an additional facility is a process requiring several years to complete, even after that facility is identified and approved by the County Council. Second, the County's record of operation, as exhibited at both Sandy Hill and Brown Station Road landfills, has been first to horizontally expand an area, then to vertically expand it. Thus, it is very conceivable after the horizontal expansion is permitted, the County will apply for a vertical expansion. For these reasons, the expected closure dates in this study are conservative.

a running track, as well as access roads and parking areas.[38]

Areas of residential housing directly adjoin both the existing landfill and the planned area of expansion (Fig. A). A predominantly African-American community has resided along the nearby Duckettsville Road area since the turn of the century. Moreover, the residential population adjacent to the landfill has increased significantly. The 1990 Census reported 3,135 residents within a 0.5-mile radius of the landfill, increasing to 122,344 residents within a 5-mile radius of the site.[39] Between 1985 and 1990, the number of families near the landfill grew significantly: approximately one quarter of the housing units within a 0.5 to 1.0-mile of the Sandy Hill facility were constructed after 1985.[40]

The Sandy Hill landfill additionally borders the federal Patuxent Wildlife Research Center, an extensive forest, meadow and wetland animal and plant habitat of 12,750 acres managed by the U.S. Fish and Wildlife Service.[41] Research at the Center focuses on evaluation of environmental contaminants, assessment of populations and habitats of migratory birds, and restoration of endangered species. It was the site at which Rachel Carson obtained much of the material for the wildlife portions for The Silent Spring, which warned of the dangers of DDT and other pesticides.[42] In October 1994, the National Wildlife Visitor Center opened; built with $15 million of federal funds, the Visitor Center is the Department of the Interior's largest science and environmental educational facility. Designed to accommodate one million visitors a year, the Center offers hiking trails, wildlife management demonstration areas, outdoor education sites for school classes, and a tram tour of surrounding habitats.[43]

In 1990, the County applied to the MDE for a 134-acre horizontal expansion to the area west of Duckettsville Road and southwest of the Patuxent Wildlife Research Center. Fig. A shows that the proposed expansion areas not only increase the landfill's border with the Wildlife Center, but also adjoin additional population areas west of the existing landfill. According to the revised application, the annual disposal rate would be 495,000 to 536,000 tons per year of waste in the 72 acres which comprise the requested horizontal expansion fill-area.

[43] U.S. Department of Interior, National Biological Survey, October 1994.

By Spring 1992 the proposed horizontal expansion plan had not been approved by the MDE nor was it close to receiving approval. Instead, the proposal for expansion was still in its Phase II, an information-gathering phase in which various environmental studies are performed.[44] In April 1992 the County applied for a vertical expansion of the original site plan since the existing landfill was exhausting its capacity. In October 1992 the PGC Director of Environmental Resources asked the MDE to authorize the vertical expansion by issuing a Consent Order which would allow the County to begin using the vertical expansion in January 1993.

In January 1993 the MDE issued a final Consent Order authorizing the vertical expansion until either the horizontal expansion is permitted or the vertical expansion is filled to capacity.[45] As of the date of this study, the vertical expansion continues to be filled at approximately 1,150 TPD.[46] It is expected to be filled to capacity in 1996. The horizontal expansion application has still not advanced beyond its Phase II status. The County anticipates the horizontal expansion to be operational beginning in 1997 and to reach capacity by 2004.[47]

The original Sandy Hill Solid Waste permit required installation of a gas collection system and flare to control methane gas levels for explosion-prevention purposes but only after the originally permitted area was filled to capacity and capped. In the late 1980's, after explosive levels of methane were detected near residences on Duckettsville Road, the MDE amended this permit and ordered immediate installation of gas collection wells exhausted via pipes leading to an enclosed flare. In 1992, the MDE found high levels of VOC's in groundwater monitoring wells in the eastern portion of the landfill near the Duckettsville Road residences. In the Consent Order authorizing the vertical expansion, the MDE required the landfill operator to investigate the source of these VOCs and evaluate whether remediation was necessary. The resulting Groundwater Investigation Report, released in 1994, concluded that landfill gas migration was the source of the elevated levels of VOCs in the groundwater.[48] It recommended accelerating installation of gas collection wells. The report also

---

[44] In Maryland, solid waste permitting has 5 phases: Phase I - preliminary phase when the State determines if it is feasible to build a landfill on a proposed site; Phase II - information gathering when hydrogeological, geographical and other studies are undertaken; Phase III - design; Phase IV - internal MDE review for permitting requirements; Phase V - public comment, public hearing, notice of decision to issue a permit, and "contested case" hearings if requested. COMAR 26.04.07.

[46] 1993 Annual Report for Sandy Hill Landfill filed with MDE.

[47] This assumes horizontal expansion is permitted and commences operation in 1997. The County estimates a 7-year operational life for the horizontal expansion. Phase II Permit Application for the Solid Waste Disposal Project Expansion (August 1990; revised January 1991). The history of the two landfills in Prince George's County described in this study as well as those of other Maryland counties, indicates that the facilities will continue operation well beyond projected closure dates due to expansions.

[48] RUST Environmental & Infrastructure, Ground Water Investigation Report, Vol. I, 1994.

suggested excavation of trenches where VOC concentrations were the highest.

Currently, the landfill operator has installed gas collection wells and controls in only a limited portion of the geographical footprint of the fill area. These installations comprise 14 perimeter gas wells used to reduce gas migration toward the Ducketts ville Road residences, and 40 wells located directly into the compacted solid waste in place.[49] The operator plans to install another 42 remaining gas collection wells only when the vertical expansion reaches final capacity, now predicted for 1996.[50] In addition, the operator has installed a final cap on only 39 of the 72 originally filled acres on which the vertical expansion rests, stating it cannot go further until the MDE reaches a regulatory determination on the composition of the final cap. The lack of installation of an effective gas collection and control system, including a final cap on areas already filled to capacity, results obviously in increased VOC emissions from the landfill (see Table 1, discussed below).

Similarly, the Sandy Hill landfill permit plans for the horizontal expansion do not include any provision for gas collection and control on the 72-acre footprint until after that horizontal expansion area is also filled to capacity, now projected for 2004. This will result in no landfill gas controls being in place in the horizontal expansion area for at least seven years.

C. Brown Station Road Landfill

The Brown Station Road landfill is located approximately two miles northwest of Upper Marlboro (see Fig. B-1). It is operated directly by Prince George's County and is the primary municipal solid waste landfill for the central and southern portions of the County.[51] The landfill began accepting waste in 1968. Between 1968 and 1993, it received 7,818,000 tons of refuse, an average of 1,108 TPD. In 1990, the MDE authorized a horizontal expansion of the facility. By 1993 the first section of the landfill (Area A) had been filled, and refuse was being deposited exclusively in the horizontal expansion area, designated Area B. (See Fig. B-2). At current fill rates, the landfill is anticipated to close in 2015. As with the Sandy Hill facility, the County currently plans to use the area as a public recreation facility after landfilling ceases and closure is complete.[52]

The 1990 Census reported that 6,409 individuals were living within 0.5 miles of the landfill, 10,556 within a mile, and 103,224 within 5 miles of the facility.[53] Like Sandy Hill, the Brown Station Road area has experienced significant residential growth since 1985. Between 1985 and 1990, the number of housing units within a half-mile of the landfill increased by almost 25%. Within a mile

[49] Id., p. 2-3.

[50] Id.

[51] Reference 31, p. 3-14.

[52] Id.

[53] Maryland Office of Planning, "Brown Station Landfill 1/2, 1, and 5 Mile Radius Summary, 1990 Census Profile - Population and Housing Characteristics," Summary Tape File 1B, 3A, prepared October 4, 1994. These data are subject to sampling variations and other limitations.

there was a 41% increase in housing units.[54] These numbers do not reflect residential growth that has occurred since 1990.

Area A (Fig. B-2) predominantly comprises two vertical fill areas occupying 150 acres. Between 1968 and 1993, this area received more than 7.4 million tons of solid waste. Due to the age of this section, no clay or synthetic liner was installed prior to the start of operations, and solid waste has been deposited directly on preexisting soil since the landfill's inception. A total of 29 gas collection wells have been installed over a limited extent of the initial site, that is, approximately 25 acres of Area A1 (Fig. B-2); these wells collect only approximately 10% of the total gas generated from the initial fill area. The collected gas is pumped to an on-site compressor building where it is dried and cleaned. The residual gas (predominantly methane and CO_2) is then piped to the Prince George's County Detention Center approximately 1 mile away, where it is used to power generators and boilers which supply electricity, heat and hot water to the Detention Center. The 10-Year Plan states that the County anticipates expanding this service to a nearby County Office Building, but no funds have been allocated for that purpose.[55]

Currently there are no other gas collection wells at the landfill. An upper synthetic liner is planned to cap all of Area A before 1997. At that time, installation of 150 gas collection wells leading to the compressor building is planned in Area A. Gas not consumed by the correctional facility will be flared to the open air.

The horizontal expansion (Area B) has an actual fill area of about 120 acres and began accepting waste in 1993.[56] When complete, Area B will consist of eleven cells forming an integrated disposal area. The County expects that approximately one cell will be filled per year. thus, Brown Station Road landfill is currently planned to remain open until at least 2015. Each cell will have both a clay and a synthetic bottom liner. Once Area B is closed, a synthetic cap will be installed covering the entire sector. In addition, it is expected that a gas collection system will be installed at closure and that gas will be piped to the compressor building and flared if it is not needed by the Detention Center generators. There are no plans to install any gas collection system prior to closure and capping of Area B unless regulatory requirements change.

IV. Landfill Gas Emission Estimates

A. Introduction

Currently only very limited landfill gas collection and control systems have been installed in either landfill; no more than 25% and 10% of gas emissions are currently collected at the Sandy Hill

[54] Id.

[55] Reference 31, p. 4-17. No capital funds for expansion of power generation to any facility have been allocated by the County to date. Therefore, only about 10% of the gas produced by Brown Station Road landfill will be used in energy recovery. Tables 1-2 are based on the latter assumption.

[56] Id., p.3-14.

and Brown Station landfills, respectively. As of the time of the present study, permits issued by the MDE do not require installation of any additional collection systems or gas controls, other than those already in place, until operational areas are filled to capacity and capped.[57] Until the time of closure, both facilities will continue to emit large quantities of landfill gases into increasingly populated areas; moreover, these areas already exist within a "serious ozone non-attainment region". In the case of Sandy Hill, emissions will also affect a sensitive, 12,700-acre federal wildlife refuge/research center.

The landfill gas emission estimates for both landfills indicate that each of the two sites are among the highest-emitting stationary VOC sources in the County. Because Prince George's County is within a "serious" nonattainment area for ozone, the 1990 CAA requires Maryland to implement additional control measures designed to reduce County levels of smog-forming emissions by substantial amounts while offsetting the considerable growth in VOC emissions since 1990. Currently, Maryland, like most other states, does not regulate landfill gas emissions except for traditional controls to minimize the potential for methane explosion and flare emissions. Maryland has not applied CAA new source review principles to emissions at either landfill, although the emission rates far exceed applicable regulatory thresholds. Neither the federal, State or County governments have addressed the effects of these emissions on the growing residential population, on the critical federal wildlife refuge adjoining Sandy Hill, or on the State's ability to meet the smog-reduction goals of the CAA.[58]

Table 1 estimates the air emissions from the Sandy Hill and Brown Station Road landfills, based on widely-accepted EPA emission factors and procedures for calculating landfill emissions. The data reveal that emissions of VOCs and HAPS exceed by a wide margin the regulatory thresholds of the Clean Air Act Amendments of 1990. The emissions for the two Prince George's County landfills include (1) "uncollected VOC emissions," that is, the quantity of gas generated but not captured by current collection systems; (2) "residual VOC emissions," that is, the amount not destroyed by flare; and (3) non-VOC emissions from the control device which are byproducts of landfill gas combustion.[59]

"Uncollected" and "residual" emissions were estimated by applying the U.S. EPA Landfill Air Emissions Estimation Model.[60] The emissions of HAPs were estimated using a combination of site-specific data and EPA emission factors.[61] "Non-VOC emissions" from the control device were estimated using data from the NSPS Background Document[62] except for dioxin which was derived from actual test data reported in the published literature.[63]

B. VOC Emissions

For 1994, the estimated VOC emission rates for Sandy Hill and Brown Station Road landfills are:

Landfill	Pounds Per Hour	Tons Per Year
Brown Station Road	52.5	230
Sandy Hill	25.0	109

These numbers indicate that Brown Station Road landfill is the highest stationary VOC emission source in Prince George's County — 50% higher even than the 2,450-megawatt power plant at Chalk Point operated by Potomac Electric Power Co. The VOC emissions from Brown Station Road exceed by 4-fold the 50-TPY threshold established under the CAA. The VOC emissions from Sandy Hill are more than double that threshold. By comparison, the following are the 5 highest point sources of VOC emissions in Prince George's County, based on MDE data:[64]

Potomac Electric Power - Chalk Point Power Plant	35.50 lbs/hr	155.5 TPY
Safeway Co. Bread Bakery	20.25 lbs/hr	88.7 TPY
Hollady Tyler Printing	20.25 lbs/hr	88.7 TPY
Andrews Air Force Base	19.91 lbs/hr	87.2 TPY
Duron Paint plant	18.25 lbs/hr	79.9 TPY

[57] See, for example, Phase 1A Landfill Gas Extraction Wells and Condensate Traps" Bidders documents for Gas Collection at the closed portion of the Brown Station Landfill, Mary 26, 1994. See also, "Application for a Landfill Gas Management and Enclosed Ground Flare System," Sandy Hill Creative Disposal Project Bowie Md., (Sept. 1990), Prepared for Waste Management of Prince George's County, Inc., Maryland National Capital Parks and Planning Commission.

[58] For example, while the County 10-Year Plan addresses potential ground and surface water contamination, wetlands, soils, and sensitive environmental areas, it does not discuss the EPA landfill gas regulations proposed in 1991 or otherwise address such ambient emission issues. See Reference 31, Ch. 4.

[59] As noted above, the latter includes dioxin.

[60] US EPA, "Landfill Air Emissions Estimation Model Users Manual," Radian Corp., US EPA-600/8-90-85a (April 1991).

[61] These estimates were based upon actual inlet gas data from the Sandy Hill landfill (original and vertical expansion), as included in Appendix F to the Permit Application to Operate an enclosed landfill gas flare. The application was originally received by the State October 9,1990. For Brown Station and the Sandy Hill Horizontal Expansion, VOC emission factors were derived from "Emission Factor Documentation for AP-42 Section 2.1, Refuse Combustion," USEPAOAQPS (September 1992). These data then served as the inputs to the EPA Landfill Gas Estimation model.

[62] Reference 2, Table 4-4.

[63] Reference 30.

[64] Maryland Department of Environment, 1990 Base Year Inventory For Precursors of Ozone (September 30, 1993).

Table 1 shows that both landfills will continue to emit VOCs exceeding the 50 TPY threshold until at least 2020, even after installation of the controls now planned by the County. This table assumes that Sandy Hill will cease accepting solid waste in 2004 and Brown Station in 2015, as planned.[65] Gaseous emissions will continue far beyond these dates because of the continuous nature of waste degradation. These estimates are likely to be significantly below actual levels emanating from each landfill since further expansions of both facilities are likely to be sought and permitted.

The Sandy Hill and Brown Station Road emissions rates clearly would trigger the regulatory thresholds established by the 1990 CAA for "new major sources". The CAA requires that in areas of "serious" nonattainment which includes Prince George's County, "new source review" is required before any construction of a facility may commence if potential emissions of VOC and/or NOx would exceed 50 TPY at any time. Under the New Source Review, both landfills would be required to:

1. Install Lowest Achievable Emission Rate (LAER) controls;
2. Secure emissions "offsets" for any remaining emissions;
3. Conduct health risk and siting assessments demonstrating that their benefits "significantly outweigh" the environmental and social costs;
4. Show all other in-state facilities controlled by the owner/operator comply with applicable air quality mandates.

Neither landfill is new; each is an "existing" facility. However, under the CAA, if a "modification" of an existing source exceeds the pertinent threshold, New Source Review would independently also apply to that modification. A landfill expansion would be considered just such a modification. Indeed, each of the planned landfill expansions by themselves would exceed the 50 TPY threshold and therefore be sufficient to trigger new source review under the CAA (Table 1).[66]

Even if neither landfill is subject to New Source Review, the rationale for EPA's October, 1994 Guidance should require prompt imposition (on "major" existing landfills) of "reasonably available control technologies" (RACT), which historically has meant at least 90% collection and 90% removal. For similar reasons, this guidance should require the landfills to apply promptly for comprehensive CAA operating permits with public hearings on the acceptability of proposed emission limits and other requirements. In the 1990 CAA Amendments, Congress directed the EPA to require these permits because it believed they would promote more consistent emission controls as well as better compliance and enforcement.

[65] The magnitude of estimated VOC emissions for Sandy Hill is confirmed by data in the Ground Water Investigation Report ordered by the MDE which have been conclusively interpreted to indicate that the high levels of VOCs in groundwater around the fill area actually result from migrating landfill gases dissolving in groundwater. See Reference 48.

[66] These numbers are conservative. Under the CAA, a new "modification" does not have to possess potential emissions large enough to make it a "new source" by itself. It need only have potential emissions sufficient to represent a "significant" increase over previous emissions at the facility. For VOCs and NO_x, this smaller "significance" threshold is 40 TPY. For "listed" HAPs such as vinyl chloride, that rate is 0.1 TPY or less. For HAPs such as dioxin or polycyclic aromatic hydrocarbons (PAHs), any increase is "significant." See, 40 CFR § 52.21(b)(23)(1993).

In summary, the Sandy Hill and Brown Station Road landfills are the largest stationary sources of VOC emissions in Prince George's County. They will continue to emit VOCs exceeding the CAA thresholds for the next 25 years, even after planned gas collection and control devices are in place. These landfills are being expanded in increasingly populated areas without health risk or siting analysis demonstrating that the benefits "significantly outweigh" the environmental and social costs. Indeed, County and State landfill planning has proceeded with little regard to landfill gas emissions.

C. Hazardous Air Pollutant (HAP) Emissions

The CAA listed 189 compounds as Hazardous Air Pollutants (HAPs) and classified as a "major source" for toxic regulatory purposes, any facility with potential emissions of 10 tons per year for any single HAP or 25 tons per year for two or more listed HAPs.[67] If a source exceeds these thresholds, Maximum Control Technology (MACT) must initially be installed.[68] The CAA defines MACT to include "a prohibition on (HAP) emissions, where achievable", as well as any combination of control devices, process changes, work practice, and total enclosure of emitting activities. While the EPA is not scheduled to issue national MACT standards for MSW landfills until the year 2,000,[69] it has already included MSW landfills on that MACT schedule as a significant emission source of HAPs. Moreover, Congress also directed that MACT individually be applied to any new HAP source or any significant modification of an existing HAP source, after approximately mid-1995.[70] MACT for new major HAP sources cannot be less stringent than control levels achieved at the best controlled similar facility anywhere in the country. MACT for existing major HAP sources cannot be less stringent than the average control by the best controlled 12% of such facilities.

In its 1991 proposed NSPS rulemaking, the EPA expressed substantial concern about cancer risks from landfill gas emissions. In reviewing landfill emissions data, that Agency has identified over 30 known and suspected carcinogens including tetrachloroethylene, benzene, vinyl chloride, and trichloroethylene, in landfill gas emissions.

Table 2 estimates emissions rates of HAPs for both landfills. Specific carcinogens are noted. In 1994, combined HAP emissions from Sandy Hill were approximately 41 tons per year. In 2000, HAP emissions are about 37 tons per year, even with planned gas collection and controls in place. At Sandy Hill, the single HAP tetrachloroethylene, identified by EPA as a probable carcinogen, exceeds 16 tons per year through the year 2000. At Brown Station Road, combined HAPs exceed 32 TPY in 1994 alone, with toluene exceeding the 10 TPY single HAP threshold. Because of its continuing expansion and operation, the Brown Station Road landfill is estimated to emit 26.7 TPY of HAPs in 2017.

Within the spectrum of emissions emanating from the landfills are a considerable number of compounds which have been identified as probable human carcinogens. For example, the estimated

[67] CAA 1990, § 112(a)(1).

[68] CAA 1990, § 112(d).

[69] 58 Fed. Reg. 63941 (Dec. 3, 1993).

[70] CAA § 112(d), 112(g).

emissions for Sandy Hill in 1994 include compounds such as methylene chloride (7.6 TPY), tetrachloroethylene (18.7 TPY), vinyl chloride (0.4 TPY), benzene (0.9 TPY), trichloroethylene (2.1 TPY), and 1,1-dichloroethane (1.4 TPY). Each of these compounds has been recognized as increasing the incidence of cancer in laboratory animals when administered at low concentrations; for example, it is considered that ingestion of water containing tetrachloroethylene or methylene chloride at or above 5 parts per billion (ppb) would significantly increase the incidence of cancer. This extremely low level therefore defines the upper limit permitted within water for consumption. Each of these compounds can be ingested either through air or drinking water. It is likely that the levels that are being emitted into the ambient air from each of the landfills would result in significant ingestion or inhalation by humans or animals within the vicinity of the facilities. The high population density within the areas adjoining the two facilities would provide a greatly increased risk of long-term exposure of humans to these HAPs.

D. Carbon Monoxide/Dioxin Emissions

In the process of "controlling" collected landfill gases, devices such as flares, engines and turbines themselves generate air pollutant emissions, called "secondary emissions."[71] Pollutants generated by these control devices include nitrogen oxides, carbon monoxide, sulfur dioxide, hydrogen chloride, carbon dioxide, and particulate matter. There is also specific evidence that these combustion devices produce and emit dioxin,[72] which is considered to be one of the most potent hazardous emissions.

Table 3 shows the CO emissions generated by the installed flare at Sandy Hill and the generator and flares at Brown Station Road. The two landfills contribute over 80 tons per year of CO emissions to Prince George's County, which is listed as a non-attainment area for this pollutant.[73] The same devices are known to generate dioxin emissions.[74] The EPA has been engaged in a reassessment of the health effects of dioxin and related compounds since 1991. In the first half of 1994 the EPA released "review drafts" which preliminarily concluded that exposure to dioxin results in a broad range of biochemical and biological effects in animals and, probably, in humans.[75] These effects are likely to range from possibly adverse adaptive changes at or near background levels to increasingly severe adverse effects as exposures increase above background. While it is not possible to identify the levels

[72] Reference 30.

[73] COMAR 26.11.06.04.

[74] Reference 30.

[75] "Estimating Exposure to Dioxin-Like Compounds--Review Draft" (Volumes I-III) EPA/600/6-88/005Ca (June 1994). The EPA stated in these draft documents that the reports should not be cited or quoted until they are fully reviewed by the public and EPA's Science Advisory Board. However, since they represent the most recent and comprehensive analysis of dioxins currently available and much of the factual data has been peer reviewed, some of the conclusions in the documents are noted here. The reader is cautioned that the conclusions in the cited documents have not been finalized.

at which humans undergo detectable deleterious effects, the EPA suggests that the margin between background levels and levels at which effects are detectable is much smaller than previously estimated.[76] A recent risk study estimated that with multiple exposure (i.e., through inhalation, food consumption, and air deposition) increased cancer risk from a 1,500 ton per day landfill with a flare to would 0.25 chances per million.[77]

Table 4 provides dioxin estimates for both Prince George's County landfills based on currently planned gas controls. While the numbers appear small, comparison to EPA's assumed background levels indicates that dioxin emissions from the Sandy Hill and Brown Station Road landfills may be significantly increasing the amount of ambient dioxin and dioxin exposure in the areas surrounding the landfills. In its draft Health Assessment for Dioxin and Related Compounds, the EPA assumed a background exposure of 120 pg TEQ/day.[78] For 1994, the Brown Station Road estimate of 6.0×10^6 pg TEQ/day and the Sandy Hill estimate of 2.6×10^7 pg TEQ/day indicate increased ambient exposures to dioxin that are 50 to 216 thousand times the EPA assumed background exposure for individuals living in the area adjoining the landfills. Due to the proximity of residential housing as well as the environmentally-sensitive Patuxent Wildlife Refuge and Visitor's Center nearby, these data warrant closer examination of potential dioxin emissions.

V. CONCLUSIONS

The Brown Station Road and Sandy Hill landfills are both located in an area classified as a "serious" ozone non-attainment area by the CAA. This area is increasingly being populated; for example, over 10,000 people live within one mile of the Brown Station Road facility. Sandy Hill also has experienced substantial increases in its adjacent population. Moreover, it borders an environmentally-sensitive federal wildlife refuge/research center with an expected 1 million visitors a year.

Both landfills are the largest stationary emitters of VOCs in the County, exceeding the CAA threshold of 50 TPY by a wide margin. Both landfills, even after planned closure and the installation of planned gas collection and control devices, will continue to emit VOCs exceeding these thresholds

[76] "Health Assessment for 2,3,7,8-Tetrachlorodibenzo-p-Dioxin (TCDD-and Related Compounds-Review Draft"), Vol. III, EPA/600/BP/-92/001c, (August 1994), at Section 9-11. The EPA stated in these draft documents that the reports should not be cited or quoted until they are fully reviewed by the public and the EPA's Science Advisory Board. However, since they represent the most recent analysis of dioxins currently available and much of the factual data has been peer reviewed, some of the conclusions are noted here. The reader is cautioned that the cited documents have not been finalized.

[77] Jones, Kay H., "Comparing Air Emissions from Landfills and WTE Plants," Solid Waste Technologies (March/April 1994).

[78] Reference 76, p. 9-15, footnote 2. The EPA's assumed background exposure rate to dioxin and related compounds (120 pg TEQ/day) appears reliable since this number is comparable to estimates for several other countries which range from 79 (Germany) to 118-290 (Canada) pg TEQ/day. Id..

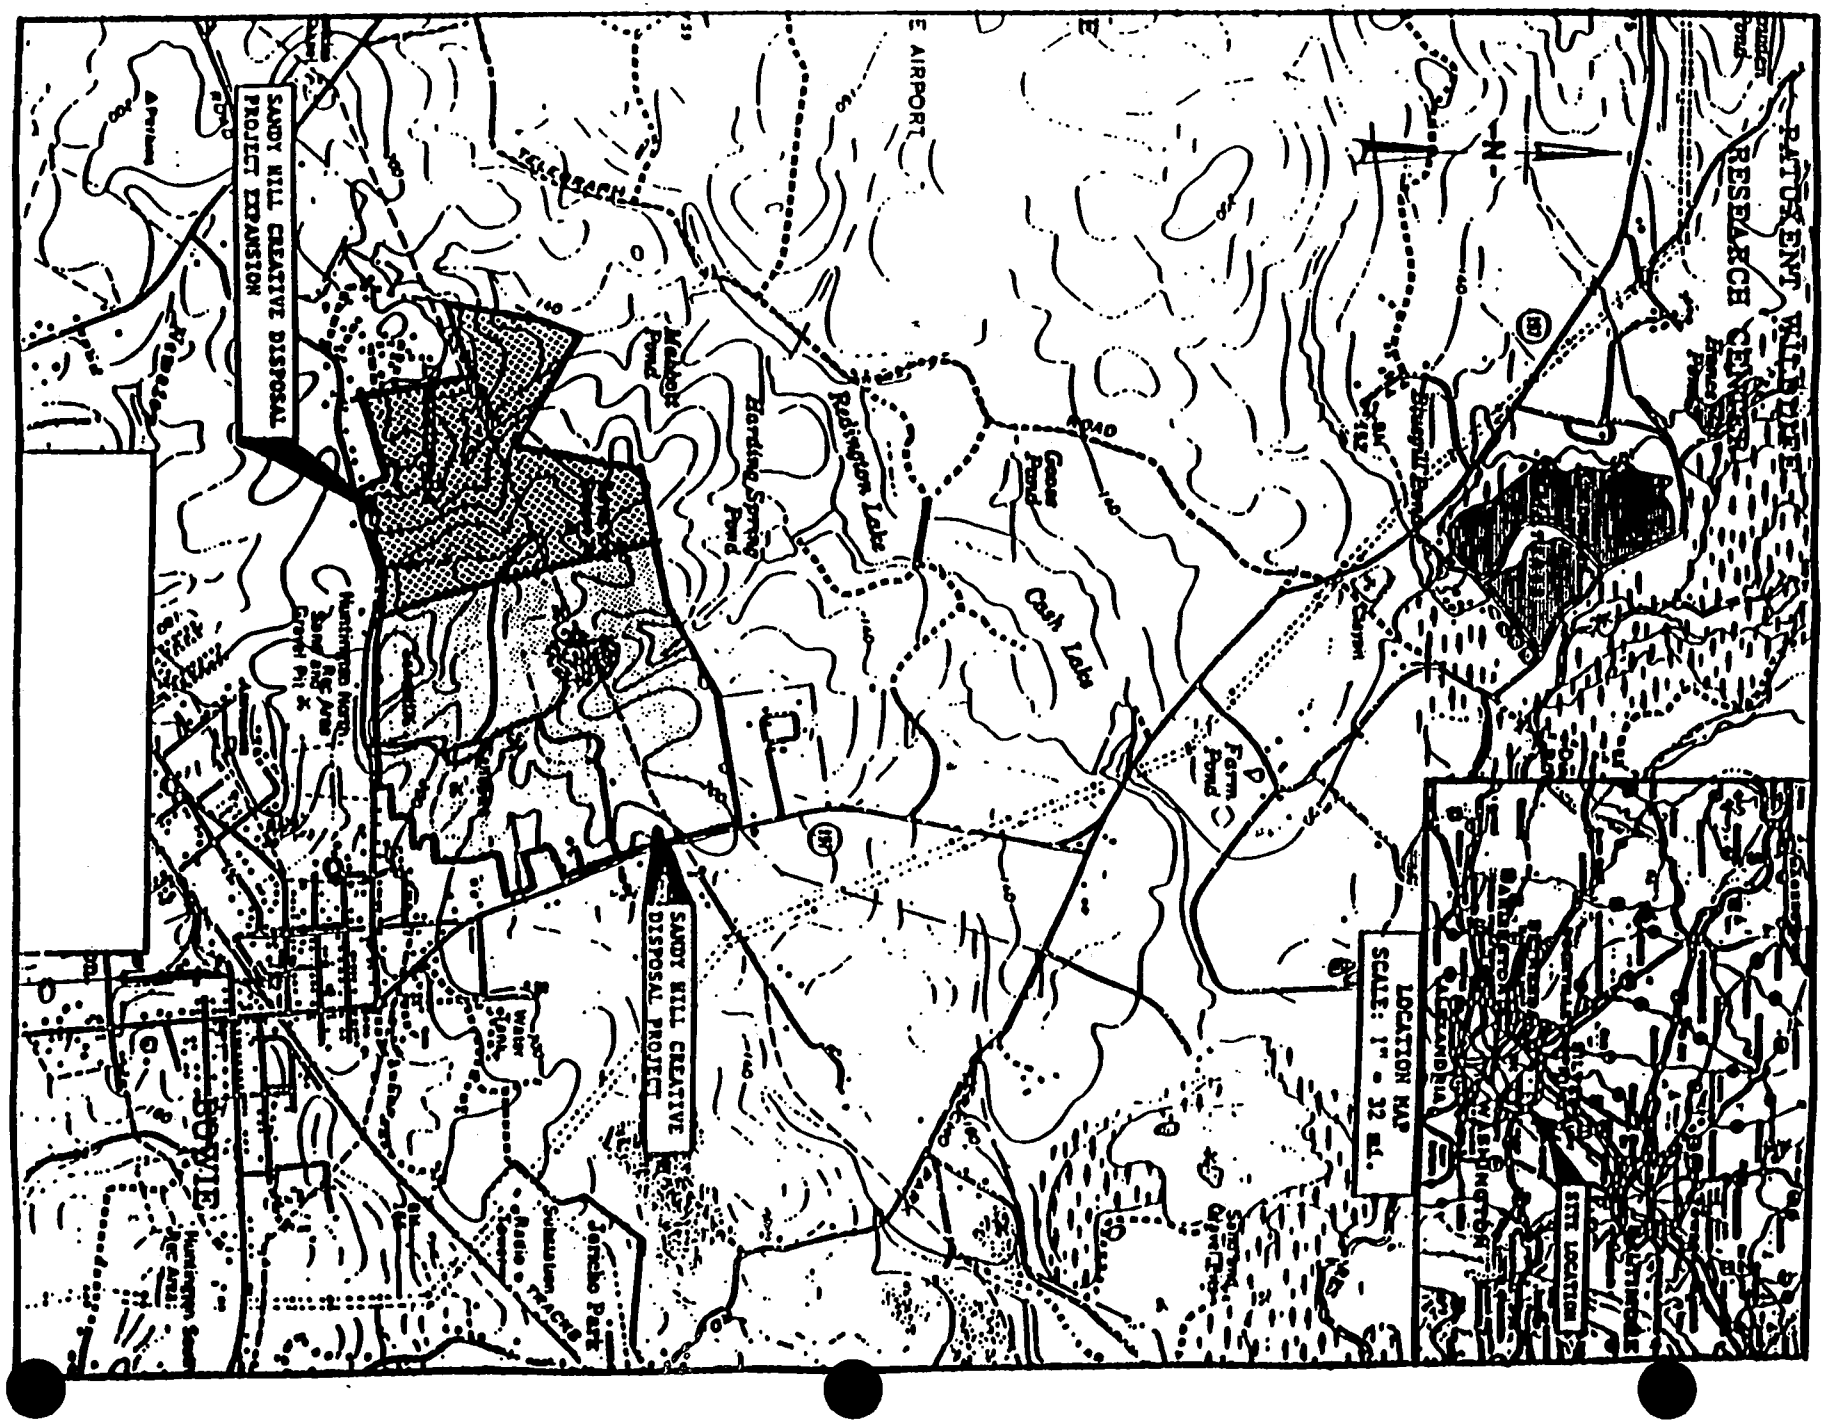
well after 2020.

The landfills also emit hazardous air pollutants into the air in amounts exceeding both the CAA-defined limits of 10 TPY for single hazardous agents and the 25 TPY for combined hazardous agents. Even after planned collection systems are installed, Sandy Hill will emit tetrachloroethylene, an EPA-defined probable carcinogen, in amounts exceeding 10 TPY in the year 2000.

The County plans to continue to rely on the two landfills for disposal of municipal solid waste into the 21st Century. However, emissions from these landfills are currently and appear likely to remain essentially unregulated for a substantial period of time. Although minimum federal regulatory efforts have been initiated, those regulations are still preliminary and are not expected to be final until Spring 1995. When the regulations do become final, they will not require compliance for gas collection and control standards for almost four years thereafter. Thus, assuming the EPA issues final regulations in 1995, landfills would not have to comply until 1999. Postponement of landfill gas emissions controls until the new millennium will significantly impair the ability of Maryland to meet the 1996 CAA deadline for reduction of smog-forming VOC emissions by 15% from 1990 levels. Not only will the VOCs from landfills, which contribute significantly to total VOC emissions, remain unregulated, but VOC emissions from other stationary and area sources which are already stringently controlled will have to compensate for this deficiency.

Perhaps more important, however, the sizable populations living in close proximity to the Sandy Hill and Brown Station Road landfills must await a further 4 years or more before landfill gas emissions affecting their neighborhoods will be aggressively and effectively controlled.

TABLE A. 1990 Census Data for Sandy Hill[79] and Brown Station Road[80]



Sandy Hill			
	Radius in Miles		
	0.50 miles	1 mile	5 miles
Population	3135	4822	122,544

1 Emissions estimated using EPA Landfill Air Emissions Estimation Model Version 1.1. Individual HAPs and their concentrations are based upon based upon AP-42 values. Results rounded to one decimal place or first non-zero.

2 Hazardous Air Pollutant as defined in § 112(b) CAA (1990). *BOLD Italics* indicates suspected or confirmed animal or human carcinogen based on Sax & Lewis, Dangerous Properties of Industrial Materials, 7th edition.

3 Quantity of HAP generated within landfill.

4 Quantity of HAP not collected by collection system.

5 Quantity of HAP not destroyed by control device.

6 Uncollected plus residual HAP emissions. BOLD exceeds pertinent HAP threshold under 1990 CAA. Single HAP threshold is 10 TPY and combined HAP threshold is 25 TPY.

7 Based on Section A which is no longer accepting waste and which is scheduled to be capped by 1997, and Section B, the horizontal expansion, which is anticipated to close in 2017.

1 Hazardous Air Pollutant as defined in § 112(b) CAA (1990).

2 Quantity of HAP generated within landfill.

3 Quantity of HAP not collected by collection system.

4 Quantity of HAP not destroyed by control device.

5 Uncollected plus residual emissions.

. EPA PROPOSES CONTROLS OF LANDFILL GAS The Environmental Protection Agency proposed rules yesterday that would control emissions of air pollutants from large landfills that cause smog and could be contributing to global warming.

The standards and guidelines, which would be administered by the states, would apply to landfills that are designed to handle at least 100,000 metric tons of solid waste and that emit 150 metric tons or more of such organic compounds as benzene and vinyl chloride.

Those landfills would have to install gas collection and control systems.

The rules would control more than three-fourths of the 255,000 metric tons of nonmethane organic compounds emitted each year from landfills, the EPA said. Methane is not directly targeted, but the regulations would have the effect of controlling more than half the 10.5 million metric tons of methane emitted each year.

Methane is among the ""greenhouse" gases that many scientists believe may cause the Earth's climate to become much warmer during the next century.

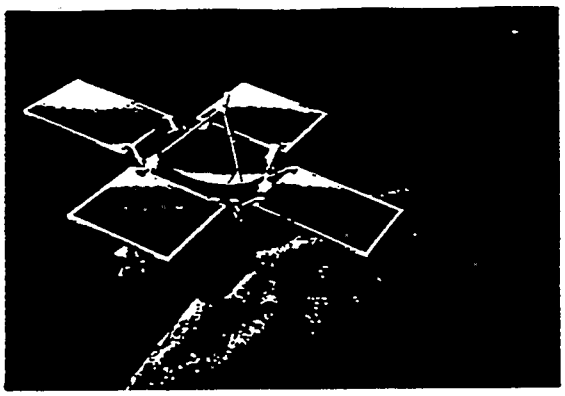
Developments to Watch

EDITED BY NEIL GROSS



DRAM CHIPS ARE GETTING EVEN SMARTER

A CHIP-DESIGN WIZARD WHO left Toshiba Corp. six years ago has figured out how to cram 6 to 10 times more information into memory-chip cells. The advance could slash the cost of DRAM (dynamic random-access memory) chips by two-thirds or more, says the inventor, Tamio Saito, who is co-founder, president, and CEO of Solidas Corp., based in San Jose, Calif.

Ordinary memory cells store just one bit of data. A high voltage in the memory cell's charge-storing capacitor means the bit is a one; a low voltage means it's a zero. But Saito's so-called ZRAM memory cells are sensitive enough to distinguish tiny differences in voltage—up to 1,000 increments from zero to five volts. Each of those voltage levels stands for a different string of bits—for instance, 0000000000 or 1010101010.

Saito succeeded in using multiple voltage levels by fixing a problem that plagued Toshiba, Hitachi, IBM, and others that have tried multilevel DRAMs—namely, electrical "noise" that distorts the voltage levels. Much of the noise comes from the slamming of the memory cell's transistor gate. So Saito gave each cell a second transistor that works in an opposite way, canceling the noise.

While Saito has achieved ... bits per cell in the lab, DRAM makers might settle for only six bits per cell in the first generation of mass production. That could be handled with just 64 different voltage levels. Memory access is slightly slower than in a conventional DRAM but fast enough for things such as video buffers and hard-disk controllers. Saito says Solidas is negotiating with five major DRAM makers interested in obtaining manufacturing licenses.

SURFING THE SKIES ON THE INTERNET

ASTRONOMERS PEERING INTO THE HEAVENS ARE GETTING a boost from another kind of space—cyberspace. At Lawrence Livermore National Laboratory, researchers capture images of mysterious, short-lived bursts of gamma rays in space. Their telescope takes good pictures but may not be looking where bursts are likely to occur. So astronomers rely on an orbiting observatory. It finds the bursts and alerts a ground station in Maryland, where computers calculate the coordinates and relay them to Livermore over the Net.

Livermore isn't alone. In October, responding to a tip on the Internet, scientists at the University of California's Lick Observatory made the first confirmed spotting of a planet outside our own solar system. And next year, scientists at the Johns Hopkins University Applied Physics Laboratory in Laurel, Md., will use a linked constellation of home pages on the World Wide Web to keep scientists around the world posted on its Near Earth Asteroid Rendezvous (NEAR), a collaboration with NASA. At the rendezvous, expected in June, 1997, NEAR will make the first comprehensive measurements of an asteroid's composition and structure (artist's concept above).

A VIRTUAL LAB THAT TURNS UP REAL-LIFE DRUGS

IN THEIR NEVER ENDING search for new drug candidates, pharmaceutical companies are increasingly turning to "combinatorial" chemistry. The idea is to combine molecular building blocks in different ways, thus synthesizing thousands of new chemicals. Each molecule can then be tested for drug-like effects.

Unfortunately, this shotgun approach doesn't always result in a drug candidate. That's why Exton (Pa.) startup 3-Dimensional Pharmaceuticals Inc. has come up with a new twist. In its approach, which just won a broad patent, computers first make "virtual chemicals," then search for those that have simulated biological effects. Since the computer isn't always right, the company then actually makes those promising chemicals. Tests of these substances, in turn, offer new data about the relationship between structure and biological activity, which can be used to fine-tune the chemicals in later rounds of synthesis.

3-D has used the method to find a promising anticlotting compound and now hopes to forge alliances with pharmaceutical partners.

HOW TO MAKE LANDFILLS LESS FUNKY

FOUL-SMELLING GASES from municipal landfills or composting operations aren't just a nuisance for people nearby. They can also cost operators a fortune to control. The solution, according to Cornell University researchers, is to use signature gases that form before the noxious fumes are released as an alarm system.

In most cases, the stench comes from bacteria that break down buried proteins, emitting culprits such as methanol and dimethylsulfide. Before this happens, however, carbohydrates in the mix tend to ferment, releasing odorless gases such as hydrogen and carbon monoxide. So the Cornell team built a pilot composter fitted with a gas-measuring device and studied the timing of different emissions. Using their observations, compost operators can pump air into the mix as soon as the odorless gases appear and reduce bacterial activity before bad fumes form.

2. HEALTH AND WELFARE EFFECTS OF AIR EMISSIONS FROM MUNICIPAL SOLID WASTE LANDFILLS

2.1 INTRODUCTION

This chapter presents a summary of the potential adverse health and welfare effects of air emissions from municipal solid waste (MSW) landfills. The five major effects of MSW landfill air emissions are (1) human health and vegetation effects caused by ozone formed from nonmethane organic compound (NMOC) emissions, (2) carcinogenicity and other possible noncancer health effects associated with specific MSW landfill emission constituents, (3) global warming effects from methane emissions, (4) explosion hazards, and (5) odor nuisance. In addition, soils and vegetation on or near the landfills are adversely affected by MSW landfill emissions migrating through the soil. The above effects are briefly summarized below and in Table 2-1.

A variety of different NMOCs have been detected in air emissions from MSW landfills. In the atmosphere, NMOCs can contribute to formation of ozone through a series of photochemical reactions. The ozone formed through these reactions can exert adverse effects on human health and on vegetation. The effects ozone exerts on both human health and vegetation are discussed in greater detail in Section 2.2.

There are potential acute and chronic health hazards associated with several chemical species in MSW landfill emissions. The potential cancer risks associated with exposure to MSW landfill emissions have been considered by EPA (see Section 2.3). There are also other chronic noncancer health effects associated with some of the individual chemicals found in MSW landfill air emissions. Qualitative descriptions of both the cancer and noncancer health effects are also included in Section 2.3.

The landfill gas that is generated from the decomposition of municipal solid waste in a landfill consists of approximately 50 percent methane and 50 percent carbon dioxide, and less than 1 percent NMOCs. The methane emissions are of concern for two reasons: 1) methane, one of the "greenhouse gases", contributes to the phenomenon of global warming

TABLE 2-1. SUMMARY OF THE HEALTH AND WELFARE EFFECTS ASSOCIATED WITH MSW LANDFILL EMISSIONS AND COMPONENTS

Component	Health and welfare effects
Ozone	Alterations in pulmonary function, aggravation of pre-existing respiratory disease, damage to lung structure; foliar injury, such as stippling or flecking, reduced growth, decreased yield
Toxics	Leukemia, aplastic anemia, multiple myeloma, cytogenic changes, damage to liver, lung, kidney, central nervous system, possible embryotoxicity, brain, liver and lung cancer, possible teratogenicity
Methane	Death, burns, dismemberment due to explosions and fires; property damage; contribution to phenomenon of global warming; MSW landfill emissions migrating through the soil on or near the landfill inhibits revegetation, causing deep root death
Odor	Odor nuisance, leading to annoyance, irritability, tension, reduction in outdoor activities, reduction in property values, decreased commercial investment leading to decreased sales, tax revenue

(Section 2.4; and 2) the accumulation of methane gas in structures both within and beyond the landfill boundary has resulted in explosions, fires, and subsequent loss of property (Section 2.5).

Pollutants that exert effects on human welfare are pollutants that affect the quality of life, cause damage to structures, or result in a loss of vegetation. The welfare effects of concern associated with MSW landfill air emissions include, in addition to destruction of property by explosions, emanation of odors and effects on soil and vegetation. Although odor perception is extremely variable and subjective, sociological studies have shown extreme annoyance and emotional disturbances in individuals residing in areas where objectionable odors are present. Property values may decrease and economic disadvantages may result in communities in or near a source of perceived malodorous emissions such as those from MSW landfills. Section 2.6 discusses odor generation by MSW landfills and some of the studies and surveys that have been done about the problem of odor nuisance. Also, revegetation of uncontrolled landfills after closure is often unsuccessful because the landfill gases affect plant root structure. This effect is discussed in Section 2.7.

2.2 EFFECTS ON HUMAN HEALTH AND VEGETATION CAUSED BY AMBIENT OZONE FORMED FROM NONMETHANE ORGANIC EMISSIONS

2.2.1 Health Effects Associated with Exposure to Ozone

Ozone and other oxidants found in ambient air are formed as the result of atmospheric physical and chemical processes involving two classes of precursor pollutants, NMOCs and nitrogen oxides (NO_x). NMOCs are constituents of the air emissions from MSW landfills. Therefore, emissions of NMOCs from landfills also contribute to ozone formation. The effects of ozone on human health are well documented. There are several different mechanisms through which ozone can exert adverse effects on human health. Ozone can penetrate into different regions of the respiratory tract and be absorbed through the respiratory system. Indirect effects of ozone are those such as adverse effects on the pulmonary system resulting from chemical interactions of ozone as it progresses through the system. Finally there may be adverse effects on other body organs and tissues caused indirectly by reactions of ozone in the lungs.

Specific adverse human health effects associated with exposure to ozone include:[2]

- changes in pulmonary function;
- symptomatic effects;
- aggravation of pre-existing respiratory disease;
- damage to the lung structure;
- increases in susceptibility to respiratory infections; and
- adverse effects on blood enzymes, central nervous system, liver and endocrine system.

Pulmonary function decreases have been reported in healthy adult subjects after one to three hours of exposure to ozone. Subjects at rest (not exercising) have shown decreases in lung function at concentrations of about 0.5 ppm ozone.[3] Persons that are heavily exercising have experienced decreases in lung function at about 0.1 ppm ozone.[4]

Symptomatic effects, such as cough, shortness of breath, general trouble in breathing and pain when breathing have been reported in controlled human exposure studies. These effects reportedly occurred when exposure levels exceeded an ozone concentration of 0.12 ppm.[5]

There is some indication from a group of epidemiological studies that persons with existing respiratory diseases may experience aggravation of their conditions when exposed to ozone. Definitive data correlating increased rates of asthma attacks to ozone exposure do not exist, however.[6]

Another possible effect of ozone exposure is damage to the lung structure. Laboratory studies of rats and monkeys have shown inflammation and damage to lung cells following exposure to ozone. Studies on rats, mice, and rabbits have shown increased susceptibility of the animals to bacterial respiratory infections following ozone exposure.[7] Considering the differences in human and animal physiology and immune defenses, it is still reasonable to hypothesize that humans exposed to ozone could experience increased susceptibility to respiratory infections.[8]

Finally, some animal studies have indicated that exposure to ozone exerts adverse effects on the cardiovascular, liver and endocrine systems. Definitive data on humans to substantiate these occurrences are not available. However, the body of evidence from the animal studies suggests that ozone can cause effects in tissues and organs other than the lung.[9]

2.2.2 Adverse Effects of Ozone on Vegetation

Foliar injury on vegetation is one of the earliest and most obvious manifestations of ozone impacts. The specific effects can range from reduced plant growth and decreased yield, to changes in crop quality and alterations in susceptibility to abiotic and biotic stresses. The plant foliage is the primary site of ozone effects, although significant secondary effects, including reduced growth and yield, can occur. Ozone injury to foliage is identified as a stippling or flecking. Such injury has occurred experimentally in various plant species after exposure to 60 $\mu g/m^3$ (0.03 ppm) ozone for 8 hours.[10] Studies with tobacco and other crops confirmed that ozone injures vegetation at sites near urban centers.[11] It is now recognized that vegetation at rural sites may be injured by ozone that has been transported long distances from urban centers.[12] Studies of the effect of ozone on plant growth and crop yield indicate occurrences of detrimental effects. For example, field studies in the San Bernatino forest during the last 30 years show that ambient ozone has reduced the height growth of Ponderosa pine by 25 percent and has reduced the total volume of wood produced by 84 percent.[13]

2.3 CANCER AND NONCANCER HEALTH EFFECTS

The adverse human health effects associated with MSW landfill emissions have not been directly determined by human or animal studies. In the absence of such data, EPA has evaluated some of the individual chemical constituents of MSW landfill emissions. Over 100 chemical constituents have been detected in MSW landfill emissions, as shown in Table C-1 of Appendix C. Exposure to the several of the landfill constituents has been associated with cancer and noncancer health effects. Both cancer and noncancer health effects have not been quantified in a national study, due to limitations in the emissions data. However, these adverse effects can be discussed qualitatively. Adverse effects on target organ systems such as the kidney, liver, pulmonary, and central nervous systems have been

associated with various components of air emissions from MSW landfills. A detailed summary of the health effects is given in in Section 2.3.1.2.

2.3.1 Hazard Identification

Hazard identification is a qualitative step for determining whether or not exposure to a given substance is associated with any adverse health effect. Because epidemiological and animal studies of the health effects of MSW landfill emissions, which are mixtures of many chemicals, have not been found, the hazard identification process was based on a review of the health data of the MSW components. This review focused on nine carcinogenic constituents known to be present in MSW landfill air emissions (benzene, carbon tetrachloride, chloroform, ethylene dichloride, methylene chloride, perchloroethylene, trichloroethylene, vinyl chloride, and vinylidene chloride--Table 2-2). There were other carcinogenic compounds emitted, but these nine pollutants have been repeatedly measured in the air emissions from various MSW landfills.

One of the initial steps that EPA takes in addressing the potential for health effects is to consider the quality of the available data for each MSW landfill gas constituent. The EPA has developed a classification scheme for characterizing the weight-of-evidence for human carcinogenicity. Evidence of possible carcinogenicity in humans comes primarily from two sources: long-term animals tests and epidemiologic investigations. Results from these studies are supplemented with available information from other relevant toxicologic studies. The question of how likely an agent is to be a human carcinogen is answered in the framework of a weight-of-evidence judgment. Judgments about the weight of evidence involve considerations of the quality and adequacy of the data and the kinds and consistency of responses induced by a suspect carcinogen. There are three major steps to characterizing the weight-of-evidence for carcinogenicity in humans: (1) characterization of the evidence from human studies and from animal studies individually, (2) combination of the characterizations of these two types of data into an indication of the overall weight-of-evidence for human carcinogenicity, and (3) evaluation of all supporting information to determine if the overall weight-of-evidence should be modified.

TABLE 2-2. SUMMARY OF THE HEALTH EFFECTS ASSOCIATED WITH TOXIC MSW LANDFILL EMISSIONS COMPONENTS

Component	Health and welfare effects
Benzene	Leukemia, aplastic anemia, multiple myeloma, cytogenic changes--human carcinogen
Carbon tetrachloride	Damage to liver, lung, kidney, central nervous system. Possible embryotoxicity--probable human carcinogen
Chloroform	Damage to liver, kidney, central nervous system--probable human carcinogen
Ethylene dichloride	Damage to central nervous system--probable human carcinogen
Methylene chloride	Probable human carcinogen
Perchloroethylene	Probable human carcinogen
Trichloroethylene	Probable human carcinogen
Vinyl chloride	Central nervous system effects; brain, liver and lung cancer; possible teratogen--human carcinogen
Vinylidene chloride	Damage to liver, kidney--possible human carcinogen

The EPA has developed a system for stratifying the weight-of-evidence. This classification is not meant to be applied rigidly or mechanically. At various points in the above discussion, there is the need for an overall, balanced judgment of the totality of the available evidence. Particularly for well-studied substances, the scientific data base will have a complexity that cannot be captured by any classification scheme. The EPA's weight-of-evidence system is summarized in Table 2-3 and the specific weight of evidence classifications for the nine carcinogens of concern are provided in Section 2.3.2.[14]

2.3.2 Health Effects of Individual Compounds

A discussion of the adverse health effects and the weight evidence classification for the nine carcinogens is presented below.

2.3.2.1. Benzene. Benzene administered orally to rats has resulted in increased incidences of Zymbal gland carcinomas.[15] In mice, inhalation exposures have shown subsequent anemia and other disorders of the blood forming tissues.[16] Other studies with mammalian cells have shown cytogenic abnormalities following benzene exposure.[17]

In humans, chronic exposure to benzene has resulted in abnormalities of the blood such as anemia, leucopenia, thrombocytopenia (pancytopenia). Epidemiological studies have shown highly statistically significant causal associations between leukemia and occupational exposure to benzene and benzene-containing solvents.

Other studies of human populations exposed to benzene have shown significant increases in chromosomal aberrations. In some instances, the aberrations have persisted for years after the cessation of exposure.[18]

According to IARC, there is sufficient evidence that benzene is a human carcinogen and limited evidence that it is carcinogenic in experimental animals.[19] EPA classifies benzene as a Group A carcinogen, a human carcinogen. The Group A classification is used only when there is sufficient evidence from human studies to support a causal association between exposure to a given substance and induction of cancer.

TABLE 2-3. CLASSIFICATION OF EVIDENCE BASED ON ANIMAL AND HUMAN DATA[a,b]

	Animal Evidence				
Human evidence	Sufficient	Limited	Inadequate	No data	No evidence
Sufficient	A	A	A	A	A
Limited	B1	B1	B1	B1	B1
Inadequate	B2	C	D	D	D
No data	B2	C	D	D	E
No evidence	B2	C	D	D	E

[a] The above assignments are presented for illustrative purposes. There may be nuances in the classification of both animal and human data indicating that different classifications than those given in the table should be assigned. Supporting data (e.g., structure-activity relationships, short-term test findings, etc.) should also be considered in the weight-of-evidence classification.

[b] A - human carcinogen
B2 - probable human carcinogen
C - possible human carcinogen
D - not classifiable as to human carcinogenicity
E - evidence of noncarcinogenicity for humans

2.3.2.2 Carbon tetrachloride. Carbon tetrachloride causes damage to the liver, lungs, kidneys and central nervous system in humans.[20] The potential for embryotoxicity exists, especially for males. The carcinogenicity of carbon tetrachloride has been observed in tests with three animal species. Primarily, the tumors found in the animals were liver tumors.[21] The human data on carcinogenicity of carbon tetrachloride are centered on case reports and one epidemiological study. Using the EPA weight of evidence criteria for carcinogenicity, carbon tetrachloride is classified as a probable human carcinogen, Group B2.

2.3.2.3 Chloroform. Exposure to chloroform has been associated with adverse effects on the liver, kidneys, and central nervous system of humans.[22] Additional effects on the human cardiac system have also been reported, including cardiac arrhythmias and cardiac arrest.[23] There is also some evidence that chloroform has carcinogenic potential in several animal species, including mice (eight strains), rats (two strains) and one strain of dogs. In these studies, chloroform was administered orally. The evidence for carcinogenicity of chloroform in animals includes statistically significant increases in kidney tumors in rats and mice, and liver tumors in mice.[24]

No epidemiological studies have been found evaluating chloroform by itself. But several studies have indicated small, but statistically significant increases in rectal, bladder and colon cancer in humans consuming drinking water that contained chloroform as well as other trihalomethanes. Because chloroform was not thought to be the only possible carcinogen in the drinking water, the studies cannot be used to define chloroform's carcinogenic potential in humans. At this time, the epidemiologic evidence for the carcinogenicity of chloroform is inadequate.[25] The overall weight of evidence classification for chloroform is B2--probable human carcinogen,[26] based on existing sufficient animal evidence and inadequate epidemiological evidence.

2.3.2.4 Ethylene dichloride. The adverse effects of ethylene dichloride (EDC) that have been reported in the literature are largely associated with the gastrointestinal and nervous systems in humans. Subtle neurological effects (e.g., fatigue, irritability, sleeplessness) may be

more prevalent than overt symptoms of central nervous system toxicity at lower concentrations.

EDC was shown to be carcinogenic in a National Cancer Institute lifetime bioassay. Several types of tumors were observed in both rats and mice. In rats, carcinogens of the forestomach and circulatory system hemangiosarcomas were found. Hepatocellular carcinomas, alveolar/bronchiolar adenomas, and mammary carcinomas were seen in mice exposed to EDC.[27] The route of exposure for this bioassay was gavage (oral). No statistically significant increases in tumors occurred in rats or mice following lifetime inhalation exposure.[28] No case reports on studies in humans concerning carcinogenicity of EDC were found in the literature.[29]

The weight of evidence classification for EDC is B2, meaning it is a probable carcinogen in humans.[30] The classification is based on sufficient animal evidence from the lifetime oral exposure bioassay along with an absence of epidemiologic data.

2.3.2.5 Methylene chloride. Bioassays conducted by the National Toxicology Program (NTP) demonstrated that methylene chloride is oncogenic (tumor-causing) in both rats and mice when exposed via inhalation. In the mouse bioassay, statistically significant increases in liver and lung tumors were observed.[31] Statistically significant increases in benign mammary gland tumors were seen in the rat bioassay.[32]

Data on humans exposed to methylene chloride, primarily in the workplace, are judged to be inadequate for evaluating the carcinogenic potential of methylene chloride. Therefore, methylene chloride is classified as a Group B2 carcinogen--probable human carcinogen--because there is sufficient animal evidence and inadequate epidemiological evidence.

There has been some difference of opinion on the carcinogenic potential of methylene chloride as related to species differences in metabolic pathways. The EPA has evaluated the latest data related to the risk of cancer and exposure to methylene chloride. The EPA has concluded that the evidence of the carcinogenic mechanism of methylene chloride and species differences in use of the metabolic pathways are not sufficient to support an estimate of zero cancer risk to humans.[33]

2.3.2.6 Perchloroethylene

In humans, transient liver damage has been linked to short-term exposures to perchloroethylene at relatively high levels. Some slight effects on the central nervous system have been reported in humans exposed to relatively high perchloroethylene concentrations.[34] Excluding carcinogenicity, toxicity testing in experimental animals, along with limited human data, suggest that long-term exposure to low concentrations of perchloroethylene is not likely to present a health concern.[35]

However, inhalation bioassays conducted by the National Toxicology Program on rats and mice of both sexes showed evidence of carcinogenicity for perchloroethylene.[36] In the National Toxicology Program studies, increases in mononuclear cell leukemia, and rare kidney tumors were observed in rats. Liver tumors were observed in mice.[37] Using the EPA weight of evidence classifications, perchloroethylene is considered a probable human carcinogen, Group B2.

2.3.2.7 Trichloroethylene. The evidence for carcinogenicity of trichloroethylene is shown by tumor induction in male rats and both sexes of mice by oral and inhalation exposure.[38] Statistically significant increases in renal adenocarcinomas and adenomas were observed in bioassays of male rats by either inhalation or oral exposures. Either exposure route produced elevated incidences of leukemia in one strain of male rats.[39] Inhalation exposure produced hepatomas and hepatocellular carcinoma (liver tumors) in two mouse strains. Inhalation exposure also produced malignant lymphomas in one strain of female mice.[40] Leydig cell tumors have also been reported in two studies.[41]

Epidemiological evidence for carcinogenic potential of trichloroethylene is inadequate. EPA reviewed seven epidemiologic studies or surveys and concluded all were inadequate to allow characterization of carcinogenic potential.[42]

EPA has classified trichloroethylene as a Group B2--probable human carcinogen.[43] This classification is based on the existence of sufficient animal evidence and inadequate epidemiological evidence.

2.3.2.8 Vinylidene chloride. Metabolism of vinylidene chloride produces substances (metabolites) that exert adverse effects on the liver and kidneys.[44] Eighteen animal studies were identified by EPA in the literature that provided information on the carcinogenic potential of vinylidene chloride. None of the studies that were conducted using the inhalation exposure pathway was conducted over the lifetime of the study animals.[45] In the single study that was judged to be adequate for assessing carcinogenic potential, statistically significant increases in kidney tumors were observed in one strain of male mice.[46]

There is no adequate epidemiologic evidence to assess the carcinogenicity of vinylidene chloride in humans.[47] Because there is limited animal evidence for carcinogenicity and inadequate evidence from epidemiological studies, EPA has classified vinylidene chloride as a Group C--possible human carcinogen.[48]

2.3.2.9 Vinyl chloride. In mice, exposure to vinyl chloride via inhalation has produced lung tumors, mammary carcinomas and angiosarcomas of the liver (malignant tumors). Cancer of the liver and other organs was also observed in rats exposed to vinyl chloride.[49]

In occupational exposures of humans, vinyl chloride disease is the name given to the total clinical syndrome associated with vinyl chloride exposure. The disease includes circulatory disturbances in the extremities (hands and feet), Raynaud syndrome, skin changes and changes in liver function.[50]

Other studies have shown chromosomal aberrations in the lymphocytes of humans occupationally exposed to vinyl chloride.[51] In addition, increased incidences of fetal loss have been associated with occupational exposure to vinyl chloride.[52]

Studies of humans exposed to vinyl chloride in the workplace have shown a causal relationship between the vinyl chloride exposure and development of cancer of the liver, brain and lung.[53] Angiosarcomas are rare tumors. Finding seven cases of these tumors in a single group of workers at one vinyl chloride plant is strong evidence of the carcinogenicity of vinyl chloride. Vinyl chloride is classified as a Group A carcinogen; a human carcinogen.

2.3.3 Cancer Risk Assessment

Based on the available information, EPA attempted to quantify the potential carcinogenic risks to the people exposed to MSW landfill emissions. However, unlike other source categories that have been regulated previously, the EPA was not able to quantify for this source category as one of the critical risk assessment parameters--toxics emissions rates. This was because the MSW landfill data base was generated by collecting available information from numerous sources which were not specifically designed to quantify toxics emissions rates. Although the data base of 931 facilities contained some data for the toxic constituent concentrations and the landfill gas emissions rates, there was no facility for which both values were known. Both the toxic constituent concentration and the landfill gas emission rate are required to compute the toxic emission rate. In addition, the EPA had no reliable technique to replace a missing value for either toxics emissions parameter from the other reported parameters in the database. Thus, the EPA could not reliably calculate a toxics mass emission rate and, in turn, could not reliably calculate a risk estimate for even one facility.

Other attempts, such as random assignment of known (measured) values to those facilities with missing values, were made to extrapolate nationwide risk estimates from the limited toxics data.[54] In doing so, this extrapolation (the estimation of the toxic landfill gas mass emission rates) was creating an additional level of uncertainty above and beyond a more typical risk assessment. After considering this additional uncertainty in conjunction with the other known uncertainties associated with risk assessment, the EPA concluded that MSW landfill risk estimates would not be credible. Furthermore, because these regulations are being proposed under Sections 111(b) and (d) of the Clean Air Act and are technology-based, risk estimates were not required in selecting among the regulatory options (see Chapter 5). However, even though the risk associated with exposure to landfill emissions could not be reliably quantified, the available information indicates that toxic emissions do emanate from MSW landfills and suggests a need to regulate this source category's emissions.

2.4 METHANE EMISSIONS CONTRIBUTING TO GLOBAL WARMING

Greenhouse gases serve to trap heat from the sun and maintain the earth's climate. Methane and other greenhouse gases such as carbon dioxide and nitrous oxide occur naturally in the atmosphere. They serve as a thermal blanket allowing solar radiation to pass through the atmosphere while absorbing some of the infrared radiation emitted back from the earth's surface. The absorption of radiation warms the atmosphere and provides the present climate. The earth would be approximately 30 degrees colder without the presence of greenhouse gases. The atmospheric temperature will increase if the concentrations of greenhouse gases are increased.[55-57]

Anaerobic decomposition of municipal solid waste in landfills results in the decomposition of municipal solid waste in landfills results in the generation of methane and carbon dioxide. An estimate of the amount of methane and carbon dioxide from MSW landfills is provided in Chapter 3. Methane is more potent than CO_2 due to its radiative characteristics and other effects methane has on atmosphere chemistry. Molecule-for-molecule methane traps 20-30 times more infrared energy in the atmosphere. Therefore even a small increase in the methane concentration in the atmosphere is a concern to scientists trying to predict the warming of the climate.[58-60]

There is considerable uncertainty with regard not only to the timing but also to the ultimate magnitude of any global warming. However, there is currently strong scientific agreement that the increasing emissions of greenhouse gases such as methane will lead to temperature increases. Within EPA and the international scientific community efforts are underway to reduce these uncertainties, estimate the cost of mitigation, and identify possible control options. Reduction of methane emissions from MSW landfills is one of many options available to reduce possible global warming.

2.5 EXPLOSION HAZARDS

2.5.1 Health Effects Associated with the Explosivity Of Municipal Solid Waste Landfill Air Emissions:

Decomposition of the waste in MSW landfill air emissions produces the explosive methane gas. If the methane accumulates in structures on or off-site, explosions or fires can result. MSW landfill air emissions have

resulted in documented explosions and fires both within and beyond the landfill boundaries. Section 2.5.2 of this chapter describes the welfare effects such as the explosion hazards and associated property damage. This section briefly presents information on the health effects associated with the explosions resulting from MSW landfill gas emissions.

MSW landfill gas can migrate off-site and emissions can escape into confined spaces such as basements, crawl-spaces, utility closets and false ceilings. Explosions of the gas have caused severe personal injury and death. Table 2-4 lists documented cases of acute injury and death caused by explosions and fires related to MSW landfill gas emissions.

2.5.2 Explosivity of MSW Landfill Air Emissions

MSW landfill gas is composed largely of methane and carbon dioxide. Methane gas is odorless and is highly explosive when mixed with air at a volume between 5 and 15 percent (the lower and upper explosive limits of methane). Methane can migrate off-site from the landfill and possibly collect in basements or crawl spaces of nearby structures. For example, methane has migrated from the Port Washington landfill in New York into homes near the landfill. Within two years, four explosions occurred in homes very near the landfill. Subsequent testing by the Nassau County Fire Marshall discovered explosive levels of methane in or around twelve homes in the vicinity of the landfill.

Table 2-5 lists documented examples of explosions or fires associated with MSW landfill gas. These examples show clearly that structural damage and the loss of facility use are real possibilities related to these gas explosions. Instances of facility abandonment are also documented as shown in the table.

There is also documentation that the presence and migration of MSW landfill emissions adversely affects property value of surrounding land parcels. For example, at the Midway landfill in the Seattle, Washington, area, MSW landfill gas migrated under a major interstate highway and percolated up in residential areas. There was immediate concern in the neighborhood; 11 families were evacuated.[61] A program to subsidize the sale of houses in the area was started by the City. Information collected

TABLE 2-4. ACUTE INJURY AND DEATHS ASSOCIATED WITH MUNICIPAL LANDFILL AIR EMISSIONS EXPLOSIONS AND FIRES[a]

Location, date	Incident, injury[b]
Comack, NJ. 1984	Gas migrated to landfill weigh-station on-site. Explosion killed one, injured one.
Manchester, NJ. 1983	Spark from landfill pump probably ignited gas. One person burned.
Cleveland, OH. 1980	Explosion at foundry adjacent to landfill. One killed.
Commerce City, CO. 1977	Explosion in tunnel being built under a railroad right-of-way. Two workmen killed, four firemen injured.
Sheridan, CO. 1975	Gas migrated into drainage pipe under construction. Welding truck led to fire. Two injured.
Sheridan, CO. 1975	Gas accumulated in drain pipe running through landfill. Children playing with candle caused explosion. Several children injured.
Richmond, VA. 1975	Gas migrated from nearby landfill into apartment. Two injured.
Winston-Salem, NC. 1969	Gas migrated from adjacent landfill into basement of armory. Lighted cigarette led to explosion. Three killed, five seriously injured.
Atlanta, GA. 1967	Gas migrated from adjacent landfill into sealed basement of single story recreation center building. Lighted cigarette led to explosion. Two workmen killed, six injured.
Madison, WI (no date given)	Explosion destroyed sidewall of a townhouse. Two people seriously injured.

[a]Reference 62.

[b]These incidences highlight explosions and health effects. Other incidences of explosions related to methane migration from MSW landfills and property destruction are given in Table 2-6.

TABLE 2-5. DOCUMENTED CASES OF LANDFILL GAS MIGRATION AND ASSOCIATED FIRES AND EXPLOSIONS[a]

Landfill name/location/date	Damages and other comments
Pittsburgh, PA September 1987	Offsite gas migration is suspected to have caused house to explode. Incident is under investigation. Toxics are being monitored in homes near the landfill.
Bakersfield Landfill Fresno, California April 1984	Fresno police bomb squad used site for practice. A bomb was buried and was detonated causing LFG explosion. Explosive levels of methane were also migrating off-site.
BKK Landfill West Covina, California August-October 1984	Twenty residences temporarily evacuated due to explosive methane levels in adjoining soils.
Babylon Landfill Comack, New Jersey May 1984	Methane migrated to a house on-site and exploded.
Hardy Road Landfill Akron, Ohio 1984	One house destroyed. Ten houses evacuated temporarily.
I-95 Landfill Lorton, Virginia 1984	Explosion and fire occurred.
Landfill near Lake Township Canton, Ohio 1984	Two homes and a day care center temporarily evacuated.
PJP Landfill Jersey City, New Jersey 1984	Landfill fires causing air pollution have been a continual problem.
Smithtown Landfill Smithtown, New York 1984	Explosion damaged room in transfer station.

(continued)

TABLE 2-5. (Continued)

Landfill name/location/date	Damages and other comments
Wallingford Landfill Wallingford, Connecticut June 1984	Explosive levels of methane detected in dog pound. Dog pound temporarily closed, ventilation system to be installed.
Anderson Township Landfill Cincinnati, Ohio 1983	Explosion destroyed residence across the street from the landfill. Minor injuries reported.
Monument Street Landfill Baltimore, Maryland April 1983	Vent pipes were not maintained causing vents to become nonfunctional. Street light fire was believed related to methane migration. Ongoing lawsuit concerns presence of priority pollutants.
Ocean County Landfill Manchester, New Jersey December 1983	Spark from landfill pump probably ignited methane gas, causing explosion and fire. Office building destroyed.
Operating Industries Landfill Monterey Park, California August 1983	Vinyl chloride detection caused SCAQMD to order 30-day shutdown of landfill. It reopened, subject to closure in 6 months.
Shawnee County Landfill Topeka, Kansas August 1983	Home abandoned due to high methane levels.
Falls Street Landfill Richmond, Virginia 1975	In 1975, explosion occurred in nearby apartment building. The city decided to buy and demolish it. Two schools sited on the landfill were closed until a control system was installed.
Tyler, Texas May 1982	TDPS office building sited on closed landfill. Methane has caused problems since early 1970's. Failure of ventilation exhaust fan resulted in "significantly high" levels of methane in the building.

(continued)

TABLE 2-5. (Continued)

Landfill name/location/date	Damages and other comments
Mission Avenue Oceanside, California 1981	Schools surrounding the landfill were evacuated and classes were suspended for 4-5 months.
Port Washington Landfill North Hempstead, New York 1981	Explosions in furnace rooms of several homes. Minor damage occurred. Furnaces were replaced.
Beantown Dump Rockville, Maryland 1980	Small explosion occurred in enclosed back room of auto body shop. Shop closed for 1 month until control system was installed.
Warner Hill Landfill Cleveland, Ohio 1980	Explosion killed foundry worker on site adjacent to landfill.
Reilly Construction Company Springfield, Illinois 1979	Methane migrated into construction company offices adjacent to the landfill. Limited fires occurred No explosion. Building evacuated and use restricted for 4 weeks.
Allegheny County Landfill Frostburg, Maryland 1978	Limited fire in off-site equipment maintenance building. No explosion. Building use restricted for 2 months. Building was highly ventilated until gas control system installation.
Campground Landfill Louisville, Kentucky 1978	No physical damages occurred. Buildings evacuated for short period of time.
Lees Lane Landfill Louisville, Kentucky 1978	Small fires and explosions. Several houses evacuated and condemned. Benzene (29.5 ppm) and vinyl chloride (17.9-122.6 ppm) detected off-site.
Unnamed Landfill Adams County, Colorado	Explosion at a construction project adjacent to the landfill.

(continued)

TABLE 2-5. (Continued)

Landfill name/location/date	Damages and other comments
Falls Street Landfill Richmond, Virginia 1982	The 1982 incident occurred when children trespassed onto the landfill site, entered a control system manhole, and lit a match, resulting in an explosion.
Winston-Salem, North Carolina 1969	Methane migrated into National Guard Armory.
Greentree Hills Landfill Madison, Wisconsin	Explosion blew out one sidewall of a townhouse. Three adjacent apartment buildings and several homes evacuated for 20-30 days. Claims filed against the city total $5.2 million dollars.

[a]References 63,64.

on property values recorded during the operation of the program indicated a decrease of 5 to 10 percent in residential property value.

2.6 ODOR NUISANCE

Odors are frequently associated with air emissions from MSW landfills. Odors escape along with MSW landfill gas from surface cracks in the landfill. As waste is added to the landfill, disturbances of soil layers can also provide a means of escape for odors. Individuals vary in their ability to detect odors and in the degree of pleasantness or unpleasantness they experience with various odors.[65] However, the types of odors generally associated with the decomposition of organic material that occurs at landfills are most likely to be unpleasant or objectionable. This section describes the occurrence of odors at MSW landfills, and lists examples of the types of odorous compounds likely to emanate from landfills. The section also describes how odors affect human welfare by the unpleasantness of the odors themselves, by possibly lowering the property value of real estate near a MSW landfill, and by the potential for odors to cause properties to be abandoned and therefore leading to loss of facility and property use.

2.6.1 Odor Generation

Municipal landfill gas is generated largely by bacterial decomposition of organic materials in the municipal solid waste. As the decomposition proceeds, odiferous compounds can escape from the landfill through cracks in the landfill surface cover.

Other possible sources of odors associated with air emissions from MSW landfills are the actual wastes themselves. Household wastes that are often disposed in MSW landfills include chemicals in cleaners, paints, pesticides and adhesives. These consumer products often contain solvents or other compounds with distinctive odors. As these household products are added to a landfill, the odors associated with some of these chemicals may be noticeable to nearby residents or passersby. These odors may also emanate on a continuing basis from cracks in the landfill surface cover.

2.6.2 Adverse Effects of Odors on Human Welfare

The influence of odors on the comfort and welfare of individuals is difficult to prove. Odors can result in social and behavioral changes in an exposed population. However, odor perception and impact is subjective. Different individuals may react differently to the same type and intensity of odor. Therefore, it is difficult to quantify a degree of unpleasantness associated with different odors. The descriptions in this section on the adverse effects of odors on human welfare are necessarily qualitative.

A few studies in the United States and the Federal Republic of Germany have investigated the social and behavioral effects of odors on the population. These studies have indicated that annoyance is a common reaction of residents in communities where unpleasant odors are encountered. Examples of responses from a survey of 704 residents of Dusseldorf are shown in Table 2-6. In the U.S., studies have indicated that odors have interfered with daily activities. U.S. studies are generally older and not quite as specific as other studies in the literature.[66]

It seems likely that the presence of odors would also exert the same type of detrimental effect on property value. At this time, the effect cannot be quantified. As was discussed earlier in relation to explosivity, property values around the Midway landfill in the Seattle area decreased from 5 to 10 percent with increased awareness of the presence of MSW landfill gas. The decreases could not be directly correlated to odors associated with the landfill.

Odors can also cause temporary or perhaps permanent loss of facility use. Although specific studies were not found that documented any loss of property use because of the odors from MSW landfills, it is possible that such adverse effects would occur. The responses shown in Table 2-7 indicate that odors can interfere in outdoor activities and interfere with the comfort of living. If a population perceives an odor as offensive and has questions about other possible effects beyond an annoying odor, the use of recreational or social facilities near the odor source may be greatly reduced or eliminated.

2.7 ADVERSE EFFECTS ON SOILS AND VEGETATION FROM MSW LANDFILL AIR EMISSIONS

The inability to grow vegetation or trees at MSW landfills is believed to be caused by one or more of the following factors: (1) lack of oxygen in the root zone; (2) toxicity of carbon dioxide to the roots; or (3) anaerobic

TABLE 2-6. RESPONSE COMPONENTS OF ANNOYANCE FACTORS DERIVED FROM A SURVEY OF 784 RESIDENTS OF DUSSELDORF[a]

Survey responses
Reduced social contacts
No pleasure in coming home
Odor leads to tensions within the family
Odor interferes with or disturbs communication
Odor spoils appetite
Odor interferes with comfort of living
Odor interferes with outdoor activities
Odor induces anger

[a]Reference 67..

conditions of the soil permitting the accumulation of reduced metals, such as iron (Fe), manganese (Mn) and zinc (Zn), in concentrations toxic to the vegetation.[68] Generally when landfill gases are present in the surface soil, the concentration increases at deeper soil layers. Thus, although the deeper rooted trees die, the shallow rooted ground vegetation continues to live. Diffusion of ambient air into the soil and diffusion of landfill gases out of the soil frequently result in the soils nearest the surface (top several inches) remaining in an aerobic condition, whereas the levels where the deepest roots are present can be anaerobic.[69]

According to the literature, there is a good deal of variability in tolerance to low oxygen in the root zone. The growth of red and black raspberries was inhibited by exposure to 10 percent oxygen, whereas apple trees required 10 percent oxygen in the soil in order to sustain growth.[70] Tomato plants grown in solution culture exhibited marked reduction in growth and ability to take up potassium (K) when exposed to three percent oxygen in the root zone.[71] Leone et al. reported that red maple, which is flood-tolerant, was also more tolerant of soil contaminated by simulated landfill gas than sugar maple, which is not tolerant of flooding.[72]

Greenhouse and field studies, and other research reported in the literature all confirm that the presence of landfill gases in the root zones of vegetation can be injurious to the extent of causing the death of vegetation. The major characteristics of landfill gas deleterious to plants when found in the root zone were the high carbon dioxide and methane and low oxygen concentrations resulting from anaerobic refuse decomposition.[73] Further studies indicate the extent of effects of landfill air emissions on vegetation. Various investigators have experienced difficulties in growing vegetation at completed or closed landfill sites. Stunting of corn and sweet potatoes became evident in areas adjacent to a New Jersey site where gases had migrated away from the landfill into the root zone of corn and sweet potato plants.[74,75] Death and poor growth of loblolly and other pines planted on such sites in southern Alabama have also been attributed to the presence of fermentation gases in the soil environment.[76] Poor tree growth in these areas has also been associated with lack of soil moisture and

ncreasing amounts of ammonia, nitrogen, iron, manganese, zinc, and opper.[77]

Closed refuse and fill sites at 15 locations in New Jersey, New York tate, metropolitan New York City, New England, Washington, Oregon, and labama were sampled both where vegetation was dead or dying and where the ame species were growing normally. Inspection of the contents of a soil ampling tube inserted to a depth of 20 cm in soil at sites where vegetation as dead or dying commonly revealed an anaerobic situation (dark, foul melling soil). Soil at sites where plant species were growing were commonly found to be in aerobic conditions. Instrument readings of methane (CH_4) and carbon dioxide (CO_2) were as high as 50 percent and 43 percent respectively, at the anaerobic sites.[78]

Soil tests at a closed landfill in central New Jersey showed that, 4 years after closure, the deepest 15 cm of a 60 cm soil cover was still distinctly anaerobic. The upper 45 cm of soil showed evidence of aerobic conditions; however attempts to establish herbaceous vegetation at the site demonstrated that only a few grass species ["reliant" hard fescue (Festuca longifolia Thull.), redtop (Agrostis alba L.) and sheep's fescue (F. ovina L.)] could survive under the undesirable soil conditions created by the landfill gases. Attempts to establish woody species also failed, even where grasses had been established.

Experimental work and site investigations have demonstrated an inability of the landfill cover to support and maintain vegetation, which also leads to increased erosion potential. If the cover is eroded, there is a chance that refuse will be exposed.. Opening the landfill cover could lead to contaminated runoff from the site, increased odor nuisance, and increases in rodent or vermin populations. According to CFR Part 60, this may be defined as an effect on public welfare.

EXH. 68

INTRODUCTION

In 1989, US EPA formally issued a national strategy for improved management of municipal solid waste (MSW).[1,2] This strategy, called "integrated waste management," features a hierarchy of techniques:

- **"Source Reduction"** (i.e., reduce the MSW generation rate and toxicity)
- **Recycling** (includes composting)
- **MSW Combustion** (with energy recovery)
- **Landfilling** (Waste that cannot be practically recycled or combusted must be landfilled, likewise for the residues resulting from MSW recycling, composting, and combustion.)

US EPA placed source reduction and recycling at the top of the hierarchy. Then, for that fraction of MSW that cannot be recycled practically, US EPA called for disposal by means of combustion, with recovery of energy. Landfilling was designated by US EPA for disposal of those waste types that cannot be recycled or combusted. US EPA's ranking of waste-to-energy is consistent with the preference of other advanced, industrialized countries. For example, Switzerland has banned by law the landfilling of untreated MSW; also, such landfilling will be significantly restricted by law in Germany this decade.[3,4]

US EPA noted that the four techniques above are complementary. No single management technique, by itself, is a panacea for waste management; rather, an appropriate mix must be tailored to local needs[2].

Notwithstanding US EPA's preferred waste-management hierarchy, the United States continues to embrace landfilling as its principal means of MSW management. According to US EPA's estimates of MSW disposal in 1990, this country landfilled two-thirds of its MSW, recycled only 17 percent, and combusted only 15 percent in waste-to-energy facilities[5]. The author is not aware of data showing a marked change since 1990 in the high landfill percentage. This disparity between US EPA's preferred hierarchy and actual practice is dramatically illustrated by the MSW management practices of the nation's most populous city, New York City. Residential waste there is collected predominantly by the City, and is disposed at the City's Fresh Kills Landfill.[6] The City currently buries about 4 million tons per year of MSW in its landfill,[6,7,8,9] and plans continued heavy reliance on this landfill for at least another decade, and likely well beyond.[9,10]

less than 1% non-methane organic compounds (NMOCs).[12] Methane, when mixed with air, is highly explosive, and has caused fires and explosions both within and beyond landfill boundaries.[13] Landfill gas can migrate subsurface, and accumulate in basements and other structures offsite.[13] US EPA notes that consequent explosions and fires "have caused severe injury and death."[13] US EPA compiled statistics on deaths, injuries, and property damage resulting from landfill-gas explosions and fires nationally, during the 20-year period, 1967 to 1987.[13] US EPA identified 20 incidents in 17 states in which gas migration resulted in explosions or fires *offsite*. Of those 20 incidents, US EPA documented eight incidents in which a total of nine members of the *public* were killed, and at least 20 were injured. Many of the other incidents, although not causing casualties, did result in property damage.

Most importantly, with regard to gaseous emissions from landfills, odor nuisance and explosion hazards are not the only concerns; gaseous emissions from landfills also contain air pollutants that pose a risk to human health and the environment. This will be documented below. The environmental importance of *air pollutant* emissions from MSW landfills is a "sleeper" issue. The public knows virtually nothing about air pollutant emissions from landfills, and state-level air quality regulators are generally only marginally aware of the issue. Because of this, the issue of air pollutant emissions from landfills has emerged as the principal subject matter of this paper.

As noted previously, landfill gas is comprised roughly of 50% methane and 50% carbon dioxide, and less than 1% of nonmethane organic compounds (NMOC). The air pollutants of concern are contained within the NMOC fraction. As summarized by US EPA,[12] the air pollutants present in landfill gas can be classified by their potential environmental effects:

- Ozone Nonattainment Precursors — Ambient ozone levels in excess of the National Ambient Air Quality Standards (NAAQS) adversely affect human health and damage vegetation.[14] Volatile organic compounds (VOC) are the principal precursor to ozone formation. US EPA has stated that landfill "NMOCs are primarily--VOCs contributing to the ozone nonattainment problem."[15] US EPA estimated NMOC emissions from MSW landfills nationwide to be 283,000 tons per year (TPY) in 1986, accounting for one percent of *all* NMOC emissions nationally from stationary emitters.[15] US EPA has also projected landfill NMOC emissions nationally to be 577,000 TPY by 1997.[16]

used to remove toxic pollutants from landfill gas. Collected gas can also be sold to an energy customer.

The overall efficiency of landfill gas control depends on what fraction of all gas generated by a landfill can be collected with a landfill gas collection system, and for that portion of gas that is collected, the control efficiency provided by the control device (e.g., flare or engine). US EPA stated that the efficiency of landfill gas collection systems has never been measured at any landfill,[23] and indicated a 50-60% efficiency is achievable for a well-designed system, based on limited available information.[24] In more recent draft guidance, US EPA has indicated a collection efficiency of 60-75% is possible[25]. This means that roughly one-quarter to one-half the gas generated in a landfill is likely *not* collected, and therefore, *not* controlled, but rather becomes uncontrolled, "uncollected" emissions to the ambient air. For that fraction of the landfill gas that is collected, US EPA believes that control devices (e.g., flares, engines) can achieve a 98% control efficiency for NMOC.[26] Conversely, this means that up to two percent of the collected gas passes through the control device without being controlled, and thus, represents a residual, uncontrolled emission. These residual emissions and the "uncollected" emissions described above are additive.

In the process of controlling the collected landfill gas, devices such as flares, engines, turbines, and boilers themselves generate air pollutant emissions,[27] referred to as "secondary emissions." Pollutants generated by these control devices include nitrogen oxides, (NO_x) carbon monoxide (CO), sulfur dioxide (SO_2), hydrogen chloride (HCl), carbon dioxide (CO_2), and particulate matter (PM),[27] as well as volatile organic compounds (VOC). In addition, there is specific technical evidence that these combustion devices produce and emit dioxin emissions as well.[28,29] Finally, heavy diesel equipment used on site to grade, compact, and cover landfilled MSW emits the same air pollutants.[30,31]

The key design requirement is directed towards groundwater protection, and necessitates, in most cases, a composite liner be placed below any new or expanded landfill unit, and that the leachate be collected. The Part 258 regulations also require monitoring wells to detect groundwater contamination. Should contamination by specified organic and metallic pollutants be detected, then corrective action is mandated.

The principal operating requirements include:

- Daily earthen covering of landfilled MSW
- Vector control
- Methane gas monitoring; corrective action if explosive levels are found
- Control of stormwater runoff
- Compliance with the State Implementation Plans (SIP), under the Clean Air Act

Finally, the regulations have landfill closure and post-closure provisions, namely a requirement for "capping" the closed landfill with an earthen layer, and for groundwater and methane gas monitoring for 30 years following closure. Many states began implementing these same types of requirements for landfills, well before US EPA promulgated national regulations.

While US EPA has formally promulgated regulations under RCRA that address the traditional environmental concerns with landfills, emissions from landfills of air pollutants covered by the Clean Air Act (and its amendments) remain not specifically regulated on a national level. What is more, states have not traditionally regulated landfill air pollutant emissions through their air quality control agencies either. In fact, US EPA searched and identified only one such state (California); 26 other states do regulate landfill air emissions, but under solid waste regulations.[33]

In 1991, US EPA took the first steps toward correcting this regulatory deficiency. US EPA issued proposed rules that would, for the first time, specifically regulate air pollutant emissions from landfills on a national basis.[34] In particular, US EPA proposed New Source Performance Standards (NSPS) for new MSW landfills under Section 111(b) of the Clean Air Act (CAA), and emissions "guidelines" for existing landfills under Section 111(d) of the CAA. US EPA's proposed standards of performance are based on its determination under Section 111 of the CAA that landfills constitute a category of stationary emission source which "...causes, or contributes significantly to air pollution which may reasonably be anticipated to endanger public health or welfare.[35]

Rate (LAER) controls, and emissions offsets. For existing facilities, requires Reasonably Available Control Technology (RACT).

- Maximum Available Control Technology (MACT) for HAPs – Title III of the 1990 CAAA. US EPA to promulgate MACT standards for MSW landfills by November, 1997.[39] MACT applies if a landfill emits any HAP in excess of 10 TPY, or multiple HAPs in aggregate exceeding 25 TPY. Of the over 100 toxic air pollutants EPA has documented to be present in landfill gas, a number are on the US EPA list of 189 HAPs regulated under Title III (acetaldehyde, acrylonitrile, benzene, ethyl acrylate, ethylchloride, ethylene oxide, formaldehyde, methanol, methyl chloride, phenol, propylene oxide, styrene, toluene, vinyl chloride, and xylenes).

- Federal Operating Permit – Title V of 1990 CAAA. Permit required for any emission source subject to the CAA.

US EPA and most state regulatory agencies presently do not require MSW landfills to comply with these requirements of the CAA and its 1990 amendments. Apparently, the technical basis for requiring compliance is not adequately recognized by regulatory agencies. The applicability of these provisions of the CAA will be demonstrated quantitatively below for the case of the landfill that serves New York City.

THE FRESH KILLS LANDFILL – NEW YORK CITY

In this section, the significance of landfill environmental emissions is illustrated for the case of the Fresh Kills Landfill in New York City. A quantitative demonstration is made that air pollutant emissions from that landfill are large enough to warrant serious scrutiny under the CAA and its 1990 amendments.

Landfill Description

As described by the New York City Department of Sanitation (NYCDOS), the Fresh Kills Landfill is the only MSW landfill serving the five boroughs of New York City.[40] The City has been disposing MSW in the Landfill since 1948.[40] Most of the City's residential MSW is collected by NYCDOS and disposed at the Fresh Kills Landfill.[6] Commercial MSW is collected privately in the City, and is exported from the City for disposal.[6]

April 1992; and #3, November 1993).[44] This supersedes previous Consent Orders executed in 1980 and 1985.

Some key requirements of the 1990 Consent Order (and its modifications) are as follows:[53]

- State Permit Applications – must be submitted to DEC by March 1995, for active portions of the Landfill, to include a solid waste permit (DEC "Part 360" permit), treated-leachate discharge permit (SPDES), and a tidal wetlands permit. The applicability of Federal and DEC air-permitting regulations was *not* addressed by the Consent Order.
- Daily Cover Requirements
- Litter Control Program
- Odor and Dust Control Programs
- Hydrogeological Study
- Long-Term Ground Water Monitoring Program
- Leachate Impact Study – on nearby surface waters and the sediment below
- Long-Term Surface Water Monitoring Program
- Leachate Collection and Treatment System – for the active sections of the Landfill, intended to collect at least 80% of the leachate.
- Landfill Gas Monitoring Program – to ensure gas does not reach explosive limits
- Landfill Gas Control System
- Ambient Air Monitoring – co-funding a DEC monitoring program to characterize the impact of air pollutant emissions from the Landfill on Staten Island's air quality. (Consent Order Modification #2)
- Closure Designs – for all Landfill sections

	Maximum Daily Concentration (mg/L)	Annual Average Concentration (mg/L)	SPDES Daily Limit (mg/L)
Ammonia	4,960	519	20.00
Phenols	158	0.54	0.30
Cyanide	0.21	0.04	0.01
Lead	4.9	0.14	0.20
Aluminum	183	3.18	1.80

Leachate with these pollutant concentrations is entering the environment today. Clearly, leachate pretreatment is needed to enable the leachate to meet the SPDES discharge limits.

NYCDOS commissioned a hydrogeological study of the Landfill, which showed that most of the leachate generated by the active portions of the Landfill does not flow downward towards groundwater, but rather, moves laterally into adjacent surface waters.[60] Landfill Section 6/7 is estimated to generate 310,000 gallons per day of leachate, and Section 1/9 about 590,000 gallons per day.[61] Groundwater modeling indicates that only five percent of the leachate from Section 6/7 moves vertically downward towards groundwater, and only 15 percent of the leachate from Section 1/9 does likewise.[60,61] Nonetheless, NYCDOS has found evidence that leachate has contaminated the groundwater below portions of Section 1/9, but noted that the groundwater there is already nonpotable because of salt water intrusion.[60]

NYCDOS commissioned studies to directly measure the impact of leachate migration on surrounding surface waters and on sediment-dwelling organisms (e.g., worms).[62] The study also included bioassay analyses, in which various aquatic organisms (e.g., fish) were exposed to leachate from the landfill.[62] Results of these studies showed that:[62]

- Landfill leachate is causing measurably elevated levels of ammonia and some metals in nearby surface waters – specifically in Main Creek and Richmond Creek.
- No discernable effect of landfill leachate on sediment-dwelling organisms was observed.
- Based on the bioassays, ammonia levels in the leachate can be detrimental to aquatic life.

- Section 3/4 – On the boundary between Section 3/4, and the residential community of Travis. This is in the general area southeast of the intersection of Route 440 and Victory Boulevard.

The report documenting these measurements of gas migration recommended that mitigative steps be taken[66].

As noted previously, the gas from a small portion of the Landfill is presently collected, treated, and sold to an off-site utility company. In response to the Consent Order, NYCDOS has installed gas collection and venting trenches to vent all gas migration pathways from the entire Landfill.[65] NYSDEC also operates a landfill gas monitoring system per the Consent Order to ensure methane gas concentrations do not reach explosive levels.[42] Finally, NYCDOS is presently in the process of procuring and implementing systems intended to control gas collected from the entire Landfill.[9]

Ambient Air Quality Monitoring

Continuing odor problems with the Fresh Kills Landfill have raised community concerns as to whether toxic air pollutants may also be emitted that are causing adverse health effects.[54] In response, NYCDOS and DEC are jointly funding a one-year air monitoring study to characterize air quality on and near the Landfill. As described by DEC[67], the program entails five monitors operated on the Landfill, four just off site in the neighborhoods, and two at greater distances. Pollutants monitored will include specific VOC's of concern for health (e.g., benzene, toluene), polar compounds (e.g., formaldehyde, hydrogen sulfide, acetonitrile), toxic metals, particulate matter and methane. DEC reports[68] that data from this monitoring program, along with data from other studies of environmental quality on Staten Island, will be used by the Federal Agency for Toxic Substances and Disease Registry (ATSDR) to address the health risks associated with exposure to the Landfill and other air pollutant emitters in the Staten Island region.

Air Pollutant Emissions

As will be detailed below, air pollutant emissions from the Fresh Kills Landfill have been quantified, and are shown to exceed, by a wide margin, regulatory thresholds established under the Clean Air Act (CAA) and its 1990 amendments (1990 CAAA).

- L_o, the methane generation potential (A value of 5441 ft^3 CH_4/Mg MSW was assumed to apply for MSW in place in the Fresh Kills Landfill, based on a value determined specifically from gas testing at the Fresh Kills Landfill in 1992.[72] For MSW to be landfilled after 1994, the average [default] value within US EPA's model was used; i.e., 4953 ft^3/Mg.[71,72,73])

- NMOC concentration in landfill gas (A value of 1532 ppmdv, as hexane, was assumed for MSW now in place, based on US EPA proposed guidance,[73] and 1398 ppmdv for MSW to be landfilled after 1994.[73]

- Gas collection system efficiency (US EPA has estimated 50-75 percent; 75 percent efficiency was conservatively assumed for this model application)

- Control device efficiency (a 98% control efficiency for thermal destruction of NMOC in landfill gas was assumed for the control device; e.g., flare, engine, turbine)

Secondary emissions from the control device were estimated using emission data given by the California Air Resources Board (CARB),[74] except for dioxin. Dioxin emissions were based on test data reported in the literature.[28] For on-site diesel equipment, emissions were based on US EPA emission factors,[31] except for dioxin. Dioxin emissions were estimated for on-site diesel equipment, based on tested dioxin emissions from diesel trucks in Norway, with those test data adjusted by others to reflect a lower operating load than highway trucks.[29,30] For the diesel equipment, the assumption was made that approximately 15 horse-power-hours are needed to process a ton of MSW at a landfill.

Future Landfilling Scenarios Considered.

Based on the most recent estimates by NYCDOS, the following summarizes the past and projected future quantities for MSW landfilling at the Fresh Kills Landfill,[9] beginning in 1977. Estimates are given by Landfill Section Number, and for the Landfill in total.

Landfill Closure (2015), for an intermediate date (2003), and for a year (2046) that is over 30 years beyond the assumed closure date.

The VOC emission rates reflect contributions from "uncollected" and residual emissions of landfill gas, as well as from on-site diesel equipment. NO_x and CO emissions included contributions from the on-site diesel equipment, as well as the gas control devices. Regarding the latter, emission rates are given for three different control devices – flares, engines, and turbines. NYCDOS is presently procuring and implementing gas-control systems to serve the entire Landfill. Those systems would be expected to use one or more of these types of control devices.

Referring to Table 1, clearly, the emission rates of VOC, NO_x, and CO are large for all three Landfill Cases. The emission rates are hundreds to thousands of tons per year through the assumed date of Landfill closure (2015), and are still hundreds of tons per year over 50 years from today (year 2046).

These emission rates can be put in perspective by comparison with regulatory thresholds established under the Clean Air Act (CAA) and its 1990 Amendments (CAAA). For example, under the CAA, any new emissions source with emissions of NO_x, CO (or certain other pollutants) in excess of 250 TPY, is deemed a "major stationary source," subject to Federal air-permitting requirements; i.e., a Prevention of Significant Determination (PSD) preconstruction permitting review. Presume for purposes of illustration that the Fresh Kills Landfill is a new source of emissions (in reality, it is a continuing existing source), and that it is located in an area where ambient air quality standards are not exceeded (in reality, New York City is nonattainment). With this presumption, it is clear that emissions of NO_x and of CO would each exceed the 250 TPY threshold. Further, the PSD permitting threshold is exceeded for all three Landfill Cases studied, and for all years from 1994 through at least 2015. Exceeding the threshold for only one year, in principle, is sufficient to trigger PSD permitting. Thus, if the Landfill were being newly proposed, the emission rates should trigger PSD permitting, which entails application of Best Available Control Technology (BACT), air quality impact modeling, and potentially, preconstruction air-quality monitoring.

In reality, the Fresh Kills Landfill is an existing emissions source, not a newly proposed project. But, such existing emissions sources can also be subject to PSD permitting, if a future *increase* in emissions is projected over existing baseline levels, and the *increase* exceeds the 250 TPY threshold. Table 2 shows 1993 baseline levels of VOC, NO_x,

VOC and NO_x from the Landfill appear subject to RACT requirements.

US EPA regulates Hazardous Air Pollutants (HAPs) under Title III of the 1990 CAAA. Should any new or existing emissions source emit any single HAP in excess of 10 TPY, or multiple HAPs in aggregate exceeding 25 TPY, then that emitter is a major source of HAPs. New and existing major sources of HAPs are subject to Maximum Available Control Technology (MACT) requirements. US EPA plans to promulgate MACT standards for landfills by 1997. As detailed previously, a number of regulated HAPs are known to be present in landfilled gas. In Table 3, estimated emission rates are shown for several HAPs. In addition, dioxin (PCDP/PCDF) emissions are shown, as produced by the on-site diesel equipment, and by the gas control equipment. From Table 3, the Landfill is shown to be a major source of the HAPs, xylene, toluene, and dichlorethene, since emission levels exceed the 10 TPY threshold for those individual HAPs. Such is true for all three Landfill cases studied. Also, the emission rate of all HAPs in aggregate exceeds the applicable 25 TPY threshold by a substantial margin. This demonstrates that the Fresh Kills Landfill is a major source of HAPs, and, therefore, appears to be subject to MACT requirements.

Under Title V of the 1990 CAA, a Federal Operating Permit must be obtained, and periodically renewed, by every emissions source subject to any provision of the CAA, as amended. As demonstrated above, a number of major requirements of the CAA and the 1990 CAAA are shown to apply to the Fresh Kills Landfill. Thus, the Landfill appears suspect to the requirement to obtain a Title V Operating Permit.

In summary, the Fresh Kills Landfill has been demonstrated quantitatively to be a major source of emissions of VOC, NO_x, CO, and HAPs, as defined by US EPA. As such, the Landfill appears subject to a number of key requirements of the CAA and the 1990 CAAA.

environment. Landfill emissions of VOC and NO_x exacerbate violations of the ambient standard for ozone. Emissions of Hazardous Air Pollutants (HAPs); e.g., vinyl chloride and benzene, pose a risk of cancer and other disease. Emissions of methane contribute to global warming under the greenhouse theory.

- US EPA has proposed new regulations that would, if promulgated, begin to regulate these air pollutant emissions, for the first time. Historically and at present, however, these emissions are going essentially unregulated at the Federal and state levels.

- Gas control devices (e.g., flares, engines), as well as diesel equipment (used on site to grade, compact and cover landfilled MSW) are sources of dioxin emissions at landfills.

- Large MSW landfills can have substantial emission rates of air pollutants. To illustrate this, emissions from the Fresh Kills Landfill were estimated. Projected emissions of VOC, NO_x and CO were in the range of hundreds to thousands of tons per year, as projected to year 2015 and beyond. HAPs, in aggregate, were projected to be emitted in the hundreds of tons per year. Only seven HAPs were evaluated here, of the more than 100 HAPs identified by US EPA as being present in landfill gas.

- These emission levels have extremely important regulatory implications. The emissions levels of these pollutants from the Fresh Kills Landfill (and by extension, other large landfills) exceed major-source thresholds set under the Clean Air Act (CAA), as amended. Accordingly, the Fresh Kills Landfill (and other large landfills) appear subject to a number of major requirements of the CAA, including obtaining a Federal "PSD" air permit for construction (BACT, air modeling), New Source Review in a Non-Attainment Area (LAER, offsets), imposition of MACT controls for emissions of HAPs, and obtaining a Federal Operating Permit.

- There are four contributors to air pollutant emissions, when landfills are viewed as a "stationary emissions source." Those are "uncollected" emissions (pollutants in the gas that escapes capture by the landfill gas collection system),

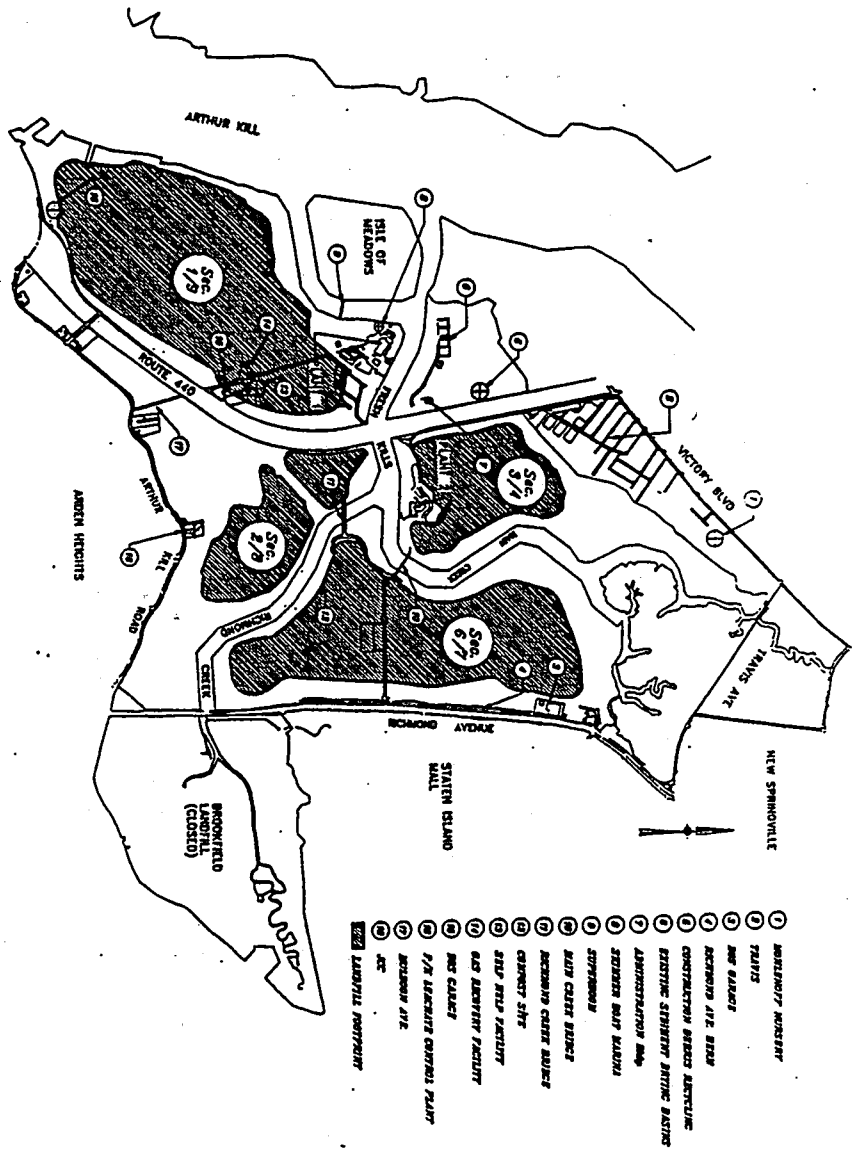

Figure 1 — Fresh Kills Landfill, New York City

Table 2

INCREMENTAL CHANGES IN ANNUAL EMISSIONS OF VOC, NO_x, AND CO, AFTER BASELINE YEAR, 1993

Landfill Case[1]	Comparisons to Baseline	Change in Annual Emissions (TPY)		
		NMOC (VOC)	NO_x[3,4]	CO[3,4]
Case 1	1993 Baseline	4,610[2]	935[3]	217[3]
	1994 vs. 1993	(-)3,511	(+)176 to 1,884	(+)358 to 2,242
	2003 vs. 1993	(-)3,309	(+)218 to 2,323	(+)441 to 2,766
	2015 vs. 1993	(-)3,121	(+)256 to 2,736	(+)519 to 3,257
Case 2	1993 Baseline	4,610	935	217
	1994 vs. 1993	(-)2,941	(+)176 to 1,884	(+)358 to 2,242
	2003 vs. 1993	(-)2,881	(+)188 to 2,007	(+)381 to 2,389
	2015 vs. 1993	(-)2,847	(+)198 to 2,113	(+)401 to 2,515
Case 3	1993 Baseline	4,000	935	217
	1994 vs. 1993	(-)3,511	(+)176 to 1,884	(+)358 to 2,242
	2003 vs. 1993	(-)3,587	(+)173 to 1,845	(+)350 to 2,196
	2015 vs. 1993	(-)3,633	(+)168 to 1,793	(+)340 to 2,134

1. See Table 1 and text for Case definitions.
2. Baseline NMOC emissions (1993) reflect the present situation of no control of collected gas (except for gas from a small portion of the Landfill). Gas control systems to serve the entire Landfill are presently in procurement and implementation by NYCDOS. Thus, NMOC emissions decreases are projected from 1994 forward.
3. Baseline emissions (1993) of NO_x and CO result from on-site diesel equipment only. The emissions increases from 1994 forward result from the added emissions from the gas control systems presently being procured and implemented.
4. Range of emission increases covers the choice of gas control devices (flare, engine, turbine). See Table 1.

EXH. 69

☑ Emissions

Comparing Air Emissions from Landfills and WTE Plants

Simplistic ideas about health effects are leading to misguided decisions about solid waste management alternatives. Risk analysis shows that WTE plants may be better than they are often perceived in comparison to landfills. This investigation suggests the importance of assessing the effects for all MSW technologies to assist decisions about integrated waste management.

By Kay H. Jones

The two alternatives that occupy the bottom positions in the Environmental Protection Agency's waste management hierarchy waste-to-energy and landfilling–rarely get truly comparable consideration. This may be due to a *perception* by the general public that the health and environmental effects of WTE are of greater consequence than for landfills.

My studies indicate that this perception is incorrect. The side-by-side health risk estimate presented here, comparing a new landfill to a new mass burn WTE plant shows that WTE plants may be a better choice than landfills for minimizing health risks and environmental effects. More important, however, the results also suggest it is time for communities and regulatory agencies to apply similar comparative assessments to each component of an MSW management plan *before* putting rigid hierarchical thinking into practice. This article (and similar investigations) should not be used to reverse, change, or finalize thinking that one technology is better than another. Instead, they should be used to "level the playing field," broadening how communities look at MSW management options, rather than to allow continuing misperceptions to control the choice of favoring one technology over another.

Kay H. Jones, PhD, is president of Zephyr Consulting, Seattle, Washington. Dr Jones has been conducting risk assessments on WTE alternatives for more than ten years, and has been a consultant and/or expert witness on more than 30 waste projects.

Current Practice Under the Hierarchy

Most recycling (and composting) projects move forward without any formal health or environmental assessments similar to those that WTE plants or landfills must go through. The lack of assessments is partly due to a perception that recycling is a no-risk strategy. However, the lack of assessments leaves a major knowledge gap that needs attention. One comparative health risk assessment I conducted, for instance, shows that MSW composting is not a zero risk methodology, and can present a *greater* health risk than WTE.[1]

In the past, health risk concerns about landfilling have centered on the potential for groundwater contamination. Better siting and facility design and engineering (with liners and leachate management) have lessened the potential problems, but haven't resolved them entirely.

Air emissions from landfills also can negatively affect health and the environment. Characterizing and quantifying these effects has begun, but further investigation is needed. Unlike the scant health and environmental data available from recycling facilities, there is a modest and growing data base on landfill air emissions. Recent state and federal regulatory activities, plus the development of dozens of landfill gas-to-energy projects, have helped to build an emissions profile. For instance, to develop the background for the New Source Performance Standards proposed in May 1991, the Environmental Protection Agency compiled emissions data for 22 landfills.[2,3,4] EPA's data from 13 of these facilities includes emissions associated with using gas control systems, such as flares, internal combustion engines (ICEs), and gas turbines. A testing program of the California Air Resources Board (CARB) also helped to extend considerably information on landfill gas composition.[5]

Health risk concerns about WTE plants have centered on air emissions, but there is also a concern about the potential for groundwater contamination from disposal of WTE ash in landfills or monofills. The relative risk of contamination due to ash filling is less than for raw waste landfills because of leachability considerations.

A few researchers have conducted limited risk assessments that compare emissions from landfills and WTE facilities.[6,7] These assessments generally analyzed the emissions from the landfill surface, but have not considered emissions associated with gas control devices. Yet, because some of these devices emit carcinogens, the risks should be calculated and considered along with other issues during the planning and siting of waste facilities.

Risk Assessment Concepts

Risk assessments focus primarily on cancer risks and typically attempt to estimate a worst-case exposure to carcinogens released by the facility. They attempt to account for all of the pathways by which each pollutant might affect a hypothetical individual residing in the location where the exposures are the highest. This person is called the Maximum Exposed Individual (MEI). Risk assessments usually state results in relative terms of chances per million of cancer risk at the MEI location caused by a lifetime of exposure (70 years) to facility emissions. This *relative* risk concept is a very important distinction from actual cancer risk, which is based on observed rates in the general population. By contrast, relative cancer risk is determined by employing models that have common input data. The results of such analyses are strictly an index of relative risks upon which risk management decisions depend.

Setting Up A Comparison

This analysis compares the principal health risks, and some of the environmental risks, associated with the air emissions from a hypothetical landfill and a WTE facility of equal capacity.

This analysis takes the conventional risk assessment approach, focussing primarily on cancer risks. A comprehensive review of *all* the expected or potential pollutants from the landfill and WTE options is beyond the scope of this article. However, the pollutants selected for review contribute the lion's share of the risk burden associated with these facilities. Dioxins are responsible for over 90 percent of the total calculated cancer burden from WTE plants. This analysis also includes other air toxics such as benzene and vinyl chloride that add to the cancer burden.

The landfill calculations include risks from emissions not captured by gas collection systems plus the emissions from the gas control systems. Landfill gas systems typically capture between 60 and 85 percent of the gas generated. EPA considers 75 percent capture achievable, so this was the basis for calculations used in this analysis.[3] Thus, risks are based on pollutants in the 25 percent uncontrolled landfill gas and the pollutants emitted from the systems controlling 75 percent of the landfill gas.

Beyond the health risks, this analysis also reviews some emissions that affect the environment, such as non-methane hydrocarbons (NMOCs), carbon dioxide, and nitrogen oxides (NOx).

Table 1 summarizes assumptions used in this comparison of two hypothetical 1,500-ton-per-day facilities. The landfill meets the proposed New Source Performance Standards (NSPS) for air emissions (i.e., 98 percent destruction of the captured hydrocarbon emissions). The WTE facility meets the existing NSPS for municipal waste combustors. The landfill operates for 30 years, which is the same as the life span normally assumed for WTE facilities. Although the depths of landfills can vary widely, the 24-foot depth used in this study is consistent with the model EPA used in their NSPS documentation.

The facilities are sited at the same geographical location, so that air emissions dispersion could be modeled using the same meteorological data. I assumed that flat terrain exists, although terrain effects can be and are assessed in actual cases on a site specific basis.

Table 1. Assumptions in Risk Assessment Comparison.

Facility	Landfill	WTE Plant
Size	1500 TPD	1500 TPD
Operational life	30 years	30 years

Gas Collection Efficiency	75%	—
Stack height	—	67 meters*
Pollution Control	None	Spray dryer/ Fabric filter

* Includes plume rise. — indicates not applicable.

Data Sources

Emissions data for the WTE case were obtained from available compliance test reports and other literature sources. The WTE dioxins emissions factor used was 0.1 nanograms/cubic meter (ng/m³) Toxic Equivalents, which is slightly above the geometric mean of the available data on 12 state of the art WTE facilities in the U.S.[9] Emissions regulations and facility permit limits in the U.S. are typically based on total dioxins and furans. However, in doing risk assessments, the risks from these emissions are calculated as Toxic Equivalents of 2,3,7,8 dibenzo-p-dioxins using the International CCMS Methodology.

To quantify dioxins emissions from landfill gas control devices for this investigation, I used measurements reported in a study of emissions from flares and ICEs in Germany.[9] The German data was used since quantitative dioxin emissions data from controlled landfills in the U.S. is nonexistent. CARB used low resolution mass spectrometry in analyzing samples during three testing campaigns previously cited. They detected furans, but could not quantify dioxins. Since dioxins and furans are always collectively emitted from combustion sources; and since dioxins and furans have been identified and quantified in mobile ICEs; there is sufficient support to believe they are present in the landfill gas combustion system exhaust gases.[10,11,12]

The landfill air emissions factors for pollutants besides dioxins were taken from EPA and CARB reports. The physical parameters (such as stack height, gas flow, etc.) for the gas destruction devices were taken from three CARB emissions test reports.[13,14,15]

Landfill gas is about half methane and half carbon dioxide with minimal amounts of other gases, including air toxics of concern such as benzene and vinyl chloride. Table calculations were based on a methane generation potential of 140 cubic meters per megagram (m^3/Mg) of MSW and a methane generation rate constant of 0.031. These values represent the average for the range of observed data reported by EPA.[4] There is some question about the representativeness of the EPA data because most the data is from landfills located in

Compost Happens.

Faster.

Willibald shreds residentially collected yard waste at rates over 200 cubic yards per hour. That is twice as fast as the larger rotor or demolition grinders!

How do we do it? Willibald was designed for composting – a continuous feed system, a non-plugging shredding mechanism, and long-lasting hammers maximize throughput with minimal downtime.

And minimal cost. Our non-stop, high output capacity means your cost per ground ton is typically 1/3 that of the competitors'.

Highest output, lowest cost, least downtime. Why not call our factory for more information and the name of your nearest Willibald representative today!

drier California climates. Landfills located in wetter climates would likely decompose faster and hence generate higher peak year and average gas flows. This in turn would increase the estimated off-site exposures to air toxics.

One caveat must be considered when using historical landfill gas toxic air pollutant composition data. It is possible that future landfills will have "cleaner" gas profiles because more communities are setting up programs to collect and manage some toxic constituents in MSW. The same caution applies to the use of current WTE emissions factors. In particular, trace metals emissions are clearly dependent upon waste stream composition.

To make an equitable comparison of potential exposures from landfill and WTE air emissions a common exposure period must be established. Thirty years of facility operation and a 70-year life is assumed. The hypothetical lifetime risks from WTE accumulate in the first 30 years, but for the risk assessment are calculated as though they would occur spread throughout 70 years. After the WTE plant ceases 30 years of operation, the only remaining risks are from those pathways that involve contact by humans or animals with the soil that was contaminated during plant's operating life. This analysis ignores this residual risk, which would add only a few percent of additional risk to the operating period risk. The landfill is projected to generate landfill gas for more than 110 years. For this analysis, the risk burden from the landfill is based on the average of the first 70 years of emissions. The remaining 40 years of risk

Table 2: Dilution Factors and MEI Locations for the WTE and Landfill Air Emissions

Disposal Options	Effective Stack Height (meters)[1]	Dilution Factor (ug/m³gps)
WTE Stack	87	0.0127
Landfill surface	0[2]	7.5
Landfill flare	40	0.215
Landfill ICE	13	4.67
Landfill turbine	58	0.164

[2]Effect of possible gas temperature related buoyancy was assumed to be negligible

gps = grams per second

Table 3: Comparing Cancer Risks from Dioxin Emissions, WTE vs. Landfills

Disposal Alternative	Emissions Rate*	Cancer Risk (chances/million) Inhalation	Multi pathway**
WTE	7.57×10^{-9}	0.0019	0.07
Landfill flare	0.73×10^{-6}	0.0070	0.25
Landfill ICE	0.34×10^{-6}	0.072	2.53
Turbine	ND	—	—

*Emission rate is grams per second, in Toxic Equivalents; ND = Not detected
**The table's multipathway total is calculated by multiplying the inhalation risks by 35. This ratio is based on estimates used in a risk assessment for a WTE plant sited in rural Montgomery County, Maryland. The risk assessment considered the consumption of locally grown produce and meat and dairy products.

burden is hypothetically passed on to the next generation.

The pathways of exposure include direct exposure through stack emissions and indirect exposure through contaminated soils and foodstuffs. For dioxins, the principal human exposure is through consumption of beef and dairy products from locally raised animals. These animals accumulate dioxins primarily by eating fodder on which dioxins have deposited from the air. According to a risk assessment conducted for the Montgomery County, Maryland, WTE facility, the distribution of estimated dioxin/furan risk was: beef and dairy intake, 87.1 percent; vegetable consumption, 5.1 percent; dust ingestion, 4.6 percent; inhalation, 2.8 percent; fish intake and other routes, less than 1 percent.[16]

Table 4: Cancer Risks (chances per million) from Inhalation of Benzene and Vinyl Chloride Emissions from WTE and Landfill Facilities

Disposal Option	Benzene	Vinyl Chloride
WTE	0.00023	ND*
Landfill surface	4.8	13.6
Landfill flare	0.0022	0.00
Landfill ICE	3.4	0.51

*Not detected in emissions test

Dispersion Modeling of Emissions

The exposure for the Maximum Exposed Individual (discussed in accompany box) is calculated by first quantifying the annual average emissions from a facility, then determining by which routes or pathways an individual might be exposed to the pollutants. The MEI exposure is estimated based on how the emissions are dispersed from the stack. Factors such as stack height, wind direction, wind speed, and vertical mixing are considered in this dispersion modeling. Rainfall and emissions particle sizing are added considerations when estimating the level of soil and vegetation contamination. Due to its taller stack, for instance, the WTE plant has an MEI location much farther from the source (as illustrated in Figure 1), and the dilution factor is much greater.

Our analysis used an EPA dispersion model (ISCST2) and five years of meteorological data from the Seattle Tacoma International Airport (SEATAC).[17] The representativeness of the SEATAC results were tested by also modeling data from Hanford in eastern Washington. Hanford is in an entirely different geographical region with different meteorological conditions. The additional modeling yielded similar results and dilution factors, suggesting that the *relative* risk estimates are not heavily dependent on geographical location.

Table 2 shows the dilution factors and distances from the facility to the MEI location for the five scenarios. Figure 1 plots the dilution factors versus distance from the various sources. These data suggest the following:

—For the same emission rate of any pollutant, the risk is the highest for the ICE gas control option regardless of the distance from disposal site.

—Emissions which emanate from the landfill surface have much higher relative effects close to the landfill. These fugitive emissions (not captured by the control system) add effects to those for gas control devices at MEI locations.

—The number of persons at risk is much higher for all of the landfill fugitive and gas control cases than for the WTE plant, if the emissions rate for any given pollutant is the same. The figure shows, for example, that the WTE plant emissions affect people residing between 3,000 and 7,000 meters away from the facility, while the ICE affects people beginning less than 100 meters away. This assumes a uniform population density surrounding the two disposal options. Of course, uniform population density may not be the most likely scenario. Many landfills are sited in remote rural areas, while many WTE plants are sited in urban areas. And such siting practices will influence the comparative risks. For example, if a WTE plant is sited in an urban area, the total dioxin related risk drops dramatically because the beef and dairy pathway would not exist.

Table 5: Relative Cancer Risks from MSW Disposal Options and Other Activities

Chances per Million	Activity
5,000	Average household exposure to radon[1]
4,640	Pesticide residue on fresh foods[2]
720	Consumption of 1/2 pound of fish per week from Lake Ontario[3]
250	Peanut butter consumption by children, due to aflatoxin contamination[4]
180	Acceptable benzene levels[5]
20	Average diagnostic medical X-ray[6]
18	1500 TPD landfill fugitive benzene and vinyl chloride emissions inhalation only
11	MSW compost dioxin/furan exposure
10	Acceptable Ambient Level of inhalation exposure only, State of Maryland[7]
4	Frequent flyer radiation exposure 20,000 miles/year[8]
2.4	Drinking and showering with chlorinated water[9]
0.07	WTE 1500 TPD dioxin/furan emissions, all pathways

Health Impacts

The estimated total dioxin/furan cancer risks for the landfill and WTE scenarios

are shown in Table 3. The encouraging result is that the total cancer risk from dioxins for all of the management scenarios is very low—and below EPA's acceptable Superfund multipathway guidance of one chance in 10,000. Even so, the two landfill gas control options pose far more risk than WTE emissions. The flare poses 3.6 times the WTE risk and the ICE poses 36 times the WTE risk.

HAPS Results

The Clean Air Act Amendments of 1990 listed 189 pollutants as Hazardous Air Pollutants (HAPs), and specified both an emissions threshold of 10 tons per year for any one HAP and a combined threshold of 25 tons per year for two or more of the listed HAPs. If these thresholds are exceeded, Maximum Available Control Technology (MACT) must be employed. This new emphasis on such a range of pollutants has created a need to identify emissions levels and possibly trigger a requirement to control HAP emissions at new and existing facilities.

Over 30 of the listed HAPs have been identified in uncontrolled landfill gas. Estimates using the EPA data base indicate that an uncontrolled 1,500 TPD landfill would emit a total of more than 60 tons per year of just seven of the HAPs with the highest average uncontrolled gas concentrations. The estimates are for the peak year of gas generation in the landfill. By comparison, a 1,500-TPD waste-to-energy facility is estimated to emit only 15 of the listed HAPs and a total of 2.4 tons of HAPs annually. The WTE plant would emit only trace amounts of dioxins and PCBs, two other organics (benzene, and aldehydes), and less than 1.5 tons per year total of eleven of the listed metals. None of the HAP pollutant emissions from WTE plants approach the guideline control levels.

Two HAPs with assigned human cancer potency factors and the highest emission rates, benzene and vinyl chloride, were assessed in this study. Table 4 shows the comparative cancer risks from inhalation for these pollutants. (There were no emissions factors available for turbine landfill gas combustion.) Similar to dioxin cancer risks, the relative risks associated with the landfill option are far greater—from 10 times to 20,000 times higher—than for the WTE option. The total cancer risk for the uncontrolled landfill benzene and vinyl chloride emissions exceeds 10 chances per million, the acceptable threshold for

Dry Injection Is Proven

Our All Dry Scrubbing System at the Quebec City 1000-tpd Municipal Waste Combustor is a perfect example of the performance of the Procedair Dry Injection System.

Mercury emission levels at this MWC are reduced by more than 95%. Official tests by Quebec's Ministry of Environment show emission levels consistently below 10 mg/Nm³.

When coupled with the Procedair All Dry Scrubbing System, with its dry venturi reactor and built-in recirculation, activated carbon consumption is further minimized.

Procedair Has What It Takes

Procedair Industries handles air pollution control projects of any size. We are the North American branch of a global network of companies specializing in air pollution control. Our technical knowledge and financial resources are backed by over 60 years of experience and proven designs.

For your new plant or retrofit, trust Procedair for advanced, efficient designs, on-time installation and competitive pricing. Call today. We'll give you all the dry details—and the exciting benefits—of the Procedair Dry Injection System.

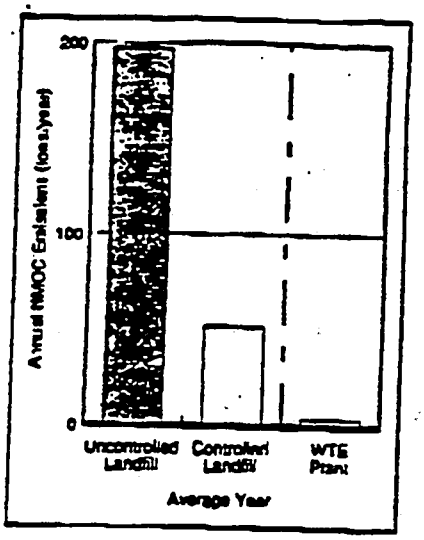

Figure 2: Comparison of Annual NMOC Emissions (tons per year) from a 1,500-TPD landfill and a 1,500-TPD waste-to-energy facility

inhalation risk in many states. Under existing California legislation, for example, such an exceedance requires public reporting. And in the state of Washington, a detailed risk/benefit analysis is required if the risk exceeds 10 chances per 100,000.

The results of this analysis do not suggest that the risks associated with the alternatives discussed are necessarily unacceptable. That is, while the risks for landfill options are higher than WTE plants, the risks for all of the options are quite low and may still compare favorably to everyday unrecognized involuntary risks (see Table 5).

Environmental Impacts

A proper comparison of air emissions from landfills and WTE facilities must consider more than just risk from carcinogenic pollutants. Non-methane hydrocarbon (NMOC) emissions, for instance, are a major public concern because they can be significant contributors to ozone loading in non-attainment areas. Figure 2 shows the estimated annual NMOC emissions from controlled and uncontrolled 1,500-TPD landfills in comparison to average annual emissions for the same size WTE plant.

Table 6 shows the comparative CO, NMOC, NOx and dioxin/furan emissions (on a common Btu basis) for the flare, ICE, and turbine gas control technologies versus the most likely emissions from a new WTE plant. In all cases, except for the flare and turbine NOx emissions factors, the WTE plant emissions are the lowest. The table also indicates that WTE facilities have regulatory limits (e.g., dioxin/furan emissions in the last column) that other facilities are not required to meet.

Based on these figures, it appears that a 1,500-TPD landfill proposed in an ozone non-attainment area should have to undergo Nonattainment Area New Source Review (NANSR). Landfills currently do not undergo such reviews. There is no EPA requirement under the Clean Air Act in this regard. NANSRs require offsets and the application of Lowest Achievable Emissions Rate (LAER) control technology. Yet, conducting NANSRs for landfills would also raise questions that have not yet been addressed, including: What *is* LAER for the various landfill pollutant control system emissions?

Another complication is that, as discussed earlier, controlled landfills will capture only about 75 percent of the generated gas. Excluding the 25 percent fugitive emissions is inconsistent with other existing regulatory approaches under the Clean Air Act. The philosophy underlying the Act is the maximum control of emissions. Yet landfills—even under the proposed New Source Performance Standards—would not be required to meet the same tests which have been applied to WTE plants and other facilities under the same provisions. Petroleum, petrochemical, and treatment and storage operations (TSO's) must use Best Available Control Technology to manage all emissions.

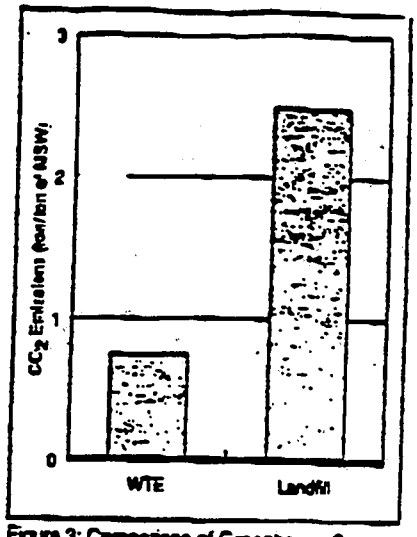

Figure 3: Comparison of Greenhouse Gas Emissions (in CO_2 Equivalents) from a 1,500-TPD landfill and a 1,500-TPD waste-to-energy facility

Greenhouse Gases

Proponents of the Greenhouse gas theory believe that man-made sources of several gases (among them CO_2 and methane) are causing global warming because they are building up in the earth's atmosphere. This buildup traps the infrared radiation being reflected from the earth's surface. If one prescribes to this theory (which the author does not), then these pollutants should also be considered in an equitable regulatory review process.

Landfills emit significantly higher amounts of greenhouse gases than comparably sized WTE facilities. Figure 3 shows this comparison in CO_2 emissions equivalents. Different gases have different impacts per ton of emissions; CO_2 emissions are used as a benchmark for estimating relative contributions. Methane is considered to be 25 times more potent than CO_2 in trapping the infrared radiation than CO_2.[18]

Other Issues

Another risk that can be compared for the various facilities is that associated with waste transportation. The accident-related risks are likely to be higher for the landfill option either because of increased trucking distances or the use of additional transportation modes such as rail haul. There may also be greater

Table 6: Emissions of CO, NOx, NMOCs and Dioxins from WTE Plants and Landfill Gas Control Devices

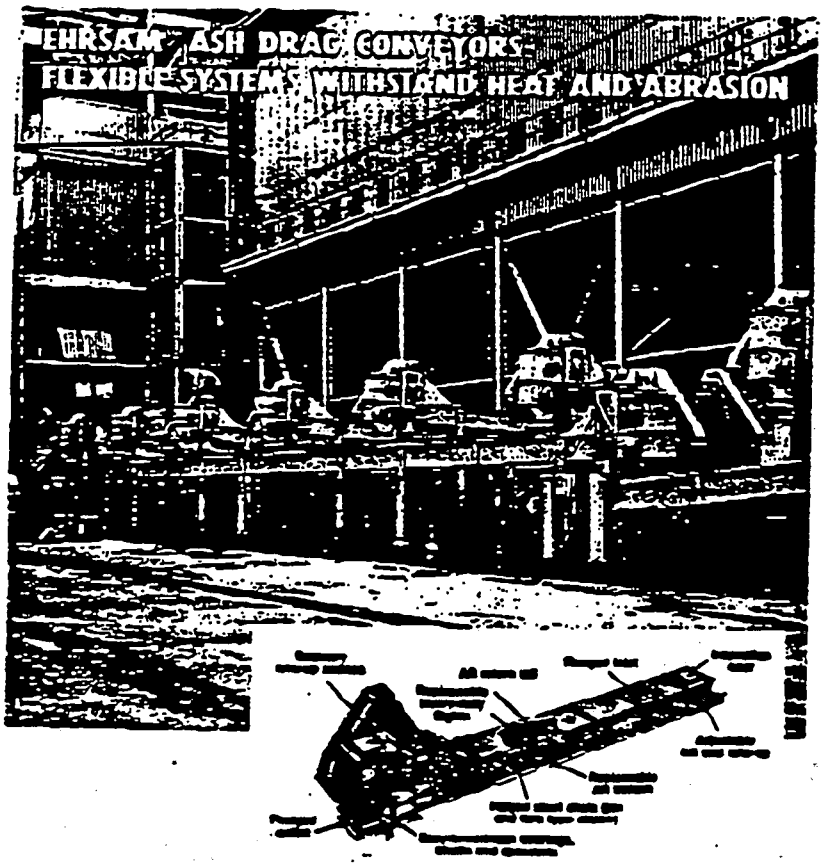
Facilities	Emission Factors (grams per 1000 Btu)			
	CO	NMOC	NOx	Dioxins
WTE	0.01	0.5×10^{-3}	0.11	1.3×10^{-6} [b]
Landfill flare	0.04	5.1×10^{-6}	0.02	5.2×10^{-6}
Landfill ICE	0.23	5.1×10^{-3}	0.19	1.6×10^{-6}
Landfill turbine	0.04	5.1×10^{-3}	0.10	ND

[a] For the landfill options, the emissions reported are from the landfill gas control devices only; these figures exclude fugitive emissions from the landfill surface.
[b] Equivalent to 3.0 ng/m³ total PCDD/PCDF.

emissions of ozone-forming pollutants, such as NMOCs and NOx. (Of course, there would be no transportation difference if you assume the same location for the landfill and the WTE plant). Landfill sites are moving further and further from the waste generation centers. For example, the City of Seattle chose to rail haul their waste more than 200 miles rather than build a WTE facility in the city. Although a health risk assessment found the WTE option to be acceptable, no comparative accident risk assessment was performed on the two disposal options.

So far, this analysis has sought to characterize the disposal options based on minimizing their negative effects. Yet, three of the discussed disposal options recover energy, a net benefit which should be considered in the selection process. A WTE facility recovers between two and three times more the energy per ton of MSW disposed of than by landfill gas recovery. This is because, in a landfill, a large portion of the solid fuel is not converted to gas, and hence cannot be recovered as energy. Over a period of 20 to 30 years, 20 to 60 percent of the refuse in a landfill will be converted to gas by anaerobic digestion.[9]

Conclusion



To date, WTE has been given microscopic scrutiny from a risk perspective by regulatory agencies. No similar scrutiny has been given to the other options in the disposal hierarchy. The scrutiny applied to WTE has suggested to the public that WTE facilities pose unacceptable risks while other options pose no calculable risk. In fact, as shown in this investigation, for some options, the reverse may be true.

When a new landfill and WTE facility of equal capacity are compared from a risk perspective, under specified assumptions, the landfill appears to pose greater health and environmental risks. An important inclusion in this investigation was calculating risks from landfill gas control devices. To date, regulators have focussed on fugitive landfill emissions, but have not considered emissions from landfill gas control devices.

Despite the comparative nature of this analysis, this paper is not intended to lead to a conclusion to select one technology over another. In fact, the risks associated with each of the alternatives are not necessarily unacceptable compared to everyday involuntary risks. And, ultimately, multiple technologies are needed in an integrated waste system. Indeed, the important judgment to make from this kind of analysis is that it is time for communities and regulatory agencies to apply the same level of health and environmental review to all components of proposed MSW management plans. Communities need a level base of information to be able to convince the public and regulatory agencies about the merits of their MSW management approaches. ■

ACUTE RESPIRATORY EFFECTS OF PARTICULATE AIR POLLUTION

D. W. Dockery and C. A. Pope III
Environmental Epidemiology Program, Harvard School of Public Health, Boston, Massachusetts 02115-6096

KEY WORDS: particulate air pollution, adverse health effects

INTRODUCTION

In the 1930s, 40s, and 50s, several episodes of extreme air pollution focused attention on the potential for adverse health effects of air pollution. These included an episode in the Meuse Valley, Belgium, in December 1930 (15), an episode in Donora, Pennsylvania in 1948 (36), and several episodes in London, England (23, 44). The sudden large increases in sickness and death that accompanied such episodes demonstrated that air pollution can adversely affect human health. The increased mortality associated with such episodes provided the first quantitative measure of the adverse effects of air pollution.

By the 1970s, a link had been well established between respiratory disease and particulate and/or sulfur-oxide air pollution, but still there remained disagreement as to the level of pollution that would significantly affect human health. In reviewing research published between 1968 and 1977, Holland and several other prominent British scientists (19) concluded that particulate and related air pollution at high levels pose hazards to human health, but that health effects of particulate pollution at lower concentrations could not be "disentangled" from health effects of other factors. Shy (45) responded by asserting that the review by Holland et al systematically discounted evidence of pollution-related health effects at contemporary pollution levels. Shy, and other reviewers (1, 12, 45, 54), contended that the cumulative weight of evidence provided sound reasons to believe that

0163-7525/94/0510-0107$05.00

human health may be adversely affected by particulate pollution, even at relatively low concentrations.

Epidemiologic studies since the 1970s have provided more quantification of the health effects associated with particulate pollution at levels common in contemporary urban areas of the developed world. Recent epidemiological research has been based on more specific definitions and more precise measures both of pollution exposures and health endpoints. Advances in biostatistical and econometric analytic techniques for time-series data have expanded the opportunities to evaluate the acute health effects of particulate pollution and have increased the analytical rigor of these studies. In particular, advances in autoregressive Poisson and logistic regression analysis have permitted the evaluation of pollution associations in panels of patients or other small populations, which would not have been possible in the early 1970s. Most notable has been a series of studies showing that daily mortality is associated with particulate pollution at concentrations much lower than those experienced in the extreme episodes of the first half of this century.

Bates (3) has recently pointed out that the observation of increased mortality associated with air pollution exposures implies that measures of morbidity also must necessarily be increased—for example, hospital admissions, hospital emergency room visits, and outpatient or doctor's visits. Among potentially responsive subjects such as asthma patients, we expect to observe increased symptoms, lower lung function, increased medication use, and, ultimately, higher use of hospital services. A similar cascade of associations also may be detected among less sensitive individuals, i.e. among members of the general population. Bates (3) has described this as *coherence* of effects, i.e. the adverse effects of air pollution should be observable across a range of related health outcomes. Adverse effects of air pollution also should be reproducibly observed by different investigators in different settings, i.e. there should be *consistency* of effects across independent analytic studies.

This review presents a comparison of such recent studies of the acute effects of particulate air pollution and shows evidence for increased mortality and morbidity associated with particulate pollution, even at moderate concentrations. We evaluate both the coherency and consistency of recent epidemiologic data regarding adverse health effects of particulate air pollution. Our purpose is to stimulate a new look at these studies rather than to provide a comprehensive, detailed, or complete review.

SOURCES AND EXPOSURES

Particulate air pollution refers to an air-suspended mixture of solid and liquid particles that vary in size, composition, origin, and effects. The term

'aerosols' refers to a stable mixture of suspended particles and gases and therefore implies smaller-sized particles. Particulate air pollution is formed by condensation of gases or vapors, or by direct generation through mechanical processes. The different processes of formation lead to characteristic differences in size and composition of particles.

Particle Size and Chemical Characteristics

Particle size is expressed in terms of its aerodynamic diameter, defined as the diameter of a unit-density sphere that has the same settling velocity as the particle in question. The size distribution of suspended particles in the atmosphere is bimodal. Large particles (sometimes called "the coarse mode") are 2.5 to 30 μm aerodynamic diameter and most often have a basic pH. These large particles are derived from uncontrolled combustion and mechanical breakup of soil and other crustal materials. Biological particles such as pollens and spores are also found in this large-particle range. Smaller particles ("the fine mode") are < 2.5 μm aerodynamic diameter and are often acidic. These fine particles include soot and acid-condensates derived from vehicle emissions, manufacturing, power generation, and agricultural burning. Sulfate and nitrate aerosols generally make up the largest fraction of small particles by mass.

Deposition, Clearance, and Toxicity

Particle size is the most important characteristic influencing deposition in the respiratory system (2). Models of inhaled particle deposition relate aerodynamic particle diameter to the site of deposition. Most inhaled particles of greater than 5μm aerodynamic diameter deposit in the upper airways or larger lower airways. Particles smaller than 5μm aerodynamic diameter are more likely to deposit in the smaller airways, e.g. the bronchioles and the alveoli.

Particle clearance is achieved by several mechanisms. Particles deposited in the trachea and bronchioles rise on the mucociliary ladder to be expelled by coughing or to be swallowed. Particles deposited beyond the terminal bronchioles are cleared largely by lung macrophages that, in turn, transport the ingested particles onto the mucociliary ladder or into the lymphatic system. A small fraction of these distally deposited particles migrate through alveolar tissue directly into the lymphatic circulation.

Biologic effects of a particle are determined by the physical and chemical nature of the particle itself (particularly its solubility), the physics of deposition and distribution in the respiratory tract, and the physiologic events that occur in response to the particle's presence. Controlled human studies have focused on airway effects of single agents or simple mixtures. Toxicological studies have generally focused on chronic effects and single agents

(e.g. silica, asbestos) (55), and on the effects on sites of deposition or distribution (airways, alveoli).

Measures of in vitro macrophage cytotoxicity demonstrate the high toxicity of certain urban particle complexes relative to the classic toxic dusts, e.g. silica and asbestos. Toxicity of urban particles and diesel particulate emissions depend in part on the type of metal compounds they contain, as well as their combustion-derived organic content (16).

REVIEW METHODS

Definition of Exposure

In 1987, the US Environmental Protection Agency redefined the National Ambient Air Quality Standard (NAAQS) for particles based on particulate matter smaller than 10μm aerodynamic diameter (PM_{10}) (13). This 10μm-size cutoff focused monitoring and regulatory efforts on particles of a size that would be deposited in, and damaging to, the lower airways and the gas-exchanging portions of the lung. Recent epidemiologic studies have used PM_{10} measurements as the basis of exposure estimation. Earlier studies, however, used a variety of measures of particle concentration to define exposure. These alternative measures are discussed below to compare results with PM_{10}-based measures.

The EPA's initial standard reference measure for particles was Total Suspended Particulates (TSP), measured by high-volume samplers. This sampling method has an ill-defined upper size limit between 25μm and 45μm that is dependent on wind speed and direction (22). In addition, TSP measurements are subject to artifactual conversion of SO_2 to sulfate on the filters or to volatilization of nitrate aerosols from sampler filters. Many epidemiologic studies of air pollution in the 1960s and 1970s in the United States used TSP measurements as the indicator of particle exposures. The EPA (26) determined that the PM_{10}-to-TSP ratio was generally between 50% and 60% for US sampling sites.

In the late 1970s and early 1980s, the EPA established a network of particulate matter samplers with an upper-size cutoff of 15μm aerodynamic diameter (PM_{15}) to measure "inhalable particulates." This cutoff was recommended to define the fraction of particles that would deposit primarily in the conducting airways and the gas-exchange areas of the respiratory system during mouth breathing (24). Only very limited data are available comparing the PM_{15} to PM_{10} concentrations, but concentrations measured by these two methods appear to be similar.

In addition to the total inhalable particle concentration, particles smaller than 2.5μm aerodynamic diameter ($PM_{2.5}$) were measured based on consideration of their characteristic chemical composition and the predominant

penetration into the gas-exchange regions of the respiratory tract (24). Spengler & Thurston (47) have presented data for $PM_{2.5}$ and PM_{10} from six US cities. The mean $PM_{2.5}$-to-mean PM_{10} ratio was approximately 60%.

In most parts of the United States, fine particle ($PM_{2.5}$) concentrations are highly correlated with sulfate (SO_4) concentrations. For example, in the Six Cities Study (47), city-specific correlations were all greater than 0.70, and in four cities, greater than 0.84. In these data, the mean ratio of SO_4 to PM_{10} was approximately 25%.

Studies from Great Britain and other European countries have often used a pseudomeasure of particle mass called British Smoke (BS). This is a measure of the darkness of particles collected on a filter and determined by reflectance. Mass concentration is estimated based on the reflectance of a standard particle mass. Calibration of reflectance depends on the specific chemical composition of the particles (22). The upper size limit of the sampler is nominally 4.5μm aerodynamic diameter, although the penetration of particles through the sampler inlet does not define a sharp size cut-point (22). Generally, particles in the fine mode tend to be dark while those in the coarse mode tend to be lighter in color (11). British Smoke, therefore, is thought of as a measure of fine particle mass concentrations. The EPA (26) concluded that British Smoke was equal to PM_{10} as a lower bound and equal to TSP as an upper bound.

In the United States, a similar method was used in which particles were deposited on a filter tape and the concentration was estimated by light transmission through the sample, measured in Coefficient of Haze (CoH) units. A comparison of CoH and PM_{10} measurements in Santa Clara County, California, indicated that the CoH-to-PM_{10} ratio equals 55% (14).

Thus for this discussion we will use the following guidelines for estimating PM_{10} exposures in epidemiologic studies where other measures of particle concentration were reported:

$$PM_{10} \approx PM_{15} \qquad PM_{10} \approx PM_{2.5}/0.60$$

$$PM_{10} \approx TSP * 0.55 \qquad PM_{10} \approx BS$$

$$PM_{10} \approx CoH/0.55 \qquad PM_{10} \approx SO_4 * 4$$

Criteria of Study Selection

In this review, we have included studies that provide the following information (a) exposure to particulates reported as PM_{10} concentrations or a

measure that allowed conversion to PM_{10}; (*b*) health effects measured as change in mortality or indicators of respiratory disease with time scales of days up to weeks or months; and (*c*) reported measures of association and their variance, which would allow calculation of the relative increase in effect compared to particle exposures and the confidence that can be ascribed to the effect estimate.

We have separated epidemiologic studies by comparable health endpoints (for example, mortality or exacerbation of asthma). Within each of these health endpoints, we have expressed reported results as the estimated relative percent change in the health measure associated with a 10 $\mu g/m^3$ increase in daily mean PM_{10} concentrations. For many recent studies that used logistic or Poisson regression and PM_{10}, this is a simple calculation based on reported regression coefficients and their standard errors. Many earlier studies, in which particle concentrations were not measured as PM_{10}, required converting from the reported measure of particle concentrations to PM_{10} concentrations, conversions based on relationships described above.

In some studies, particularly those with continuous health endpoints such as pulmonary function, associations are reported as a linear rather than a proportional (or logarithmic) change associated with particulate pollution. For these studies, we re-estimated the effect as percent change from the mean response associated with 10 $\mu g/m^3$ increase in PM_{10} above the mean exposure. This is a reasonable assumption for estimates close to the mean but will break down far from the mean.

For a few studies, particle concentrations had been transformed before including them in the analysis, e.g. effects reported as a function of the logarithm of the particle mass concentrations. For these studies, we estimated the effect of a 10 $\mu g/m^3$ increase in PM_{10} above the mean exposure. Again, this is appropriate close to the mean but should not be extrapolated to concentrations far from the mean.

Ninety-five percent confidence intervals were calculated for each exposure estimate. In most cases, reports included standard errors of the estimates or confidence intervals. In a few early studies, however, only p-values were given. In these studies we estimated the standard error, assuming a normal distribution. When p-values were reported as less than some arbitrary cut-off (e.g. $p<0.05$), the standard errors were calculated, based on the upper limit of the cut-off probability (e.g. $z = 1.96$ for $p<0.05$).

To provide a combined estimate of the effect of 10 $\mu g/m^3$ increase in PM_{10} concentration for each health endpoint, a weighted average effect estimate was calculated where the study-specific effect was weighted by its inverse variance (one over the standard error squared).

HEALTH EFFECT STUDIES

Mortality

In the past few years, a series of papers has been published describing the association between daily mortality and suspended particulate concentrations in various communities across the United States. In 1990, an association between particle concentrations and daily mortality was reported for residents of Santa Clara County, California, for the period 1980–1986 (14). Associations were observed at relatively low concentrations of particles and sulfur dioxide.

This report was followed by analyses of similar data for Steubenville, Ohio (40) and for Philadelphia, Pennsylvania, (39). Both analyses suggested increased daily mortality associated with increased particle concentrations, even after adjusting for sulfur dioxide exposures. A quantitatively similar association was reported for Utah Valley, Utah, for the period 1985–89 (33). This study was notable because these associations with particle exposures are observed in the absence of substantial sulfur dioxide or ozone pollution. In analysis of data from St. Louis, Missouri, and Kingston, Tennessee (9), daily mortality was associated with several measures of particle exposures, but not with aerosol acidity, sulfur dioxide, ozone, or nitrogen dioxide concentrations.

In large communities (with a population of several million), the mean number of deaths/day is far enough from zero that the distribution is reasonably symmetric and Gaussian statistics can be applied. In most communities, however, the mean number of deaths/day is small and the distribution is skewed towards higher values. In both cases, because daily death counts can be modeled as following a Poisson process, regression analysis using the Poisson rather than the Gaussian distribution is appropriate. Associations are typically fitted to the logarithm (ln) of the number of deaths/day, that is, on a proportional rather than a linear scale. Specifically, the Poisson regression estimates the (ln) relative risk of mortality associated with a given exposure, which can be re-expressed as a percent increase in risk. All of the recent analyses of daily mortality and air pollution have used Poisson regression methods.

Use of the same endpoint (nonaccidental daily mortality), particulate exposure measures, which can be converted into a common metric (PM_{10}), and common analytic methods (Poisson regression) make it possible to tabulate approximately comparable effect estimates: the percent increase in daily mortality for each 10 $\mu g/m^3$ increase in PM_{10} concentrations (see Table 1)

Birmingham, AL 1985-88	PM_{10} (3-Day mean)	48	1.6% (0.5%, 3.7%)	38
Combined			1.4%	

There is good consistency in the estimated effect of PM_{10} across these studies. Effect estimates range between 0.7% and 1.6% increase in daily mortality for each 10 $\mu g/m^3$ increase in PM_{10} concentration with a weighted mean of 1.0%. Ostro (26a) has recently estimated a similar combined effect (0.96% per 10μ/m^3 PM_{10}) in a review of time-series and cross-sectional mortality studies.

Four of the daily mortality studies (14, 33, 38, 39) also provided a breakdown of mortality by broad cause-of-death categories. Cardiovascular deaths, which were about 45% of all deaths in these three studies, had effect estimates between 0.8% and 1.8% (weighted mean, 1.4%) increase for each 10$\mu g/m^3$ PM_{10}. Respiratory deaths, which were 2% to 8% of the total, had effect estimates between 1.5% and 3.7% (weighted mean, 3.5%) increase for each 10 $\mu g/m^3$ PM_{10}. In all four studies, no associations were found with cancer mortality or with other causes.

Epidemiologic studies suffer from the weakness that observed associations with a specific exposure may result from an unmeasured association with an unknown or uncontrolled factor correlated with *both* exposure and disease, i.e. from a confounder. These time-series studies have the advantage that many major causes of increased mortality (such as smoking, hypertension, or even age) cannot confound the observed associations with particulate air pollution because these factors do not vary with daily pollution exposures. This is not to say that response may not differ by these factors. Indeed, the mortality effects of particulate air pollution are most strongly seen in the elderly in all those studies in which age is considered as an effect modifier.

Other factors such as weather conditions, which can vary with daily pollution exposures, are potential confounders in these analyses. All of the recent studies have attempted to control for weather factors (such as temperature) in the analysis. Residual confounding due to inadequate modeling or an unmeasured weather factor is removed by modeling the covariance of the residuals as autoregressive in these analyses. Similar associations are observed in areas with high winter particulate concentrations, characterized by trapping of direct industrial emissions—Utah Valley (33) and Steubenville (40)—and in areas of high summer particulate concentrations characterized by photochemical production of secondary particles such as sulfates and nitrates– Philadelphia (39) and Birmingham (38). The consistency of the effect estimate across different communities—in warm versus cold climates, in dry versus moist climates—suggests that climatic factors are in fact not important confounders

If we accept the association between daily mortality and particulate air pollution shown in these studies, the possibility still remains that the true association is with some other pollutant correlated with PM_{10} or with a

specific component of the mixture of particles that makes up PM_{10}. The study of St. Louis and Kingston (9) considered a variety of pollutants and found the strongest associations with PM_{15} concentrations. Several studies (9, 39) evaluated sulfur dioxide as a possible confounder; no such confounding was shown. More importantly, associations between daily mortality and particulate air pollution in communities with low sulfur dioxide concentrations—Santa Clara (14) and Utah Valley (33)—were comparable to associations in communities with high sulfur dioxide concentrations—Steubenville (40). Kinney & Özkaynak (20) reported associations between daily mortality and ozone in Los Angeles. They emphasize the association with ozone, but strong associations were also observed with KM, a measure of light scattering by particles similar to Coefficient of Haze. The consistency of results across communities suggests an important if not dominant role of particle mass concentration in producing the observed associations with daily mortality.

Another interesting feature of these studies is the consistent finding of lagged associations between particle exposure and increased mortality. Most of the results presented have reported associations of increased mortality with particle concentrations on the previous day. It would violate a basic tenet of causality if the observed effect were not either concurrent with or lagged behind the exposure. In their analysis of Utah Valley deaths, Pope et al (33) considered longer lag structures up to seven days and found the strongest associations with the five-day moving average, i.e. with the mean PM_{10} of the current day and the four previous days. Thus, these data suggest that mortality effects of particulate air pollution may be lagged by several days.

In summary, a series of time-series analyses of the associations of daily mortality with particulate air pollution has shown a ~1.0% increase in total deaths/day associated with each 10 $\mu g/m^3$ increase in PM_{10} concentration. Stronger associations were observed with cardiovascular disease (1.4% per 10 $\mu g/m^3$ PM_{10}) and respiratory disease (3.4% per 10 $\mu g/m^3$ PM_{10}). The consistency of these estimates across communities suggests that these results are not due to confounding with an unknown or uncontrolled factor and that the mass concentration of the particle mix common to many urban areas, rather than specific chemical species within the mix, may be responsible for the observed associations.

Hospital Usage

If daily mortality is associated with daily particulate pollution levels, then associations with increased hospital admissions and emergency department visits should also be expected. In a unique natural experiment, Pope (28, 29) observed hospital admissions of children for respiratory disease in Utah Valley dropped by over 50 percent during the winter of 1986–87 compared to adjacent years. During this winter, a strike at the local steel mill led to much lower PM_{10} concentrations—a mean of 51 $\mu g/m^3$ and maximum of 113 $\mu g/m^3$ compared to a mean of 90 $\mu g/m^3$ and a maximum of 365 $\mu g/m^3$ in the previous year. Regression analyses estimated a 4.2% decrease in asthma and bronchitis admissions of children and a 7.1% decrease in all respiratory admissions of children associated with a 10 $\mu g/m^3$ decrease in the two-month mean PM_{10} concentration.

Increased rates of respiratory admissions, including asthma, for the years 1974 to 1983 in Southern Ontario have been associated with increased sulfate and ozone concentrations (4). A more recent analysis of hospital admissions for respiratory disorders in Southern Ontario for the summers of 1983 to 1988 (7) found an association with increased sulfate concentrations that was independent of associations with ozone exposures. Both studies have been interpreted as suggesting an association between hospital respiratory admissions and an unmeasured air pollutant correlated with sulfates and ozone. Specifically, the authors have suggested a link to acid aerosol concentrations. Alternatively, these associations may be attributable to particle mass concentrations, another air pollutant not considered in the analyses.

Recently, Thurston and colleagues have reported analyses of hospital admissions for respiratory complaints for Toronto, Ontario (50) and for several cities in New York state (51). Although the focus of these studies is the effects of acid aerosols, effect estimates are reported for various measures of particle exposure (Table 2). Taken together, these studies found an increase in hospital admissions for all respiratory diagnoses ranging from 0.8% to 3.4% (weighted mean, 0.8%) for each 10 $\mu g/m^3$ increase in daily mean PM_{10}. A slightly greater effect was seen in hospital admissions for asthma, ranging from 1.9% to 2.1% (weighted mean, 1.9%) for each 10 $\mu g/m^3$ increase in daily mean PM_{10}.

Emergency department visits also have been analyzed by many investigators, and three studies provided quantitative effect estimates of the effects of particles (see Table 2). An analysis of emergency department visits for asthma in Seattle (42) found an increase of 3.4% associated with a 10 $\mu g/m^3$ increase in PM_{10}. Emergency department visits for chronic obstructive pulmonary disease in Barcelona (48, 49) increased by 1.7% associated with a 10 $\mu g/m^3$ increase in PM_{10}. Emergency department visits in Steubenville (35) increased by 0.5% associated with a 10 $\mu g/m^3$ increase in PM_{10}. The weighted mean of these combined effect estimates was a 1.0% increase in emergency department visits associated with each 10 $\mu g/m^3$ increase in PM_{10}

Asthma

Evidence from hospital admissions and emergency department visits presented above suggests that particle exposures may be directly associated with asthma attacks. Several investigators have considered less severe asthmatic attacks reported by panels of asthma patients. Winter studies of asthmatic children with chronic respiratory symptoms in The Netherlands (34) and of asthmatic adults in Denver, Colorado, (27) both found substantial increases in reported asthmatic attacks associated with particle exposures. An earlier study of sixteen asthma panels in the Los Angeles area (56) reported increased attacks associated with particle exposures but the effect was much lower than in the more recent studies (see Table 3). In part this lower effect estimate may reflect over-control of lagged effects of particles by including the previous day's asthma status in the model. The weighted mean of these three studies, however, gives an effect estimate of 3% increase in asthmatic attacks associated with 10 $\mu g/m^3$ PM_{10}.

The use of bronchodilators also has been evaluated as a measure of exacerbation of asthma in a panel of asthmatics in The Netherlands (34) and in panels of symptomatic children and asthmatic patients in the Utah Valley (31; see Table 3). The weighted mean of these studies gives an estimated effect of a 2.9% increase in bronchodilator use associated with 10 $\mu g/m^3$ PM_{10}.

Lung Function

Lung function is a sensitive indicator of acute response to ozone in controlled exposure and chamber studies (21). Repeated measures of lung function in panels of children also have been used to evaluate the effect of particulate air pollution episodes on children.

Panels of elementary school children in Steubenville had their lung function measured weekly before, during, and after particulate and sulfur dioxide episodes during four periods in 1978 through 1980 (10). Forced Expired Volume in three-quarters of a second ($FEV_{.75}$) was reported to decline following these episodes. There was a suggestion that $FEV_{.75}$ remained depressed for up to two weeks following the episode. A study of weekly lung function measurement of school children in The Netherlands (7a) following a sulfur dioxide and particulate episode in January 1985 reported decreases in Forced Expired Volume in one second (FEV_1), which were similar in magnitude and in lag structure to those observed in Steubenville. Subsequent studies of panels of school children with weekly lung function measurements (17, 18) have also shown decreased FEV_1 associated with daily PM_{10} concentrations.

Analysis of longer lags in The Netherlands panel (17) found a significant association between decreased FEV_1 and mean PM_{10} over the previous seven days. Similarly, in a re-analysis of the Steubenville data, Brunekreef (6) found the strongest association with the mean TSP over the previous five days.

Recently, Pope & Kanner (32) analyzed repeated FEV_1 measurements in a panel of chronic obstructive pulmonary disease patients participating in the Lung Health Study. Measurements were taken 10 to 90 days apart. FEV_1 level was reported to be associated with a 0.2% decrease in FEV_1 for each 10 $\mu g/m^3$ increase in daily PM_{10}

Taken together, these studies found a decrease of between 0.05% and

Table 3 STudies of acute effects of particles on exacerbation of asthma

Measure of asthmatic response	Location and period	Particulate measure	Subjects	% Change in daily asthma response for each 10 $\mu g/M^3$ increase in PM_{10}	Reference

0.35% or a weighted average of 0.15% decrease in FEV_1 associated with each 10 $\mu g/m^3$ increase in daily mean PM_{10} (see Table 4).

Peak flow measurements have been widely used as a simple, inexpensive indicator of acute changes in lung function among asthmatic patients. Weekly peak flow measurements were made in the spirometric studies of school children in The Netherlands (17, 18). In these two studies, peak flow declined approximately 0.16% for each 10 $\mu g/m^3$ increase in PM_{10}.

Daily peak flow measurements have been gathered in a series of recent

studies. In two separate panel studies in the winters of 1989–90 and 1990–91 in Utah Valley (30, 31), panels of school children measured their peak flow daily before going to bed. In both cases, small but significant reductions in peak flow were found associated with mean PM_{10} concentrations that day. In both studies there appeared to be associations between lower peak flow and PM_{10} concentrations for up to five days prior, and stronger associations were found when these lag structures were included in the models. In the second study (30), the estimated effect was about twice as large with the five-day lagged mean compared to the one-day mean PM_{10}.

Similar winter panel studies of school children have been conducted in The Netherlands (34). Effects were observed between evening peak flow and daily mean PM_{10} concentrations, and seven-day mean PM_{10} concentration, which were similar to those observed in Utah.

A panel study of children was conducted in the summer of 1992 in Uniontown, Pennsylvania, (25) to evaluate peak flow changes in an area of high aerosol acidity. Although the strongest associations were found with aerosol acidity, there also was an association between evening peak flow and daily mean PM_{10} that was very consistent with the estimates from other studies.

Comparing the results from these studies of repeated peak flow measurements, there was a decrease of between 0.04% and 0.25% in peak flow (weighted mean of 0.08%) associated with each 10 $\mu g/m^3$ increase in daily mean PM_{10} concentration (Table 4).

In summary, studies of repeated measure of lung function consistently show a small decrement in FEV_1 (weighted mean 0.15%) and peak flow (weighted mean 0.08%) associated with each 10 $\mu g/m^3$ in PM_{10} daily mean concentration. There is a strong suggestion in these data that changes in lung function may reflect the cumulative exposure of several (5–7) days prior to the measurement.

Respiratory Symptoms

Daily diaries of respiratory symptoms, an inexpensive method of evaluating acute changes in respiratory health status, have been widely used in evaluating acute effects of particulate air pollution. In a commonly applied study design, panels of school children recorded the presence of specific respiratory symptoms daily on weekly or monthly calendars. These symptom reports are often aggregated into *upper respiratory symptoms* (including such symptoms as runny or stuffy nose, sinusitis, sore throat, wet cough, head cold, hayfever, and burning or red eyes) and *lower respiratory symptoms* (including wheezing, dry cough, phlegm, shortness of breath, and chest discomfort or pain). In addition, *cough*, the most frequently reported symptom, is often analyzed separately. In this review, symptom reports are presented separately for each of these symptom groups.

The frequency of reported respiratory symptoms was generally taken as their prevalence on any given day, that is, the fraction of participating children reporting a symptom complex on each day. In some cases (41), however, incident cases were reported, where "incidence" required that the child be symptom-free for two days prior to the incident symptom report.

Studies of upper and lower respiratory symptoms have been conducted in Utah Valley (30, 31), The Netherlands (17, 18), in a study of six US cities (41), and Southern California (27a; Table 5).

The combined weighted average from these studies gives an estimated effect of 3.0% increase in lower respiratory symptoms with each 10 $\mu g/m^3$ increase in daily mean PM_{10} concentrations. For upper respiratory symptom reports, the weighted average effect estimate was only a 0.7% increase in upper respiratory symptoms with each 10 $\mu g/m^3$ increase in daily mean PM_{10} (Table 5).

Cough reports were analyzed in three of these studies as well as in a winter diary study in The Netherlands (34), a study of two Swiss cities (5), and the summer diary study in Uniontown (25; Table 5). The weighted mean effect estimate from these studies was a 1.2% increase in cough associated with each 10 $\mu g/m^3$ increase in daily mean PM_{10}.

SUMMARY

Evidence from the selected epidemiologic studies presented in this review suggests a *coherence* of effects across a range of related health outcomes and a *consistency* of effects across independent studies with different investigators in different settings. This compilation also provides insights into the relative magnitude of effects being observed in various studies (Table 6).

Total mortality is observed to increase by approximately 1% per 10 $\mu g/m^3$ increase in PM_{10}. Somewhat stronger associations are observed for cardiovascular mortality (approximately 1.4% per 10 $\mu g/m^3$ PM_{10}), and considerably stronger associations are observed for respiratory mortality (approximately 3.4% per 10 $\mu g/m^3$ PM_{10}). No acute effects are detected with cancer and other nonpulmonary and noncardiovascular causes of mortality. These relative differences in cause-specific mortality are plausible, given the respiratory route of particle exposures.

If respiratory mortality is associated with particulate pollution, then health care visits for respiratory illness would also be expected to be associated with particulate pollution. Respiratory hospital admissions and emergency department visits increase by approximately 0.8% and 1.0% per 10 $\mu g/m^3$

Table 5 Studies of acute effects of particles on respiratory symptom reports

Measure of respiratory symptoms	Location and period	Particulate measure	Sample	% Change in daily symptom reporting for each 10 $\mu g/m^3$ increase in PM_{10}	Reference
Lower respiratory	Utah Valley, UT Winter 1989–90	Daily mean PM_{10}	Children Asthmatics	5.1% (1.1%, 9.3%) 0.2% (−4.2%, 4.8%)	31

PM_{10} respectively. Emergency department visits for asthmatics (3.4% increase per 10 μg/m³ PM_{10}) and hospital admissions for asthmatic attacks (1.9% increase per 10 μg/m³ PM_{10}) are more strongly associated. Asthmatic subjects also report substantial increases in asthma attacks (an approximate 3% increase per 10 μg/m³ PM_{10}) and in bronchodilator use (an approximate 3% increase per 10 μg/m³ PM_{10}).

Less severe measures of respiratory health also are associated with particle exposures. Lower respiratory symptom reporting increases by approximately 3.0% per 10 μg/m³ PM_{10} and cough by 2.5% per 10 μg/m³ PM_{10}. Weaker effects are observed with upper respiratory symptoms (approximately 0.7% per 10 μg/m³ PM_{10}). While lung function provides accurate objective measures, the observed mean effects are fairly modest: approximately 0.15% decrease for FEV_1 or $FEV_{.75}$ and 0.08% decrease for peak flow per 10 mg/m³ PM_{10}. Despite the relatively small size of these lung-function effect estimates, they consistently achieve statistical significance. Moreover, mean changes in lung function may not reflect substantial changes in sensitive individuals.

In this review, changes in health measures are reported for only small changes in daily particulate pollution: 10 μg/m³ increase in PM_{10} concentrations. Because daily concentrations of PM_{10} in some US cities average over 50 μg/m³ and often exceed 100 or 150 μg/m³, the effects of particulate pollution can be substantial for realistic acute exposures. For example, a 1% effect estimate per each 10 μg/m³ increase would produce a 5% increase in the health measure for a 50 μg/m³ increase in PM_{10} concentrations, and a 3% effect estimate would produce a 16% increase. Thus the estimated increase in attacks of asthma (3.0% per 10 μg/m³ PM_{10}) would be 16% for a 50 μg/m³ increase in PM_{10} concentrations.

LIMITATIONS

Mass concentration of inhalable particles is only one measure of a complex mixture of gaseous and particulate air pollution to which people are exposed. In this review the possible contribution of gaseous co-pollutants has been ignored. The mass concentration of PM_{10} includes a wide array of potentially toxic chemical species. It is, therefore, presumptuous to assign these observed health effects solely to the mass concentration of particulates. On the other hand, the consistency of these observed effects across so many communities suggests that, lacking an explicit hypothesis, these associations should be assigned to a nonspecific definition of inhalable or fine particle concentrations common to urban areas.

The physical and chemical characteristics of ambient particles are generally not known and so are impossible to duplicate in controlled animal- or human-exposure studies. Many health effects of particles are thought to reflect the combined action of the diverse components in the pollutant mix. Until controlled animal- and human-exposure studies identify the active component(s) of these complex mixtures and can characterize their underlying mechanisms of toxicity, it is prudent to ascribe health effects observed by epidemiologists to the undifferentiated particle mass rather than to any specific component.

Conversion of various measures of particle concentration to PM_{10} mass concentrations are approximations only, based on results presented in published reports. These conversions are certainly correct within a factor of two and are probably within 20% of the true relationship. Thus, while other reviewers may legitimately argue about specific relationships between the

article measures used in the various studies, the estimated effects would emain remarkably comparable, even assuming other reasonable conversions to PM_{10} mass concentrations.

The results of epidemiologic studies of acute effects of particulate air pollution, particularly those describing associations with cardiovascular mortality, have been called into question because of the lack of a biologically plausible mechanism (52, 53). The linkage between air pollution exposure and acute cardiovascular mortality is not clear. Many authors have suggested that air pollution episodes, like episodes of extreme temperature, high or low, are an additional environmental stress that may cause death in otherwise-compromised patients. Bates (3) has suggested three additional mechanisms by which respiratory and cardiovascular mortality might increase in air pollution episodes: (*a*) acute bronchitis and bronchiolitis may be misdiagnosed as pulmonary edema; (*b*) air pollutants may increase lung permeability and precipitate pulmonary edema in people with myocardial damage and increased left atrial pressure; (*c*) bronchiolitis or pneumonia induced by air pollution, in the presence of pre-existing heart disease, might precipitate congestive heart failure. An alternative explanation is that respiratory causes of death, either primary or contributing, are erroneously reported as cardiovascular. In a summary of a workshop of chronic obstructive pulmonary disease mortality, Speizer (46) observed that chronic obstructive pulmonary disease is considerably underdiagnosed on death certificates. While the specific biologic mechanism for these acute increases in mortality is not clear, the internal consistency of the mortality studies and the external consistency with evidence of acute increases in morbidity measures suggest that these results are not artifacts.

RECOMMENDATIONS

Mortality has always been a key health endpoint in epidemiologic studies, i.e. it serves as a leading indicator for hypothesis generation. It is a well-defined health outcome and mortality data are routinely collected and are readily available for epidemiologic analysis. When the numerous time-series studies of the association of mortality with particulate air pollution are compiled, using comparable measures of effect (% increase) and exposure (PM_{10}) as in Table 1, the consistency of estimated effects becomes clear. When estimated effects of particulate air pollution are similarly combined for other health indicators, the consistency and coherence of results also becomes apparent. These findings highlight the importance of using equivalent exposure metrics and health endpoints in air pollution studies.

Thus, we recommend that researchers report results such that they can be readily compared with previous (and future) investigations. The groupings

of health endpoints considered here present some guidance. Likewise, the reporting of associations with PM_{10} concentrations is important. This recommendation should not be interpreted as a request for regimentation or an attempt to limit innovation. Rather, it is recommended that the associations with common endpoints and PM_{10} exposures be reported in addition to other, potentially more sensitive or specific, indicators of health effect or exposure.

A quantitative effect estimate and its estimated standard error should be reported in all cases. Reports of statistical significance without effect estimates are not very informative. Likewise, correlation coefficients and other unscaled measures of association fail to provide useful information.

Epidemiologic research regarding the health effects of particulate air pollution has been impeded by the lack of daily (or more frequent) particle measurements (8). In communities that are not likely to violate (or that clearly exceed) the NAAQS for particles, PM_{10} measurements are made only once every six days, as required by the EPA (13). Fortunately for epidemiologists, the EPA has required daily monitoring in communities likely to violate the NAAQS for particles. These regulations have had the unanticipated (but beneficial) effect of making feasible new epidemiologic studies of the acute effects of particles. Inasmuch as associations are being observed between daily particle exposures and adverse health effects down to the lowest measureable concentrations, it is recommended that daily PM_{10} concentrations be measured whenever possible. When alternative measures of particle concentrations are used, then a description of the relationship to PM_{10} concentrations should be provided.

Research into mechanisms of the adverse health effects of PM_{10} mass concentrations observed in recent epidemiologic studies needs to be undertaken in controlled exposure studies of humans and animals. It is only through integration of the complementary evidence from laboratory animal and controlled human exposure studies with the results from epidemiologic studies that the risk of particle exposures can be fully evaluated. Nevertheless, these recent epidemiologic studies implicate particulate air pollution as contributing to respiratory morbidity and mortality even at exposure levels below the current NAAQS in the United States.

ACKNOWLEDGMENTS

This review was supported in part by National Institute of Environmental Health Sciences grants ES-00002, ES-01108, ES-04595, and ES-06239; by the Environmental Protection Agency Cooperative Agreement CR816071 and CR 818090; and by the Electric Power Research Institute contract RP-1001. The authors particularly want to thank Gail Fleischaker for her thoughtful and meticulous editing of this manuscript. This review was written

while CA Pope was a Visiting Scientist in the Interdisciplinary Programs in Health, Department of Environmental Health, Harvard School of Public Health.

WOOD SMOKE: EMISSIONS AND NONCANCER RESPIRATORY EFFECTS

Timothy V. Larson and Jane Q. Koenig
Departments of Civil Engineering and Environmental Health, University of Washington, Seattle, Washington 98195

KEY WORDS: respiratory effects, chemical composition, air emissions, air quality, young children

INTRODUCTION

During the past twenty years, the use of wood has become popular as an alternative to conventional home heating fuels. Part of this movement has been due to uncertainty about the availability of fossil fuels. About ten percent of space heating in urbanized areas of the northern United States is from wood burning, with up to fifty percent in some smaller, rural towns (42, 63, 75, 85). Wood is obviously a renewable resource. This attraction is offset, however, by the increased air pollution emissions from wood heating devices compared with devices fueled with oil or gas. As noted initially by Cooper (20), particle and organic carbon emission rates can be as much as one to two orders of magnitude larger in wood heating devices than in oil or gas heating units. Legislation restricting the sale of conventional wood stoves first appeared in Oregon in 1984, followed by nationwide restrictions in 1988. Although rapid progress has reduced emissions in some types of modern wood heaters, older "conventional" wood stoves and fireplace inserts are still the predominant appliance in use today. As discussed later in this document, a number of communities continue to experience elevated levels of wood smoke during the winter heating season. In addition, elevated indoor air pollution levels have been observed in homes with non-airtight or improperly operated wood stoves. As a result, there has been an ongoing interest in the potential health effects of exposure to wood smoke. Several reviews of the health effects of wood smoke have been

Energy management

High-temp SCR competes with DLN combustors Recent installations confirm the viability of high-temperature selective catalytic reduction for a broad range of gas turbines. The zeolite-based catalyst offers several advantages over both vanadia/titania SCRs and dry low-NOx combustors

By W M Rogers and M Durilla, Engelhard Corp Edited by Robert Swanekamp, PE

Selective catalytic reduction systems (SCR) have provided efficient, reliable service in hundreds of installations worldwide. These systems can lower NOx emissions by 80 to 90% with a useful catalyst life of more than five years.

But conventional SCR technology (POWER special report, "Controlling NOx Emissions," May 1993) is limited in one very important way: The typical vanadia/titania catalyst works only in a temperature range of approximately 575 to 800F. Any higher, the catalyst undergoes irreversible changes, losing conversion efficiency and active life.

High-temperature SCR technology was introduced commercially in the late 1980s to overcome the limitations of precious-metal designs. The zeolite-based catalysts, which have been applied to gas turbines as large as 36 MW, offer comparable NOx reduction at operating temperatures up to 1125F. They open up new system design options for gas-turbine facilities (Figure 1).

Applications for high-temperature SCR include simple-cycle gas turbines, cogeneration plant retrofits, and stationary engines.

Most gas-turbine exhaust temperatures exceed 800F, hence conventional SCRs cannot be applied to simple-cycle units.

Existing cogeneration units often cannot accommodate the retrofit of conventional SCRs without expanding the heat-recovery steam generator (HRSG) housing to provide room for the catalyst. A high-temperature SCR, which can be placed in the transition duct between the turbine and HRSG, overcomes this problem.

Even if space allows expanding the HRSG housing, retrofitting a conventional SCR may impair operating flexibility. Cogeneration units that pre-date strict air-quality regulations often feature exhaust bypass dampers upstream of the HRSG to enable simple-cycle operation. If a conventional SCR is retrofit into the HRSG, the unit can no longer operate simple cycle without exceeding emissions limits. In contrast, a zeolite catalyst retrofit upstream of the bypass dampers allows simple-cycle operation without sacrificing compliance.

Additional benefits

Beyond its ability to withstand high temperatures, a zeolite-based catalyst has two other significant attributes: Unlike a conventional SCR catalyst, its conversion efficiency increases as (1) inlet NOx concentration increases and (2) exhaust water concentration decreases. These attributes lead to four major benefits; they:

-- Allow operators to reduce or even eliminate water/steam injection into the combustor--reducing potential erosion problems, extending combustor life, and lowering gas-turbine maintenance costs.

-- Make the application of lower-cost, high-NOx-emitting gas turbines a viable alternative.

-- Extend the application of dry low-NOx (DLN) combustors with exhaust emissions in the 25-ppmv range.

-- Make practical the attainment of 5-ppmv NOx emissions at the stack for meeting extremely tight permitting requirements or for banking emissions credits.

Key design issues

Design issues for high-temperature SCRs are similar to those for all SCR technologies:

-- Uneven flow distribution--caused by gas swirling out of the turbine or being deflected in exhaust ducts with severe bends. The more uneven the flow distribution, the larger the volume of catalyst needed to maintain performance. Flow distribution in the range of + or - 15% across the catalyst inlet face is a common design specification for precious-metal and zeolite-based SCRs. Computer simulation or model testing sometimes is required, and may reveal the need to reshape the exhaust ducting or install turning vanes.

-- Ammonia and NOx must mix together in the proper ratio at the active catalyst site. If insufficient mixing occurs, both gases will pass through the system unreacted, potentially forcing permit violations of NOx and ammonia slip. Ammonia/NOx mixing at 5% standard deviation is a typical design specification. The more stringent the performance requirements, the more critical this

deviation becomes.

-- Requirements for space velocity--defined as the gas flow rate per unit volume of catalyst (SCFH/ft superscript 3)--vary widely depending on the particular turbine and catalyst. To achieve a given level of performance, a highly active catalyst requires only a small volume. Hence, the highly active catalyst can operate at a higher space velocity. Conversely, a less active catalyst will require a larger catalyst volume, and thus must operate at a lower space velocity.

Many factors affect the selection of a design space velocity, including turbine fuel, NOx conversion required, ammonia slip constraint, process temperature, desired service life, and degree of ammonia/NOx mixing.

-- A catalyst in the exhaust stream increases system backpressure, and lowers net turbine output. Therefore, designers strive to minimize back pressure. But trade-offs must be made.

For example, frictional losses through the catalyst vary with the square of gas velocity. A larger duct cross section will reduce velocity, but will also occupy more plot space and cost more money.

Frictional losses also vary in direct proportion to system temperature. Recall that catalyst activity, for zeolite-based systems, also increases with temperature. Hence, the zeolite SCR's catalyst volume can be reduced at higher operating temperatures, helping to offset pressure drop.

Another trade-off is in cell density of the honeycomb catalyst. The lower the cell density, the lower the pressure drop. However, the catalyst volume must increase to achieve comparable NOx-conversion and ammonia-slip performance.

Recent installations

A variety of gas-turbine projects currently are using high-temperature SCR technology, demonstrating levels of NOx reduction, ammonia consumption, and ammonia slip similar to conventional catalysts (table). One recent project features both a high-temperature SCR and a CO catalyst. The system was retrofit into a cogeneration unit comprising a 2.8-MW Centaur GS4000 gas turbine/generator, supplied by Solar Turbines Inc, San Diego, Calif. Exhaust temperatures range from 600 to 872F. The retrofit allows the unit to meet emissions limits, even when the HRSG is off-line.

The high-temperature SCR/CO system was installed in a 17-ft transition area between the turbine exhaust flange and an existing HRSG bypass damper. The system is designed to meet a 75% NOx conversion requirement, reducing the inlet NOx from 36 to 9 ppmv

and allowing 10 ppmv ammonia slip. Exhaust flow from the turbine is extremely turbulent, so a perforated plate is placed near the turbine exhaust flange to better distribute flow to the CO catalyst. The CO catalyst further streamlines the exhaust flow for proper ammonia/NOx mixing upstream of the SCR catalyst.

Frame units also

A high-temperature SCR was selected over a DLN combustor for retrofit to a Frame 6 gas turbine, manufactured by GE Industrial & Power Systems Co, Schenectady, NY. The high-temperature SCR was installed upstream of an existing HRSG bypass damper, subjecting it to an exhaust temperature of 992F. The new system reduces NOx by more than 94%--to 9 ppmv--with ammonia slip below 10 ppmv.

Because high-temperature SCRs are relatively new, it is too early to precisely define their life expectancy. Data gathered to date, however, support offering warranty periods comparable to those for precious-metal catalysts.

POWER PLANT PROFILES: HANES MILL ROAD PROJECT

Extraction, collection, compression are keys to landfill gas project The gas turbine is the least of the worries when converting landfill gas to electricity. Getting fuel to the machine is the challenge, met successfully here

Landfill gas-to-energy projects have grown nearly 50% since 1991, spurred by environmental regulations, tax incentives, and competitive pressures (see box, p 94). Reflecting this trend is the Hanes Mill Road project, a 4.3-MW powerplant co-developed last year by Biomass Energy Systems, Ann Arbor, Mich; Sherdyne Power Systems, Charlotte, NC; and Landfill Energy Systems, Wixom, Mich (Fig 1).

The gas-turbine-based plant recovers nearly 1-billion ft3 of gas per year from a landfill owned by the city of Winston-Salem, NC, and sells electricity to Duke Power Co, Charlotte, NC, under a 15-yr contract. As evidence of the earnestness of landfill-gas project developers, consider that Biomass Energy Systems is a subsidiary of DTE Energy Co, owned by Detroit Edison Co.

Packaged gas turbine The Hanes Mill project, which started up last July, comprises a 4.3-MW gas turbine/generator, manufactured and packaged by Solar Turbines Inc, San Diego, Calif (Fig 2). The turbine typically fires 100% landfill gas, but No. 2 diesel fuel is available as backup. The plant has demonstrated the ability to switch smoothly between fuels "on the fly."

Because landfill gas is extracted and collected around the clock, the Hanes Mill turbine is designed for base-load operation. The gas must still be flared, as it was before the turbine was installed, whenever the plant is down for maintenance (Fig 3).

Extraction, collection are key Extraction and collection of landfill gas are critical to a project's success, because the bacteria in the decomposing garbage will only produce a certain amount of gas over a specific period of time. If the system is oversized and too much gas is pulled from the landfill, excessive O2 will be drawn into the pile and kill the bacteria. If the system is undersized, energy will be wasted, impairing the project's economics.

The landfill-gas extraction system at Hanes Mill, designed by SCS Engineers, Richmond, Va, has over 21,000 linear feet of collection piping and vertical transport lines made of high-density polyethylene (HDPE), which carry the gas from 112 extraction wells. The lower portion of each extraction-well casing is slotted to provide for 8 in.3 of opening per linear foot for methane extraction. Set at an average depth of 50 ft, each of the vertical extraction wells is fitted with a flexible, commercial wellhead that allows for landfill subsidence and provides fittings for technicians to "balance" the system (Fig 4). According to facility manager Bob Biskeborn, a technician attends to each well twice weekly to verify methane, CO2 ,O2, and N2 concentrations.

Unique compression system A sorespot with many landfill-gas power projects is the gas compression and treatment system. Landfill gas is approximately 50% methane, 30% CO2, 10% N2 (which is drawn into the mix from the atmosphere when vacuuming gas into the collection systems), and 10% other chemical compounds. Many of these "other" compounds are destructive to plant machinery.

Probably the worst compounds are the total organic halides expressed as chloride (TOH/Cl), formed from the decomposition of household and industrial cleaning products. The TOH/Cls combine with water to form hydrochloric and other acids that wreak havoc on valves, pistons, cylinders, combustors, and so on. Landfill gas also contains an abundance of water, which combines not only with the TOH/Cls, but with oxides of nitrogen to form acids that harm systems downstream of the combustion process.

Concerned about the compression/treatment process, Biomass Energy Systems specified what it calls a unique system that delivers high-quality fuel and accommodates the gas turbine's high fuel-flow and -pressure requirements. The modular, skid-mounted system has a 2250-scfm design rating, with two electric-motor-driven rotary compressors. The first compressor provides 8 in. Hg of vacuum for gas extraction. The second compressor delivers fuel at 225 psig to the gas-turbine combustor.

The extracted and unfiltered landfill gas is initially collected in a coalescer vessel, before being piped to the first compressor. There, a 350-hp electric motor drives a positive-displacement rotary blower, designed to operate at a differential pressure up to 18 psig, to discharge landfill gas at approximately 230F/9 psig. From the discharge of the first compressor, the landfill gas is then directed to an intercooler and inter-stage coalescer to separate condensate.

The landfill gas next flows to the second stage of compression, where an 800-hp flooded-screw-type compressor boosts pressure to 225 psig and raises temperature to 236F. Lube oil is then injected into the compressor gas path at a rate of approximately 90 gal/min. This oil injection serves to cool the compressor, and also to strip all suspended particles before the gas/oil separator. The separator vessel doubles as the compression

train's sole reservoir of lube oil for all rotating components.

Gas exiting the gas/oil separator passes through a shell-and-tube heat exchanger where it is again air-cooled for condensate separation, before being delivered to the gas turbine at a warm, dry 135F.

Plant performance Since startup last June, the Hanes Mill plant has operated well, Biskeborn reports, selling nearly 9000 MWh to Duke Power Co. The veteran facility manager offers several observations based on his experience at Hanes Mill and other landfill-gas projects:

-- The power generation equipment itself firing landfill gas, whether based on gas turbines or reciprocating engines, can deliver high capacity and availability factors, as long as fuel is available.

-- Problems with the wellfield collection system account for most of the operation and maintenance difficulties, and nearly all of the plant downtime.

-- Reciprocating engines, which comprise nearly two-thirds of the landfill-gas power projects in the US, enjoy a slight advantage because of their simpler fuel-gas compression requirements. This translates into fewer maintenance hours and lower parasitic power losses.

ABSTRACT. The Miron Quarry municipal solid waste landfill site in Montreal, Québec, generates copious quantities of methane and other gases, including a rich mixture of volatile organic compounds, some of which are recognized or suspected human carcinogens. The site is the third largest in North America and is located in the center of a densely populated area. Using data from the Québec Tumour Registry, we conducted Poisson regression analyses to evaluate whether cancer incidence among persons who lived near the site was higher than expected. Potential exposure to ambient air pollutants from the site was defined in terms of a set of geographic exposure zones proximal to the site. A set of reference areas distal from the site was selected to be similar to these exposure zones with respect to several key sociodemographic factors. Risk ratios (RRs) were adjusted for age and calendar year. Among men living in the exposure zone closest to the site, elevated risks were observed for cancers of the stomach (RR = 1.3, 95% confidence interval [95% CI] = 1.0–1.5); liver and intrahepatic bile ducts (RR = 1.3, 95% CI = 0.9–1.8); and trachea, bronchus, and lung (RR = 1.1, 95% CI = 1.0–1.2). Among women, rates of stomach cancer (RR = 1.2; 95% CI = 0.9–1.5) and cervix uteri cancer were elevated (RR = 1.2, 95% CI = 1.0–1.5), but breast cancer incidence was less than expected (RR = 0.9, 95% CI = 0.9–1.0). Prostate cancer was also elevated in one of the proximal exposure subzones (RR = 1.2, 95% CI = 1.0–1.4). Further studies at this and at other landfill sites are needed to confirm or refute these observations.

IN 1968, the Miron Quarry municipal solid waste (MSW) landfill site in Montreal, Québec, opened as a repository for domestic, commercial, and industrial wastes. At that time, little attention was given to the environmental and health consequences that might occur from the landfilling of refuse in an urban area. This may have been a serious oversight because there are about 100 000 persons who now live within 2 km of what is currently the third largest MSW landfill site in North America. The site has an area of about 750 000 m²; a depth of 50–80 m; and, in January 1993, it was estimated that the site contained about 36 million tons of domestic, commercial, and industrial waste. Because the site is still in operation, it has not been capped.

The chief environmental problems are the amount of toxic chemicals on site, the production of liquids (leachates), and vapors and gases (biogas). Although leachates can contaminate underground water supplies,

this is not a primary health concern because Montreal obtains its potable water from other sources. The main health considerations derive from the release of biogas into ambient air and soil. Other exposures include noise, diesel fumes, and dust.

Biogas is generated by anaerobic decomposition of organic compounds and by other processes.[1] It is a complex chemical mixture composed mainly of methane and carbon dioxide, but it also contains important quantities of volatile organic compounds and sulfur-based substances[1–5] (Table 1). Biogas is associated with pungent odors.

Since 1980, the biogas has been collected through a network of pipes, but the system has operated at low efficiency. After collection, the biogas is burned but combustion is incomplete. Information from other MSW landfill sites[6–9] suggests that the combustion products include nitrogen oxides, carbon dioxide, carbon monoxide, sulfur dioxide, and hydrochloric acid; it is also possible that dioxins, furans, and other volatile organic compounds are released.

Given the concerns for health expressed mainly by residents who live near the site, the city of Montreal commissioned the Public Health Department in 1991 to conduct a cancer-risk assessment study of the site. The justification for this study was that a number of volatile organic compounds found in the biogas were recognized or suspected human carcinogens. Concentrations of the constituents of the biogas, measured within the biogas capture system,[5] are shown in Table 1. Thirty-five volatile organic compounds were identified, including the recognized human carcinogens benzene and vinyl chloride monomer and the suspected human carcinogens methylene chloride, chloroform, 1,2-dichloroethane, bromodichloromethane, tetrachloroethylene, 1,4-dichlorobenzene, 1,2-dibromoethane, and carbon tetrachloride.[10,11]

There are minimal data that indicate the extent of exposure to biogas within the community, although residents who live up to about 1.5 km from the site have complained frequently of odors, and spot measurements of methane on streets of Montreal near the site resulted in concentrations that ranged from 0 to 25 ppm.[15] The presence of odors near MSW sites is not unusual.[1,12–14] Lateral migration of biogas through the ground is also a concern,[16,17] although we have no information regarding this potential route of exposure.

In addition to the ongoing cancer-risk assessment study, two epidemiologic studies have been completed and others are in progress. In one study, we found a 20% increase in the frequency of low birthweight (i.e., < 2 500 g) among children born to women who lived proximal to the site.[18] In the current study, we describe the second investigation,[19] the purpose of which was to determine if rates of cancer during the period 1981–1988 among persons who lived near the Miron Quarry MSW landfill site were higher than expected.

Table 1.—Concentrations of Selected Constituents of the Biogas, as Measured in the Biogas Collection System of the Miron Quarry Municipal Solid Waste Landfill Site, Montreal, Quebec

Chemical	Range of concentration in biogas collection system*
Methane	~ 50%
Carbon dioxide	~ 50%

Material and Method

Definition of exposure zones. Given the lack of environmental exposure data, we carried out the analyses of cancer incidence rates according to a set of three areas proximal and distal to the quarry. These zones were formed by grouping contiguous or nearly contiguous three-character postal-code areas. These zones are hereafter referred to as the low-, medium-, and high-exposure zones (Fig. 1).

The high-exposure zone comprised the postal-code area in which the quarry is located and the postal-code areas that border it. This zone included an irregular region (about 28 km²), ranging from approximately 2–4 km distant from the edge of the site. The medium-exposure zone included all postal-code areas that bordered the high zone on the north, south, and east sides but excluded two postal-code areas in the east that were ≥ 4 km distant from the site. The low-exposure zone included all postal-code areas located northeast of the medium and high zones.

In addition, the high-exposure zone was divided into

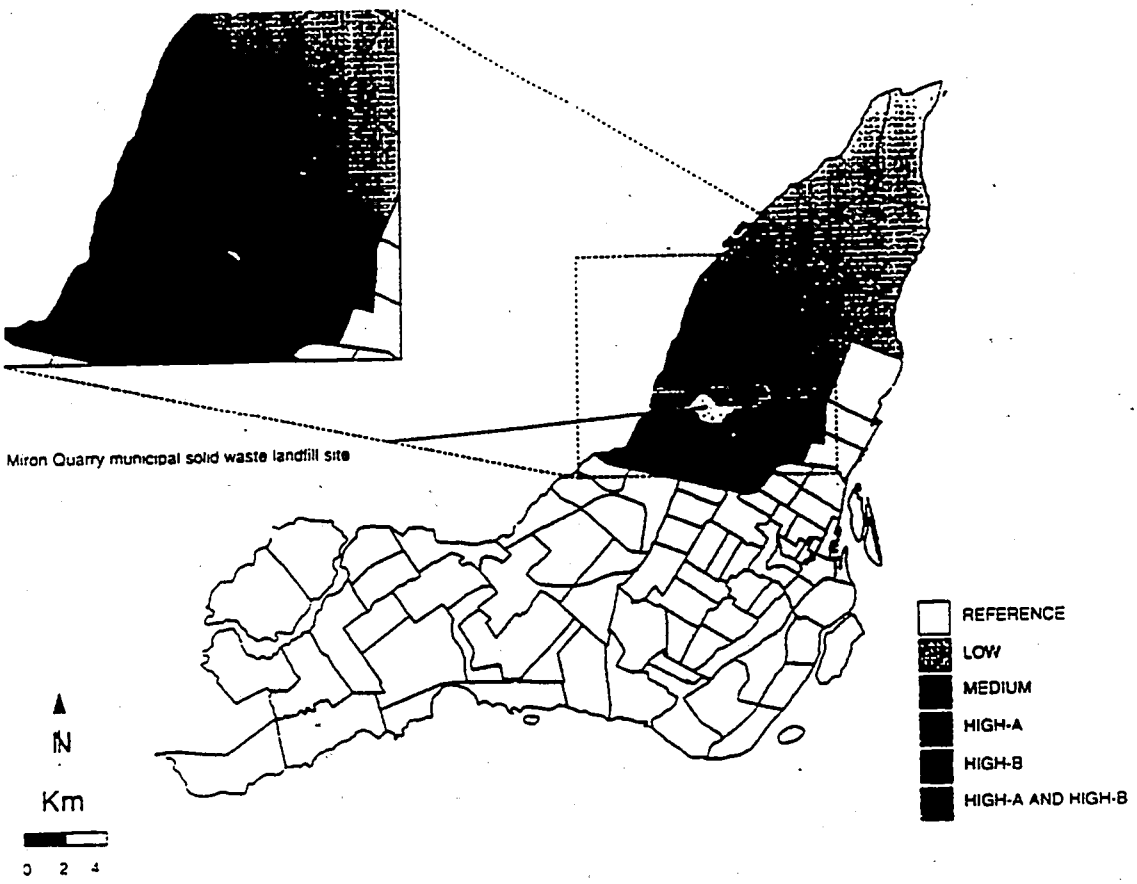

Fig. 1. Definition of the exposure zones surrounding the Miron Quarry municipal sold waste landfill site, Montreal, Québec.

two subzones (referred to as high-A and high-B; Fig. 1) so that prevailing winds could be accounted for. These two subzones were not mutually exclusive in that they both included the postal-code area in which the quarry is located.

Separate analyses were conducted for these four exposure zones, using four different referent zones, as follows:

Exposure zone	Reference zone
High, medium, low	Reference-1
High	Reference-2
High-A	Reference-3
High-B	Reference-4

The first reference zone (reference-1) comprised all "nonexposed" areas on the Island of Montreal. It was not entirely comparable sociodemographically to the three exposure zones (Table 2). For the three other exposure zones, we created separate reference zones from subsets of the unexposed areas of Montreal; therefore, these reference zones were similar to the high-exposure zones with respect to average household income, proportion of immigrants, and the proportion of persons whose native language was French. Similar proportions between exposure and reference zones for these factors, except for the proportion of French-speaking persons in the reference-3 zone, are shown in Table 2. As well, there were similar proportions of women and men; blacks; and persons who (a) rented their homes, (b) were below the poverty line, (c) were unemployed, (d) were < 4 and > 65 y of age, and (e) had not moved subsequent to the 1981 census. There were, however, differences in the proportion of persons with Italian ancestry, those with less than grade 9 education, and those having a university education.

Cancer incidence. Incident cases of cancer among persons who lived on the Island of Montreal at the time of diagnosis during the 8-y period from 1981 to 1988 were identified from the Québec Tumour Registry (Minister of Health and Social Affairs, Québec). The Registry relies solely on hospital discharge reports submitted by each hospital's medical records office. Since 1981, all Québec hospitals forwarded their discharge reports to a central collection and processing system known as Med-Echo.[20] Each hospital that reported to Med-Echo was responsible for the abstraction, coding, and verification of their own data; data verification was also carried out centrally, as was internal record linkage to distinguish prevalent from incident cases. The coding

of discharge diagnoses was not done by physicians but by trained nosologists at each hospital, using information on a summary sheet kept with the patient's chart. This summary sheet contained relevant diagnostic information recorded by the treating physicians. Information on sociodemographic factors was provided, usually by patients or by next-of-kin, and this information was recorded on the hospital discharge form.

The following information was used: date of birth; age at time of diagnosis; sex; three-character postal code of subject's residence at time of discharge; date of discharge (used as surrogate for date of diagnosis); and four-digit topological code, according to the ninth revision of the International Classification of Diseases (ICD9). The major sites of cancer, as well as a number of smaller a priori sites, were retained for the statistical analysis (Table 3).

Estimates of the population. Data from the Canadian censuses for 1981 and 1986 were used to estimate the size of the population, by sex and age, for each exposure and reference zone. With respect to the years 1981 and 1986, exact numbers provided by the census were used. For the intervening and following years, we conducted linear interpolation and extrapolation, respectively.

Statistical methods. Cancer cases were assigned to the exposure or reference zones, according to their postal code at time of discharge from hospital. For each site of cancer, we tabulated the number of incident cases, according to sex, 5-y age groups, calendar year, and residence in the exposure or reference zones. Rates in each zone were calculated by dividing the number of incident cases by the corresponding estimates of the population at risk.

It was assumed that incidence rates followed a Poisson distribution.[21] Multiplicative Poisson regression models that included age and calendar year as covariates were developed to estimate adjusted relative risks between exposed and reference zones. Poisson regression is a generalization of indirect standardization. It is a maximum likelihood procedure that can account for potential confounding factors and can allow the assessment of statistical interactions. We calculated 95% confidence intervals (95% CI), assuming that the log relative risks were distributed normally. Separate analyses were carried out for men and women. Statistical interactions between age and exposure zone and year and exposure zone were assessed with the likelihood ratio goodness-of-fit test, based on hierarchical models.[21,22] There were no significant statistical interactions between geographic region and age or calendar year for any site of cancer.

Results

Shown in Table 3 are the number of incident cases for the 17 sites of cancer among men and the 20 sites of cancer among women, according to exposure and reference zones for the entire Island of Montreal during the 8-y period 1981–1988. Of the 68 analyses conducted for men and the 80 analyses carried out for women, significant (95% CI excluding unity) or nearly significant positive associations (lower 95% confidence limit > 0.95) in the high-exposure zones were observed for two sites of cancer in women and four sites in men (Table 4). It should be noted that because the high-A and high-B exposures zones overlapped, the total number of cases in these two subzones was greater than the number in the high-exposure zone.

Rates of stomach cancer and cancer of the cervix uteri in women were in excess. Rates of breast cancer were, however, significantly less than expected. Among men, cancer of the stomach; cancer of the liver and intrahepatic bile ducts; cancer of the trachea, bronchus, and lung; and cancer of the prostate were higher than expected. Except for cancer of the liver and intrahepatic bile ducts, most excess relative risks for the high-exposure zones were quite low (i.e., < 1.3).

With respect to stomach cancer, relative risks between 1.04 and 1.27 were observed in the high-exposure zones. The pattern of risks was similar in men and women. In the high-exposure zone, there was little difference in relative risks between the reference area encompassing all other areas of Montreal (reference-1) and the "matched" reference zone for the high-exposure zone (reference-2). It was also observed that most of the excess risk was restricted to the high-A subzone, which was predominantly downwind from the site.

Analyses of cancer of the liver and intrahepatic bile ducts showed considerable differences between the sexes. These differences may have resulted from statistical variability, especially because there were few cases among women. For men, the relative risks in the high-exposure zone decreased from 1.55 when all of Montreal was used as a reference zone (reference-1) to 1.31 when a more sociodemographically comparable reference zone was used (reference-2). As was observed for stomach cancer, most of the excess risk was restricted to the high-A exposure zone (RR = 1.79, 95% CI = 1.21–2.64). The pattern of risks for women in the high-exposure subzones was directly opposite to that observed in men, although there was considerable variability in the estimates; the RR for the high-B exposure zone (RR = 1.54, 95% CI = 0.62–3.51) was higher than for the high-A zone (RR = 1.06).

There were no excess risks of lung cancer observed among women. For men, however, significantly high risks relative to the general population (reference-1) were observed in the low-, medium-, and high-exposure zones, with the lowest risks found in the high-exposure zone (RR = 1.11, 95% CI = 1.04–1.19). The RRs for the high-exposure zone were slightly lower when a matched reference zone (reference-2) was used (RR = 1.06, 95% CI = 0.98–1.16). Risks in the high-A zone were significantly different from unity (RR = 1.15, 95% CI = 1.04–1.29), and no excesses were detected in the high-B zone.

*Ninth revision of the International Classification of Diseases.

We did not observe an association between prostate cancer and living in the high-exposure zone. This null result, however, resulted from a significantly decreased risk in the high-A exposure zone (RR = 0.85, 95% CI = 0.73–0.98) and from a significantly elevated risk in the high-B exposure zone (RR = 1.18, 95% CI = 1.02–1.37).

Significantly elevated RRs of 30% and 23% were observed for cancer of the cervix uteri in the medium- and high-exposure zones, respectively. The RR for the high-exposure zone was not influenced by the choice of reference zone; however, risks for the two high-exposure subzones dropped dramatically and were non-significantly different from expected (RR = 1.07 and RR = 1.04 in the high-A and high-B zones, respectively).

Of all the sites of cancer considered, only female breast cancer showed a significant deficit in the high-exposure zone. The RRs for this exposure zone were invariant with respect to the reference zone used (RR = 0.92), but risks were lower in the high-A zone (RR = 0.88, 95% CI = 0.79–0.97) than in the high-B zone (RR = 0.95, 95% CI = 0.86–1.06).

Discussion

The results of this study suggest that there may be increased risks for cancers of the stomach, liver, lung, prostate, and cervix uteri among persons who live near the Miron Quarry MSW landfill site. Prior to considering these results in more detail, the relevant methodologic aspects of this study will be discussed.

A strength of this study was that a population-based cancer registry was used to identify incident cases. Residents of Québec treated out of province were not, however, included in the database unless they were hospitalized in Québec. Therefore, although there may have been some underreporting of cases, it is unlikely that this underreporting would be associated with area of residence because of Canada's universal health-care system and because of the similarity of the exposure and reference zones on sociodemographic factors, notably average income.

We are unaware of any studies in which the reliability of the data retained in the Cancer Registry's files has

Notes: No. = numbe. of cases, RR = relative risk, and CI = confidence interval.

been investigated. Errors can occur during the coding of diagnoses because of incorrect interpretations of the diagnostic summary form retained in the hospital chart or in the transcription of information onto computer files. A recently completed reliability study of respiratory and other diseases, based on discharges from hospitals (Med-Echo system) in Montreal from which the Tumour Registry derives its data, has shown that diagnosis, age, sex, year of admission, municipality codes, and postal codes were recorded quite accurately.[27] Indirect evidence regarding the accuracy of the diagnoses for those sites of cancer presented here is provided by the similarity between Montreal and other jurisdictions of age- specific incidence rates[28] and the ratio of male-to-female cancer cases.[29,30] It is, therefore, likely that the data from the Tumour Registry are sufficiently accurate for the purposes of the analyses presented here and that they are superior to data retained in mortality records, for which the accuracy of diagnosing cancer has been estimated at about 80%.[31,32]

The main limitations of this study were related to potential errors in exposure classification, to inadequate control of potential confounding factors, and to a relatively short period from first exposure (1968) to cancer onset (1981–1988).

Because no direct measurements of biogas were available, we defined exposure zones in terms of proximity to the site. This probably led to misclassification because it was likely that there was heterogeneity in actual exposures to biogas in these broad areas. In an attempt to distinguish between "downwind" and "upwind" areas, the exposure zone closest to the site was divided into two subzones. Our results for stomach cancer in men and women and for liver cancer and lung cancer in men were consistent with the assumption that these subzones represented different average exposure levels, although results for prostate cancer did not.

Because exposure data were unavailable, we were unable to directly assess cancer incidence in relation to exposure to biogas.

Other than age and sex, potential confounding factors could not be controlled directly in the statistical

analyses. Indirect control over a number of key sociodemographic factors was, however, achieved through the matching of exposure and reference areas. Because the exposure zones were fairly broad, we could not match as closely as we would have liked (e.g., the high-exposure zone was different from the reference-2 zone with respect to percentages of Italian-speaking persons and in level of education). This difference in the proportion of persons of Italian extraction may have had a bearing on the results for stomach cancer. A study by Terracini et al.[13] showed a statistically significant increased risk of stomach cancer among Montreal males of Italian origin. However, adjustment for socioeconomic status and urban residence in childhood reduced the differences considerably. It was not possible, however, to evaluate formally the magnitude of these potentially distorting effects.

One of the analyses dealt with the comparison of cancer incidence rates for the high-, medium-, and low-exposure zones with respect to the remaining areas of Montreal. These comparisons should not be interpreted as being representative of exposure- or distance-response relationships because it is unknown to what extent, if any, biogas migrated into the medium- and low-exposure zones. It is nonetheless difficult to interpret the results for stomach cancer in men and women and lung cancer in men because they showed excess risks in the low- and medium-exposure zones, as well as in the high-exposure zone. For lung cancer, the excess risks may have been caused, for example, by a greater frequency of cigarette consumption or, for the low- and medium-exposure zones, by emissions from petroleum and petrochemical plants located in the east end of Montreal. Results from previous environmental studies near petrochemical plants have not, however, been consistent in indicating excess risks for lung cancer.[21-25]

No data were available regarding residential history; therefore, it was not possible to determine the length of time that subjects had lived in the relevant geographic areas. Given that the site has been in operation since 1968 and the cancer data cover the period 1981–1988, latency and exposure periods overlapped. Moreover, the maximum latency period was only 20 y, which, for solid tumors, is quite short.[26]

Some or all of the positive findings may have arisen because of multiple testing. Including all four exposure zones, 80 and 68 tests were carried out for women and men, respectively. Because these tests were not independent, it is difficult to predict the number of associations that would be expected solely by chance. Focusing on the analyses of the high-exposure zone, using only the reference-2 zone and assuming a 5% level of statistical significance, one would have expected to detect about one significant association for men and one for women. We observed one excess positive association among women and one among men.

The large difference in rates between men and women for liver cancer is consistent with that observed usually; women tend to have a higher incidence of gallbladder cancer and a lower incidence of liver cancer than men.[27,28] The increased risk in liver cancer among men is intriguing given that vinyl chloride monomer—a recognized liver carcinogen[29,30]—is present in the biogas. However, the excess risks may have resulted from other risk factors (e.g., alcohol consumption, aflatoxin exposure, and hepatitis-B virus). Risks among women were also greater than unity, but there was considerable variability in the estimates.

It would be useful to compare our estimates of RR with those obtained from calculating the expected number of excess cancers attributable to exposures to specific agents, using, for example, lifetable methods and available dose-response coefficients[14] (e.g., IRIS slopes[31]). This is the subject of our risk-assessment study mentioned above, which will be completed when environmental measurements have been carried out.

Conclusion

This is the first study in which cancer incidence was assessed in a population living near an active MSW landfill site. Because of the unavailability of detailed environmental data to define exposure areas and the absence of some important potentially confounding variables, we cannot conclude whether the excess risks for cancer observed here represent true associations with exposure to biogas. The results from this investigation will, however, be used in conjunction with other studies that will be carried out at the site.

Additional studies are warranted. There are approximately 6 000 MSW landfill sites currently in operation in the United States,[4] and, given that since World War II almost all communities in North America have used this method of solid waste disposal,[15] there must be an enormous number of inactive sites. Although MSW landfill sites were usually situated outside of urban areas, many sites are now in close proximity to large populations. The potential toxicity of emissions from MSW landfill sites is underscored by the fact that many are classified as hazardous; by 1986, 187 of the 850 sites proposed for the American superfund priority list for remedial action were of this type.[16]

LOW BIRTHWEIGHT, EARLY BIRTHS FOUND AMONG INFANTS NEAR HAZARDOUS LANDFILL

In a study that may have far-reaching implications for people living beside hazardous chemical waste sites. two scientists today reported that infants born to mothers living immediately adjacent to a New Jersey landfill at the height of its activity had substantially lower birthweights and as much as twice the risk of being born preterm.

Epidemiologists Michael Berry. currently with the New Jersey Department of Health and Senior Services. and Frank Bove of the federal Agency for Toxic Substances and Disease Registry. which partly financed the study, reported their findings in *Environmental Health Perspectives*, the monthly* journal of the National Institute of Environmental Health Sciences.

The report is based on data collected from residents of four municipalities that border the Lipari landfill. a 15-acre site located in Gloucester County that was used for the dumping of household and industrial wastes from 1958 until 1971. The landfill was once rated number one on the Environmental Protection Agency's priority list. a national ranking system for hazardous waste sites based on the health risks they pose to surrounding populations.

The researchers divided the infants' mothers into "exposure categories" based on the distance of their residences from the landfill. Those who lived within a one-kilometer radius of the landfill (slightly more than six-tenths of a mile) were placed in the "exposed" category; those who lived beyond this boundary constituted the "unexposed" group. To assess the effects of chemical exposure on those who lived immediately downwind from the landfill. the investigators conducted separate analyses on the residents located directly adjacent to the site.

The researchers found that the average birthweight of infants born in the "exposed" area was 65 grams (more than two ounces) less than that of the infants born in the "unexposed" group. Then they discovered the birthweight differences were concentrated in the residential area nearest the landfill—these infants were. on average, 141 grams (more than four ounces) lighter than their "unexposed" counterparts. They also found that infants born in this residential area had twice the risk of being born preterm (gestational age less than 37 weeks) compared to the unexposed controls.

These effects occurred only among those infants born between 1971 and 1975. the period corresponding to the heaviest runoff of hazardous materials and the greatest likelihood of chemical exposure to nearby residents. Neither the infants born before. when dumping had not yet reached its peak. nor those these born afterward, when dumping had ended and remedial cleanup had begun, were similarly affected.

"The magnitude of this effect is about as bad as the birthweight reduction that is associated with cigarette smoking during pregnancy," said Berry, the lead investigator. "These findings are quite significant given the fact that low-birthweight and preterm babies have a lower chance of survival and a greater risk of developing post-birth problems than those born within the normal range."

Developed as a joint venture between the New Jersey Department of Health and community leaders

and activists. the study was designed to address the concerns of nearby residents to toxic chemicals emanating from the hazardous waste landfill. Infant birthweights were selected for study because they are an objective indicator of infant health. and because the information could be readily obtained from birth certificates. The researchers took into account potential risk factors such as maternal age and education. previous pregnancies and prenatal care. but other factors. such as maternal health. and cigarette and alcohol consumption during pregnancy. were not included on the birth certificate and could not be evaluated.

First excavated as a source of sand and gravel. the Lipari landfill was later back-filled with municipal waste. household wastes. liquid and solid chemical wastes. and other industrial wastes. These included cleaning solvents. resins. paint and paint thinners. ester press cakes. phenol wastes and amine wastes. Operation of the landfill ended in 1971 because of nearby residents' complaints regarding odors. respiratory problems. headaches. nausea. and dying vegetation.

In 1985. a remedial investigation of the Lipari landfill conducted by EPA revealed hazardous levels of a chemical called bis chloroethyl ether (BCEE). Other chemicals identified by the investigators included benzene. toluene. methylene chloride. dichloroethane, formaldehyde, phenol. chromium. nickel. mercury. lead. selenium, arsenic, and silver.

The researchers said. "The real public health threat to residents near the contamination was likely due to volatile organic compounds—chemicals such as benzene and xylene that evaporate into the air and thus expose people nearby." Both have been associated with low birthweight in some animal studies.

Other studies have linked low birthweight offspring to men working with auto body solvents and working mothers exposed to polychlorinated biphenyls (PCBs). Low birthweight (an average decrease of 50 grams) was also shown in the newborns of homeowners in the Love Canal. N.Y.. neighborhood.

* This is the August issue of the journal. which was delayed by publishing difficulties until today.

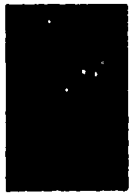
WHAT'S WRONG WITH THIS PICTURE?



EXH. 76

Richard Alarcon, Los Angeles city councilman, 7th District

"We need a lot more to upgrade the r ly the year 2003, the life of a ndfill will have expired. When that happens, we'll need to negotiate with another agency to dispose of our trash if anything, we should leave space open to allow us room to negotiate with that agency."

Richard Alarcon

Lander Warren

Lander Warren, administrator of Forester Haveoe Senior Home, San Fernando

"Our grounds are [less than a mile] away from the landfill. Because of the intermittent odors and fumes coming out of there, our residents have experienced frequent headaches, burning eyes and exacerbated problems with breathing. We use buses to get people to the doctor or the hospital and, at times, are forced to wait for five trucks to go by before we can get through. Along with the noise, that is a nuisance."

Drew Sones, assistant director of the Los Angeles Bureau of Sanitation

"The Lopez Canyon Landfill will have room for another 3 million tons of refuse in 1998. Normally, landfills take in an average of 1 million tons per year, but with recycling doing so well, it would take us five years to use up that remaining space. As an asset, the landfill would not be utilized to its full potential [if it were to close next year]. Financial aspects, as well as environmental, need to be considered."

Barbara Fine, vice chairwoman of the Solid Waste Citizens Advisory Group for Los Angeles

"It appears that an inclination toward landfilling has surfaced again. According to [Assembly Bill] 939, local agencies have to divert 50% of their refuse away from landfills by the year 2000. Our fear is that the waste management officials will eventually ask for a delay in those requirements when they find agencies unable to meet them. With more landfills open, less will be the incentive to recycle."

Bill Thompson, senior manager of public facilities at the South Coast Air Quality Management District

"Landfills are still the cheapest way to dispose of trash. There have been a number of stringent regulations applied to them in the recent past. Most landfills can produce electrical energy from their gas emissions. The Puente Hills Landfill produces enough to light a few thousand households. A similar proposal was made for Lopez Canyon. We're very supportive of that."

Jackson, who has pressed for other infrastructure improvements in Pacoima, one of the San Fernando Valley's most economically depressed communities.

ANGELES NATIONAL FOREST

Tiger Family Brought From Ireland Mends

A starved and abused family of Siberian tigers, brought from Ireland in December for rehabilitation at the Wildlife Waystation animal refuge in Angeles National Forest, have made a full recovery and will be released from quarantine into a new enclosure next Wednesday, way station officials said.

The female adult tiger began nursing her two cubs several weeks ago, and the male adult has improved dramatically since arriving Dec. 11, said way station founder Martine Colette.

The tigers were found at a farm in Ireland by Irish animal regulatory officials in December. Purchased from a circus in England by an individual who improperly cared for them, the tiger family originally included five cats, but one died before officials contacted the way station.

Animal welfare authorities first tried to place the severely malnourished tigers in zoos in Europe, but were unsuccessful.

When the tigers arrived at Los Angeles International Airport, Colette met them and feared the worst for the 7-year-old male, Batak, who was less than half his normal weight and appeared to be suffering from a stomach tumor. Way station veterinarians later examined Batak and determined the tumor was benign.

On Wednesday, Colette and her staff will move the furry foursome from their current quarters in the way station's quarantine area to a new 10,000-square-foot enclosure on a hill overlooking the main animal compound. The enclosure was built using donations from a way station sponsor who specified that the money could be spent only on new housing for tigers.

"We had literally just finished building the enclosure and pouring the concrete for the tiger pool when we heard these tigers in Ireland needed a home," said Diana Wenners, Colette's assistant. "It's amazing how it worked out."

The mother and the two cubs will enter the enclosure first, transported in crates carried by forklifts. The father will be introduced to the enclosure later in the day.

At the way station, the tigers have become part of one of the region's most remarkable and diverse collection of big cats. Cougars, bobcats, jaguars, panthers, tigers, lions and a tigress—a lion crossbred with a tiger—are among the way station's wards.

PANORAMA CITY

Rezoning Urged for New Housing Site

The Los Angeles Planning Commission will recommend that the City Council approve a zone change to allow higher-density housing on a 70,000-square-feet property in Panorama City.

The commission voted Thursday to recommend changing the designation of the property, at 9763 Vesper Ave., from one that would allow one home per lot and one unit per 7,500 square feet to one that allows multiple residences on each lot and one unit every 6,000 square feet.

If approved by the council, the zone change would allow 12 houses to be built on the irregularly shaped parcel south of Lassen Street. Eleven houses would be situated around a private cul-de-sac, while one would be constructed on Cedros Avenue, on which the property also has frontage.

An unusual feature of the development is that the lot will not be divided into individual plots. Instead, the yard space around the two story houses will be considered common areas, although each homeowner will have to maintain landscaping close to his or her home. Because of the lot's odd shape, property lines would have been difficult to draw between the homes, said Tom Henry, planning aide to Joel Wachs.

Henry said he heard few complaints about the project at a public hearing in December. The proposed zone "pretty much matches the density of property to the west and north."

The property is owned by Panorama City resident Helen Higashida. Two houses now on the site would be torn down to make way for the new homes, Henry said.

The project will probably go before the City Council's Planning and Land Use Management Committee within the next month and a half, and to the full council some time thereafter.

Henry said Wachs has not decided whether to support the project.

"To the south you have condominiums," Henry said. "To the north and west you have single-family homes. We want something that will be a nice buffer between the two, that will not have a negative impact, especially on the single-family homes."

SHERMAN OAKS

Gas Station Seeks Alcohol Sales Permit

A Los Angeles zoning official next week will consider an application by a businessman to sell beer and wine at a proposed mini-mart located at the intersection of Burbank and Sepulveda boulevards.

Valencia businessman Jack Khangura has applied for a conditional use permit to sell alcoholic beverages at a 24-hour market that he wants to add to his Shell station at 6556 Sepulveda Blvd.

"We have not yet taken a position" on the project, said Bonnie Kopp, an aide to City Councilman Marvin Braude. "We are talking to the police and trying to figure out what the impact on the community would be."

Kopp said she heard that a local homeowners association has expressed concerns about the proposed market, which would be open 24 hours a day, seven days a week.

Many community activists oppose the sale of alcohol at gas stations, fearful that it might encourage drinking and driving.

According to Khangura's application, there are now two liquor stores within the Shell station's so-called census tract, a designated area of residents surrounding it. The state Alcoholic Beverage Control Department allows six liquor licenses in a census tract, Khangura said.

The businessman said in his application that he would like to sell beer and wine coolers in single cans if he is allowed to do so by the city.

There are five parking spaces at the site.

The hearing will take place at 8:30 a.m. Feb. 24 at the Sherman Oaks Woman's Club, 4808 Kester Ave., in Sherman Oaks.

VAN NUYS

Alternatives to All-Year School Cited

Teachers opposed to converting Van Nuys High School to a year-round campus said Thursday that reducing enrollment or installing portable classrooms on nearby property would prevent the need to go year-round to relieve overcrowding.

Van Nuys is scheduled to enroll its first freshman class in 1998-99 under a districtwide plan to add ninth-graders to all high schools. To accommodate them, the school would probably have to host students year-round, rotating teenagers onto campus on staggered schedules.

But Charlie Wilken, one of several teachers opposed to a scheduling change, said he has come up with several proposals that would eliminate the need to operate on a year-round calendar.

One solution, said Wilken, the school's teachers union representative, would be for the Los Angeles Unified School District to make use of a piece of property that it owns several blocks away from the school.

"Next week, I'll be meeting with the district's people to talk about using the farm across the street from Valley Presbyterian Hospital and putting six bungalows on it," Wilken said.

He added that he would like to see those bungalows turned into an agricultural academy for Van Nuys students, but said the extra classroom space could at least relieve the overcrowding expected once ninth-graders are included.

Wilken will also suggest reducing the number of students at the high school by about 14%, a move that would force students at Van Nuys and its three specialized magnet programs to attend other schools.

One of those magnet programs is a joint medical studies program with Valley Presbyterian Hospital. Some teachers contend that the year-round system would hurt the three magnet programs by making it impossible for students to cross-register among them—currently one of the main attractions of the school.

But Joyce Peyton, director of the district's Office of School Utilization, said the district does not have the money to cover the $30,000 to $100,000 that each new bungalow would cost.

She also said that reducing the student population at Van Nuys would only overcrowd neighboring campuses such as Grant and Birmingham high schools.

"I don't know that we should be taking kids out of Van Nuys and putting them where that causes [problems] at another school," said Peyton, who is scheduled to meet with Wilken next week.

She added that the plot of land across from the hospital has already been reserved for an expansion of Van Nuys' medical studies program, which the district cannot afford at the moment.

Has Landfill at Lopez Canyon Had Its Fill?

By ANTONIO OLIVO
SPECIAL TO THE TIMES

Plans to close the Lopez Canyon Landfill in early 1996 may be postponed by the Los Angeles City Council if Bureau of Sanitation recommendations to continue operating the facility through the year 2000 are approved.

The bureau's suggestion came in response to a 1994 report that said the city could save $75 million by using the 20-year old facility another five years instead of adopting an alternative method of trash disposal next year.

The council had approved a similar five-year extension back in 1991 and had given the bureau until next February to shut the landfill.

Outraged community members responded to the possibility of yet another extension by pointing to language in a 1991 conditional use permit that promised a one-time-only renewal of operations at Lopez Canyon.

But bureau directors said that not only would the extension generate cash savings, but more time is needed to study alternative disposal programs.

They maintain that the facility is one of the best-run landfills in California, despite four citations in the last three months by the South Coast Air Quality Management District for gas emissions violations.

Situated in the hills just above Lake View Terrace, the landfill takes in about 80% of the city's household waste.

Should the Lopez Canyon Landfill be allowed to operate another five years?

Richard Alarcon, Los Angeles city councilman, 7th District

"We need to do a lot more to upgrade the system. By the year 2003, the life of this landfill will have expired. When that happens, we'll need to negotiate with another agency to dispose of our trash. If anything, we should leave space open to allow us room to negotiate with that agency."

LAKE VIEW TERRACE

Accident Calls Attention to Crumbling Hill

For years, Lake View Terrace and Pacoima residents say, they've asked that something be done about the steadily crumbling sandstone hill that towers over a 50-yard stretch of Osborne Street near Hansen Dam.

Rocks and dirt from the 100-foot-high embankment sometimes tumble onto the sidewalk and into the street, making passage difficult for pedestrians and cars going to and from Hansen Dam Recreation Area, a major outdoor attraction.

So when a rock recently rolled down the hill, bounced in the street and cracked the windshield of 68-year-old Marjorie Miller's passing car, residents said the time had come for the city to take action.

"I'm not concerned for me—I'm fine," said Miller of Lake View Terrace. "What I'm concerned about is the tremendous amount of liability the city is exposing itself to. To say they don't know is ridiculous, because they put [pylons] out to direct people around the debris.

"What I'm most concerned about is the young mothers who walk by that hill with babies," Miller said. "They are forced to push their strollers in the street because the sidewalk is covered with mud and rock. Can't the city just put up a fence or something?"

A spokesman for Councilman Richard Alarcon acknowledged that complaints have been made about the hill. The spokesman said field deputies will study the problem and possibly recommend action to the Department of Public Works.

Ray Jackson, president of the North East Valley Homeowners Assn., said he first requested action on the hill situation more than two years ago, when former Councilman Ernani Bernardi represented the district.

"They ignored us then," grumbled Jackson, who has pressed for other infrastructure improvements in Pacoima, one of the San Fernando Valley's most economically depressed communities.

—TIM MAY

RICHARD DERK / Los Angeles Times

Marjorie Miller stands on the sidewalk near rocks from the crumbling hill near Hansen Dam. Miller says the city should protect itself by making the area safe.

The enemy below L.A.

Landfills in Valley hold explosive, toxic threats

By TONY KNIGHT
Daily News Staff Writer

Escaping landfill gas, seeping toxic chemicals and the threat of contaminated wells have convinced city officials it was a mistake — one that may never be corrected — to cluster eight garbage dumps in the North Hollywood-Sun Valley area.

At least twice in the last five years, methane gas, a byproduct of decomposing trash, has reached explosive levels at schoolyards in the East Valley landfill area, long the primary garbage dumping ground for the city of Los Angeles.

Traces of toxic chemicals, some known to cause cancer, are being found in gas at most of the landfills, where only non-toxic refuse was supposed to be buried.

Water quality officials suspect that toxic solvents at the landfills are leaching through the sandy soil and adding to the Valley's already serious groundwater pollution problem.

In extensive interviews and checks of city, county and state

Please see LANDFILL Pg. 16

EXH. 77

from page 1

Landfill errors of the past pose today's toxic threats

LANDFILL from Pg. 1

records, the Daily News found a lack of coordination among various government agencies that have authority over the dumps and evidence that past efforts to lessen the environmental threats have fallen short.

Despite the environmental problems, plans for two more dumps have been approved in the area by the city Bureau of Sanitation. State officials are blocking their operation because of the threat of more groundwater pollution.

Indeed, with the city generating 35,000 tons of garbage a day, dumpsites are becoming harder to find.

"I think it's a crisis," said Del Biagi, director of the Bureau of Sanitation. "The people in the city say, 'Take it to the desert,' and the people in the desert say, 'You generated it, you eat it.'"

Sanitation officials said the new dumps will be lined with impervious clay barriers and equipped with modern gas control systems. Strengthened state and federal regulations will prevent further environmental damage, they believe.

But such protections have not eased the concern of Councilman Howard Finn, whose First District gets 80 percent of the city's garbage.

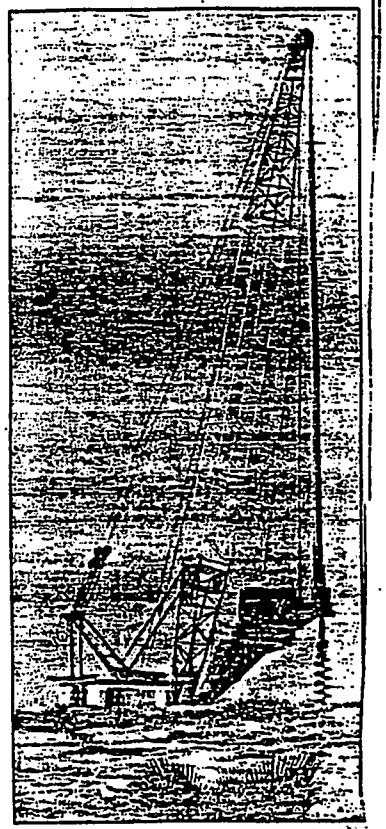
"They really have no control over what's been dumped in those landfills — that's the problem," Finn said.

"They say, 'If we knew 20 years ago what we know now, you wouldn't have all these problems.' I'm saying that's the same thing they're going to say 20 years from now."

Even if past mistakes are avoided, serious problems remain from refuse dumped over the last 50 years at landfills clustered in a 1.5-mile radius in the North Hollywood-Sun Valley area.

More than 50 million cubic yards of garbage — enough to cover five football fields to a height of one mile — have been buried in the area since the 1930s. Most of the landfills reached capacity and closed in the 1970s.

The dumps are the legacy of sand mining operations that left yawning pits in the area. The city's plan was to fill those eyesores with garbage.



"At that time it seemed like the logical thing to do," said Sterling Buesch, assistant director of the Bureau of Sanitation. "They didn't know about the gas problems associated with landfills."

Air quality records show decomposing trash at the landfills produce more than 15 million cubic feet of gas daily — enough to supply 200 single-family homes with gas for a year.

Sanitation officials said the area's gas problems have been controlled by collection systems which channel the gas to a flare where it is burned off.

However, records show L.A. By-Products' Tuxford Pit still has no collection system. Gas migrating from the site reached explosive levels in 1982, and migrating gas was measured there as late as last week.

The gas collection system at the city-owned Sheldon-Arleta Landfill wasn't installed until 1978, three years after the dump closed.

Scott Garrey / Daily News

Drilling rig is used to check for possible problems at Penrose Landfill near Arminta Street school.

In 1980, gas migrating about 900 feet from the landfill forced the evacuation of gyms at nearby John H. Francis Polytechnic High School for four months. Migrating gas set off alarms at the school March 28. The boy's gym was evacuated for a day.

"Significant" levels of toxic compounds have been measured in landfill gas at the Penrose Landfill, across the street from Arminta Street Elemen-

LANDFILL from Pg. 16

tary School. The dump was in violation of gas control regulations in 1980 and 1983.

"If we knew what we know now, we wouldn't have done it. Or we would have done it differently," said Robert Alpern, principal civil engineer for the city Bureau of Sanitation. "The intent was that there were all these pits, and the people wanted them filled in, and there wasn't anything else to put in it."

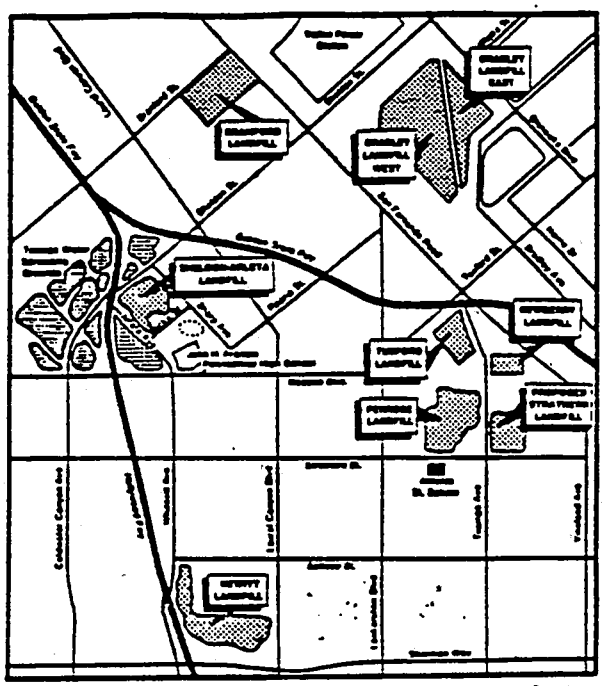
Officials shudder at the prospect of digging up the landfills because of the odor and cost of such operations.

"We're going to live with them unless we excavate them — and I don't think that's going to happen," said Hank Yacoub, supervising engineer for the Los Angeles Regional Water Quality Control Board. "With today's knowledge, instruments, and standards, you wouldn't have seen that many landfills in that area."

Originally, the dumps were regulated by the city Bureau of Street Maintenance and the regional water quality board. The state's Solid Waste Management Board wasn't in existence until 1976. Federal laws regulating landfills weren't passed until 1978.

"I think it is no secret that although those landfills operated as trash-only facilities, it appears hazardous materials made their way in with the trash," said Yacoub of the water quality board.

"The regulations were nothing near as stringent as they are today," said John L. Lewis, the water quality board's enforcement officer. "Plus, there was little or no enforcement of the regulations at that time."



Toxic levels in the landfill gas are so low they would be harmless once the gas is diluted in the open air, sanitation officials said.

Health officials agreed people near the landfills are not in imminent danger, but they said there is no way of knowing the long-term risks of exposure to low levels of cancer-causing compounds.

"What it gets down to is what is an exposable risk based on proximity to the landfill," said Dr. James Stratton, a state health department epidemiologist who is conducting a study to determine health effects on residents near the BKK landfill in West Covina.

Long-time teachers at Poly High and Armuta Street School are worried about the health effects of working across the street from the dumps. Many teachers have worked at the schools for more than 20 years.

LOCATION OF NORTHEAST VALLEY LANDFILLS

Daily News

In retrospect, Los Angeles city officials say it was a mistake to cluster eight garbage dumps in North Hollywood-Sun Valley area.

A TOXIC LEGACY

- Gyms at John H. Francis Polytechnic High School were closed for four months in 1980 after health officials measured explosive levels of methane coming from the city-owned Sheldon-Arleta Landfill, 12455 Wicks St. Gas collection system failed because of corrosion of pipes and was redesigned completely. Gas monitor alarms went off in 1983, requiring enlargement of the collection system.
- Sheldon-Arleta closed in 1975, but a gas migration system was not installed until 1978. Traces of benzine have been measured in the landfill gas.
- Significant levels of toxic chemicals were measured in landfill gas at the Penrose Landfill, 8251 Tujunga Ave., across the street from Armuta Street Elementary School. In 1983, teachers complained that odors from the landfill were making children sick. The landfill was in violation of gas migration regulations in 1980 and 1983, state officials said.
- In 1982, explosive levels of methane gas were measured coming from the Toxford Pit, 8501 Tujunga Ave. State officials say the city Bureau of Sanitation was supposed to require installation of a gas control system, but this never happened.
- The Sheldon-Arleta Landfill shares a common well with the city's Tujunga Spreading Grounds, where mountain runoff percolates into groundwater. A clay liner was placed between the trash and the drinking water, but officials doubt whether it is working properly.
- Operation of Hansen Dam Spreading Grounds was halted in 1981 when rising groundwater came within 10 feet of the bottom of the Bradley East Landfill, 11629 Wicks St., nearly causing a major environmental problem. The Hansen Dam water was released to the Los Angeles River and "wasted" to the ocean.
- Toxic solvents measured in wells near the Penrose Landfill and the Hewitt Landfill, 7245 Laurel Canyon Blvd. Officials say the dumps are probably one source of the Valley's groundwater contamination problem.

"We think we've had a lot of cancer," said Sylvia Brown, a Poly High counselor. "One of the teachers gets headaches all the time. The P.E. teachers feel there is something."

In 1980, teachers at Poly High complained that mysterious fumes were seeping into the locker rooms. A county health official said the cause was dirty sweat socks.

When teachers complained of burning eyes and headaches, investigators checked again and found explosive levels of methane gas in the locker rooms and in the school auditorium. They traced the fumes to Sheldon-Arleta.

A year later, Harvey Noels, an assistant principal and part-time coach, died of liver cancer, triggering a wave of concern among faculty members. A committee was formed and is trying to determine the chemical composition of gas generated at the dump site.

Air quality records show the landfill gas contains traces of benzine, a known carcinogen. However, no links have been made between Noels' death and the landfill gas.

Jack Waldron, district health and safety officer, said the toxic traces were insignificant and the landfill no longer poses a health risk.

A 1983 school district survey at Arminta Street school, near the Penrose Landfill, indicated 96 percent of the teachers "report adverse health effects associated with the dump site." The same year a teacher told a water quality inspector about strong odors and that, "kids get sick often due to the landfill."

In 1982, measurements of concentrated landfill gas at Penrose revealed the presence of such suspected carcinogens as benzine (20,000 parts per billion), trichloroethylene (1,300 parts per billion), and vinyl chloride (4,500 parts per billion.)

"What that demonstrates is that there are significant levels of carcinogenic gases in the landfill gas," said Robert Stevens, chief of the state Department of Health's hazardous materials lab. "The fact that they are flaring it is good, because it isn't escaping into the neighborhood."

The state safety standard for vinyl chloride in the open air is 10 parts per billion; there are no known standards for safe open air concentrations of TCE or benzine. All three compounds would dilute quickly in the open air.

The Penrose Landfill was in violation of gas migration regulations in 1980 and 1983, said John Bell, manager of the Solid Waste Management Board's monitoring section. Sanitation officials said the problem has been corrected. State officials, checking the site last week for the first time in four years, found two methane probes clogged and inoperable.

Arminta teachers still complain of frequent headaches. "When I walk into my room, I can smell it from the night before," said Ada Bender, a fifth-grade teacher.

Richard Salisbury, president of L.A. By-Products, operators of the Penrose Landfill, said toxic volumes in the dump are too small to be dangerous. "Those contaminants are found all over the Valley," Salisbury said. "I think everybody is trying to point the finger at landfill operators when there are other sources of contamination."

L.A. By-Products operated the Tuxford Pit until 1973 when it was sold to Adlen Brothers Auto Wreckers.

In 1982 state officials measured explosive levels of methane migrating underground from the site. The Bureau of Sanitation was supposed to force installation of a gas control system, said Mary Coyle, an enforcement officer with the state Solid Waste Management Board.

It never happened.

"I think it was pointed out that under existing law we didn't have authority to require compliance," said Buesch, the assistant sanitation director.

"We are in the process now of showing them that they are the enforcing party ... the responsible agency," said John Bell, of the waste management board.

Water officials said the primary sources of well contamination are undergorund industrial tanks and "backyard" commercial dumping with landfills a likely secondary source.

"The landfills may be a contributor, and we suspect that they are," said Mel Blevins, the Department of Water and Power's senior hydrologic engineer. "But they're not the major contributor."

Recent tests show 40 percent of the Valley wells are contaminated with traces of TCE and perchloroethlyene (PCE), carcinogenic industrial solvents. Health officials have closed 13 of the 109 Valley wells. Forty others are tainted but can be used if the water is blended with untainted water.

The state's safety standard for TCE in drinking water is 5 parts per billion. The standard for PCE is 4 ppb. TCE has been measured at 31 ppb in a well downsteam from Penrose. PCE has been measured at 3.9 ppb downstream from Valley Reclamation Inc.'s Hewitt Landfill.

"What that means is that the existing landfills have leached some of this material into the groundwater," Blevins said. "That's not a lot, but it's enough to say, 'Well, what's happening there.'"

State regulations now require an impervious clay liner on the bottom and sides of landfills. Previously, the only regulation was that the bottom of the trash heap be 10 feet above the historical high water mark.

"That's an antiquated standard," Yacoub said. "The gas can travel in any direction."

Officials hope the monitoring program will determine if water from the spreading grounds has inundated trash at the Bradley East and Sheldon-Arleta landfills.

No. 375, Docket 91-7450.

United States Court of Appeals, Second Circuit.

Argued Oct. 2, 1991.

Decided March 12, 1992.

Action was brought against owners and operators of landfill to recover past and future cleanup costs under CERCLA. Landfill owner filed third-party actions for contribution and indemnification from municipalities. Complaints were amended to add municipalities as defendants in the original action. Motions of the municipalities for summary judgment was denied by the United States District Court for the District of Connecticut, Peter C. Dorsey, J., 754 F.Supp. 960, and municipalities appealed. The Court of Appeals, Cardamone, Circuit Judge, held that CERCLA imposes liability on municipality which arranges for disposal or treatment of municipal solid waste that contains primarily household waste.

Affirmed.

1. Health and Environment ⇐25.5(5.5)

CERCLA imposes strict liability. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, § 107, as amended, 42 U.S.C.A. § 9607.

2. Health and Environment ⇐25.5(5.5)

Where environmental harm is indivisible, liability under CERCLA is joint and several. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, § 107, as amended, 42 U.S.C.A. § 9607.

3. Health and Environment ⇐25.5(5.5)

Broad reach of CERCLA extends liability to all those contributing, from generation through disposal, to problems caused by hazardous substances. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, § 107, as amended, 42 U.S.C.A. § 9607.

4. Health and Environment ⇐25.5(5.5)

Because it is a remedial statute, CERCLA must be construed liberally to effectuate its two primary goals of enabling the Environmental Protection Agency (EPA) to respond efficiently and expeditiously to toxic spills and holding those parties responsible for releases liable for the costs of the cleanup. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, § 107, as amended, 42 U.S.C.A. § 9607.

5. Health and Environment ⇐25.5(5.5)

Liability under CERCLA is precluded only by defense that the release or threatened release was caused solely by an act of God, an act of war, or certain acts or omissions of third parties other than those with whom defendant had a contractual relationship. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, § 107, as amended, 42 U.S.C.A. § 9607.

6. Health and Environment ⇐25.5(5.5)

Prima facie cause of action under CERCLA requires that plaintiff establish that defendant fits one of the four classes of responsible parties outlined in the statute, that the site is a facility, that there is a release or threatened release of hazardous substances at the facility, that the plaintiff incurred costs in responding to the release or threatened release, and that the costs and response actions conform to the National Contingency Plan. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, § 107, as amended, 42 U.S.C.A. § 9607.

7. Health and Environment ⇐25.5(5.5)

Municipality may be liable for response costs under CERCLA as a potentially responsible party if it arranges for the disposal of hazardous substances. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, § 107, as amended, 42 U.S.C.A. § 9607.

8. Health and Environment ⇐25.5(5.5)

Liability under CERCLA as an arranger requires sufficient nexus between municipality and hazardous substances, one that does not exist in cases where the governmental unit is responsible only for promulgating disposal regulations or for permitting disposal facilities. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, § 107, as amended, 42 U.S.C.A. § 9607.

9. Health and Environment ⇐25.5(5.5)

CERCLA does not provide exemption from municipalities arranging for disposal of municipal solid waste that contains hazardous substances simply because the municipality undertakes that action in furtherance of its sovereign status. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, § 107, as amended, 42 U.S.C.A. § 9607.

10. Health and Environment ⇐25.5(5.5)

Substance need only be designated as hazardous under any one of the four environmental statutes or under EPA table in order to be a hazardous substance under CERCLA; CERCLA does not require substance to be delineated as hazardous under more than one of the subsections. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, §§ 101(14), 102, as amended, 42 U.S.C.A. §§ 9601(14), 9602.

11. Health and Environment ⇐25.5(5.5)

CERCLA does not make any distinction either among potentially responsible parties or by virtue of source of hazardous substance; whether potentially responsible party is owner or operator of facility, arranger, generator, or transporter of hazardous substance, or is a municipality, individual, or chemical manufacturing company, is not relevant in determining whether substance is hazardous. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, §§ 101(14), 102, as amended, 42 U.S.C.A. §§ 9601(14), 9602.

12. Health and Environment ⇐25.5(5.5)

CERCLA's definition of hazardous substance makes no distinction dependent upon whether the substance's source was industrial, commercial, municipal, or household, and whether the substance is a consumer product, manufacturing by-product, or element of waste stream is irrelevant. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, §§ 101(14), 102, as amended, 42 U.S.C.A. §§ 9601(14), 9602.

13. Health and Environment ⇐25.5(5.5)

Quantity or concentration is not a factor in determining whether a substance is hazardous for purposes of CERCLA. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, §§ 101(14), 102, as amended, 42 U.S.C.A. §§ 9601(14), 9602.

14. Health and Environment ⇐25.5(5.5)

Concentration of hazardous substances in municipal solid waste, regardless of how low a percentage, is not relevant in deciding whether CERCLA liability is incurred. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, §§ 101(14), 102, 107, as amended, 42 U.S.C.A. §§ 9601(14), 9602, 9607.

15. Health and Environment ⇐25.5(5.5)

Silence of CERCLA on the subject of municipal solid waste is not evidence that municipal solid waste should be excluded from definition of hazardous substances. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, §§ 101(14), 102, as amended, 42 U.S.C.A. §§ 9601(14), 9602.

16. Health and Environment ⇐25.5(5.5)

When mixture of waste solution contains hazardous substances, that mixture is itself hazardous for purposes of determining CERCLA liability. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, §§ 101(14), 102, 107, as amended, 42 U.S.C.A. §§ 9601(14), 9602, 9607.

17. Contribution ⇐5(6)

Health and Environment ⇐25.5(5.5)

If municipality arranges for disposal or treatment of waste containing substances listed as hazardous in any of four environment statutes or the EPA table, it may be held liable for contribution or response costs under CERCLA if subsequent release or threatened release requires cleanup efforts. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, §§ 101(14), 102, 107, as amended, 42 U.S.C.A. §§ 9601(14), 9602, 9607.

18. Health and Environment ⇐25.5(5.5)

Exemptions for household waste, promulgated by Environmental Protection Agency (EPA) and subsequently confirmed in part by Congress, from certain regulatory requirements under the Resource Conservation and Recovery Act (RCRA) does not extend through incorporation by reference to the definition of hazardous substance under CERCLA. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, §§ 101(14), 102, as amended, 42 U.S.C.A. 9601(14), 9602; Solid Waste Disposal Act, § 1002 et seq., as amended, 42 U.S.C.A. § 6901 et seq.

19. Health and Environment ⇐25.5(5.5)

Resource Conservation and Recovery Act (RCRA) is designed primarily to regulate on-going treatment, storage, and disposal of solid and hazardous waste. Solid Waste Disposal Act, § 1002 et seq., as amended, 42 U.S.C.A. § 6901 et seq.

20. Health and Environment ⇐25.5(5.5)

Congress and the Environmental Protection Agency (EPA) carefully distinguished between wastes, to which the Resource Conservation and Recovery Act (RCRA), applies, and substances, to which CERCLA applies. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, §§ 101(14), 102, as amended, 42 U.S.C.A. §§ 9601(14), 9602.

21. Health and Environment ⇐25.5(5.5)

Application of Resource Conservation and Recovery Act's (RCRA) regulations turns in part upon threshold quantity or concentration requirements, considerations which are irrelevant in finding hazardous substances under CERCLA. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, §§ 101(14), 102, as amended, 42 U.S.C.A. §§ 9601(14), 9602.

22. Health and Environment ⇐25.5(5.5)

Subpart C regulations under the Resource Conservation and Recovery Act (RCRA) impose tough standards for operating active toxic waste sites, but do not cover sites operated prior to its enactment, nor sites where the owner is unknown or bankrupt, nor does it address spills, illegal dumping, or releases generally; RCRA is preventative, and CERCLA is curative. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, §§ 101(14), 102, as amended, 42 U.S.C.A. §§ 9601(14), 9602.

23. Health and Environment ⇐25.5(5.5)

Where substance is not exempted from definition of hazardous substance set forth in CERCLA, but merely is exempted from regulation under a separate statute, that exemption will not be incorporated into the definition of hazardous substance under CERCLA. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, § 101(14), as amended, 42 U.S.C.A. 9601(14).

24. Health and Environment ⇐25.5(5.5)

Environmental Protection Agency's (EPA's) exemption of household wastes from notification requirements under CERCLA does not suggest that disparate treatment of municipal solid waste under the Act's liability provisions is appropriate. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, §§ 101(14), 103(c), 107, as amended, 42 U.S.C.A. §§ 9601(14), 9603(c), 9607.

25. Statutes ⇐219(6)

Court should defer to Environmental Protection Agency's (EPA's) reasonable construction of CERCLA absent clearly expressed contrary congressional purpose; to be accorded deference, EPA's construction of CERCLA need not be one that the court would have chosen, nor the only reasonable one permitted by the Act's language. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, § 101 et seq., as amended, 42 U.S.C.A. § 9601 et seq.

26. Health and Environment ⇐25.5(5.5)

Amount of liability imposed upon municipality for response costs under CERCLA will not necessarily be a function solely of the total volume of municipal waste disposed of in the landfill but, rather, will be a function of the extent to which municipal dumping of hazardous substances both engendered the necessity and contributed to the costs of cleanup. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, § 113(f)(1), as amended, 42 U.S.C.A. § 9613(f)(1).

Before CARDAMONE, WALKER and McLAUGHLIN, Circuit Judges.

CARDAMONE, Circuit Judge:

This appeal deals with the disposal of municipal solid waste that contains hazardous substances and as such is one piece of the national environmental problem. The problem is precipitated by the presence of over 200 municipal landfills, comprising about 20 percent of the more than 1,000 sites, that pose sufficient environmental concerns to warrant priority in federal cleanup efforts. *See generally* Interim Municipal Settlement Policy, 54 Fed.Reg. 51,071 (1989). Whether, when, and at what cost this environmental muddle will be resolved is unknown; but to maintain Congress' comprehensive statutory chain of responsibility it is essential that one step at a time be taken.

To take that step on this appeal we must carefully analyze the Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (CERCLA or Act), 42 U.S.C. § 9601, *et seq.*, as amended by the Superfund Amendments and Reauthorization Act of 1986 (Superfund Amendments), Pub.L. No. 99-499, 100 Stat. 1613 *et seq.*, and while remaining aware of the interaction of CERCLA with other federal environmental statutes—in this case primarily the Resource Conservation and Recovery Act (Resource and Recovery Act or RCRA), 42 U.S.C. § 6901, *et seq.*—determine what CERCLA defines as hazardous substances, and whether CERCLA imposes liability on a municipality which arranges for the disposal or treatment of municipal solid waste that contains primarily household waste.

BACKGROUND

At the center of this litigation lie the Beacon Heights and Laurel Park landfills, both located in Connecticut, designated as Superfund sites on a National Priority List by the Environmental Protection Agency (EPA). Four actions, now consolidated, were commenced separately in 1987 by the EPA, the State of Connecticut Department of Environmental Protection, Uniroyal Chemical Company, Inc., and a coalition of corporations led by B.F. Goodrich Company (collectively, plaintiffs). Plaintiffs sought reimbursement for past and future cleanup costs from the owners or operators of the landfills, including Terrence and Harold Murtha and their several corporations (collectively, Murtha).

In turn, Murtha commenced third-party actions seeking contribution or indemnification and other statutory and common law relief against approximately 200 third-party defendants. Among the third-party defendants are the Connecticut municipal appellants. They include the cities and/or towns of Ansonia, Beacon Falls, Bethany, Hamden, Killingworth, Middlebury, Milford, New Haven, Orange, Plymouth, Seymour, Shelton, Stamford, Stratford, Thomaston, Waterbury, Watertown, Westport, Woodbury, the borough of Naugatuck, the Housing Authorities of New Haven and Watertown, and the Connecticut Resources Recovery Authority.

In 1988 the district court permitted plaintiffs to amend their complaints and add the third-party defendants as defendants in the original action. Fundamental to both the original and the third-party actions are the allegations that the municipal defendants arranged for the disposal and/or treatment of hazardous substances at the two landfills and are therefore subject to liability under § 9607 of CERCLA for a share of past and future cleanup costs, now estimated to exceed $47.9 million.

After serving answers denying liability, the municipal defendants as a group moved for summary judgment arguing that, as a matter of law, their generation and collection of municipal solid waste did not subject them to liability under CERCLA. The United States District Court for the District of Connecticut (Dorsey, J.) denied this motion in a judgment dated January 8, 1991. *B.F. Goodrich Co. v. Murtha*, 764 F.Supp. 960 (D.Conn.1991). It held that CERCLA does not contain any exemption for municipal waste, and that the exclusion for household solid waste found in the Resource and Recovery Act is not incorporated into the CERCLA definition of hazardous substances. It held further that a municipality disposing of hazardous substances at a site where there is a release or threatened release of such substances may be liable under § 9607 and that plaintiffs had raised genuine issues of material fact as to whether the municipal defendants' waste contained hazardous substances covered by CERCLA. The municipalities appeal from the judgment denying them summary judgment. We affirm.

DISCUSSION

The focus of our inquiry is the question of municipal liability under CERCLA for arranging for the disposal or treatment of municipal solid waste. Procedurally, we review a denial of appellants' motion for summary judgment; summary judgment may appropriately be granted only if the record demonstrates that there is no genuine issue as to any material fact and that the movant is entitled to a judgment as a matter of law. Fed.R.Civ.P.Rule 56(c); *Celotex Corp. v. Catrett*, 477 U.S. 317, 330, 106 S.Ct. 2548, 2556, 91 L.Ed.2d 265 (1986) (Brennan, J., dissenting). Appellants do not seriously dispute the district court's finding that genuine issues of material fact exist, *i.e.*, that plaintiffs raised a genuine issue, unrefuted by the municipalities, as to the existence of CERCLA-defined hazardous substances in the municipalities' solid waste. *See* 764 F.Supp. at 968-72. Rather the municipal defendants argue that CERCLA provides plaintiffs no grounds for relief and, as a result, the municipalities are entitled to judgment as a matter of law.

At the center of our discussion is the subject of municipal solid waste which, while possibly containing material from commercial and industrial sources, is primarily composed of household waste. *See* 54 Fed.Reg. at 51,075. Despite the tremendous volume of household waste, surveys generally reveal that it contains very low concentrations—less than 1 percent by weight—of substances the EPA considers hazardous to the environment or to public health. *See* Ferrey, *The Toxic Time Bomb: Municipal Liability for the Cleanup of Hazardous Waste*, 57 Geo.Wash.L.Rev. 197, 200-10 (1988). Yet, even though household waste has a low concentration of hazardous substances, when the EPA determines that a cleanup under CERCLA is warranted the costs of cleanup at municipal landfills may be greater than at similar industrial or commercial toxic waste sites due to household waste's greater volume and reduced toxicity. With this in mind, we turn to the statutory framework.

I *Statutory Framework Under CERCLA*

In CERCLA Congress enacted a broad remedial statute designed to enhance the authority of the EPA to respond effectively and promptly to toxic pollutant spills that threatened the environment and human health. The EPA is authorized to commence "response actions" to abate any actual or threatened releases of hazardous substances, § 9604(a)(1), and a federal Superfund exists to pay for mandated cleanups. Response actions include remedial efforts to prevent or minimize releases as well as attempts to remove hazardous substances entirely. The Act also authorizes the EPA to recover its costs from responsible parties as a means to replenish and maintain the Superfund. *See* § 9607(a)(4)(A). Alternatively, the EPA may seek to compel potentially responsible parties to commence private response actions if there is an "imminent and substantial endangerment to the public health." § 9606(a). Such parties may recover a por-

tion of their response costs from other potentially responsible parties. § 9613(f).

[1-3] CERCLA imposes strict liability. *See Tanglewood East Homeowners v. Charles-Thomas, Inc.*, 849 F.2d 1568, 1572 (5th Cir.1988); *State of New York v. Shore Realty Corp.*, 759 F.2d 1032, 1042 (2d Cir. 1985). Where the environmental harm is indivisible liability is joint and several. *See O'Neil v. Picillo*, 883 F.2d 176, 178-79 (1st Cir.1989), *cert. denied sub nom. American Cyanamid Co. v. O'Neil*, 493 U.S. 1071, 110 S.Ct. 1115, 107 L.Ed.2d 1022 (1990); *United States v. R.W. Meyer, Inc.*, 889 F.2d 1497, 1506-08 (6th Cir.1989), *cert. denied*, 494 U.S. 1057, 110 S.Ct. 1527, 108 L.Ed.2d 767 (1990). CERCLA establishes four classes of responsible parties liable for the costs of responding to releases or threatened releases of hazardous substances. These include past and present owners or operators of facilities, transporters of hazardous substances, and those, such as appellants, who generate or arrange for the disposal or treatment of hazardous substances. § 9607(a). The Act's broad reach extends liability to all those contributing to—from generation through disposal—the problems caused by hazardous substances.

[4, 5] Because it is a remedial statute, CERCLA must be construed liberally to effectuate its two primary goals: (1) enabling the EPA to respond efficiently and expeditiously to toxic spills, and (2) holding those parties responsible for the releases liable for the costs of the cleanup. In that way Congress envisioned the EPA's costs would be recouped, the Superfund preserved, and the taxpayers not required to shoulder the financial burden of a nationwide cleanup. *See United States v. Aceto Agric. Chems. Corp.*, 872 F.2d 1373, 1377, 1380 (8th Cir.1989) (quoting *Dedham Water Co. v. Cumberland Farms Dairy, Inc.*, 805 F.2d 1074, 1081 (1st Cir.1986)); *City of New York v. Exxon Corp.*, 744 F.Supp. 474, 485 (S.D.N.Y.1990). Potential affirmative defenses are limited to those listed in § 9607(b). *See Shore Realty*, 759 F.2d at 1048-49; *United States v. Hooker Chems. & Plastics Corp.*, 680 F.Supp. 546, 557-58 (W.D.N.Y.1988). Hence, liability under § 9607(a) is precluded only by a defense that the release or threatened release was caused solely by an act of God, an act of war, or certain acts or omissions of third parties other than those with whom a defendant has a contractual relationship. *See* § 9607(b). Undeterred by the inapplicability of any of these affirmative defenses to the present case, appellants insist that a municipality may not be held liable under CERCLA, § 9607(a)(3), for arranging for the disposal or treatment of municipal solid waste because that waste is not defined as a hazardous substance under the Act.

[6] A *prima facie* cause of action under CERCLA requires a plaintiff to establish: (1) defendant fits one of the four classes of responsible parties outlined in § 9607(a); (2) the site is a facility; (3) there is a release or threatened release of hazardous substances at the facility; (4) the plaintiff incurred costs responding to the release or threatened release; and (5) the costs and response actions conform to the National Contingency Plan set up under the Act and administered by the EPA in order to prioritize hazardous substance release sites throughout the nation. *See Shore Realty*, 759 F.2d at 1043. The municipalities' summary judgment motion turns on whether their arranging for the disposal of municipal solid waste satisfies the first and third elements.

II *Responsible Party*

[7] As to the first element, it is clear that a municipality may be liable as a potentially responsible party if it arranges for the disposal of hazardous substances. CERCLA expressly includes municipalities, states, and other political subdivisions within its definition of persons who can incur such liability under § 9607. § 9601(21). The Supreme Court has held that the "cascade of plain language" clearly demonstrates Congress aimed to abrogate sovereign immunity for the states. *Pennsylvania v. Union Gas Co.*, 491 U.S. 1, 7-13, 109 S.Ct. 2273, 2277-80, 105 L.Ed.2d 1 (1989). As further evidence of Congress' plan that municipalities be held as responsible parties, CERCLA includes limited exceptions to potential municipal liability. Where, as an "owner or operator," a municipality acquires ownership or control of a facility involuntarily as a result of its sovereign function, § 9601(20)(D), or where a municipality acts in response to an emergency caused by the release of hazardous substances from a facility owned by another party and does not act with gross negligence or willful misconduct, § 9607(d)(2), no liability attaches. These express exceptions to liability are strong evidence that municipalities are otherwise subject to CERCLA liability.

In the face of CERCLA's unambiguous scheme concerning municipal liability and the limited exceptions to it, appellants cite *Lincoln v. Republic Ecology Corp.*, 765 F.Supp. 633 (C.D.Cal.1991), apparently for the proposition that liability cannot attach to a municipality that arranges for the disposal or treatment of hazardous substances in its sovereign capacity. We regard *Lincoln* as merely holding that the city's activities in that case, taken in furtherance of its sovereign function to abate public nuisances, were insufficient to give rise to "arranger" status for purposes of liability under CERCLA. *See id.* at 636-38. To the extent *Lincoln* can be construed as extending the "function as a sovereign" exception beyond the liability provision for owners or operators to that for arrangers, we disagree with it. *Cf. Union Gas*, 491 U.S. at 12-13, 109 S.Ct. at 2280 (§ 9601(20)(D) qualifies entire definition of "owner or operator," not merely the portion thereof applicable to involuntary owners). Congress limited the sovereign function exception to those situations where liability is premised on the state or local government entity being an "owner or operator" of a vessel or facility. *See* § 9601(20). Nothing in the language of the Act suggests that it be extended.

[8, 9] We recognize that liability under the arranger subsection requires a sufficient nexus be present between the municipality and the hazardous substances, one that does not exist in cases where the governmental unit is responsible only for promulgating disposal regulations or for permitting disposal facilities. *See United States v. New Castle County*, 727 F.Supp. 854, 872-74 (D.Del.1989); *State of New York v. City of Johnstown, N.Y.*, 701 F.Supp. 33, 36 (N.D.N.Y.1988). Nonetheless, once a sufficient nexus is established (such as, in this case, by managing the disposal activities), the reasons prompting the establishment of that nexus are of no consequence. To construe CERCLA as providing an exemption for municipalities arranging for the disposal of municipal solid waste that contains hazardous substances simply because the municipality undertakes such action in furtherance of its sovereign status would create an unwarranted break in the statutory chain of responsibility.

III *Hazardous Substance*

A. CERCLA Definition

Since release or threatened release is not here at issue, discussion of the third element—which is the principal subject of this opinion—turns to whether municipal solid waste falls within CERCLA's definition of hazardous substance. We start by reviewing the language of the Act itself, *United States v. James*, 478 U.S. 597, 604, 106 S.Ct. 3116, 3120, 92 L.Ed.2d 483 (1986), and assume the ordinary meaning of the language used expresses Congress' purpose. *American Tobacco Co. v. Patterson*, 456 U.S. 63, 68, 102 S.Ct. 1534, 1537, 71 L.Ed.2d 748 (1982). Unless a clearly expressed legislative aim to the contrary is found, that meaning controls. *Consumer Product Safety Commission v. GTE Sylvania, Inc.*, 447 U.S. 102, 108, 100 S.Ct. 2051, 2056, 64 L.Ed.2d 766 (1980).

[10] CERCLA defines as hazardous any substance so designated by the EPA pursuant to § 9602 or by any of four other environmental statutes. Section 9601(14) states

> The term "hazardous substance" means (A) any substance designated pursuant to section 1321(b)(2)(A) of Title 33, (B) any element, compound, mixture, solution, or substance designated pursuant to section 9602 of this title, (C) any haz-

ardous waste having the characteristics identified under or listed pursuant to section 3001 of the Solid Waste Disposal Act ..., (D) any toxic pollutant listed under section 1317(a) of title 33, (E) any hazardous air pollutant listed under section 112 of the Clean Air Act ..., and (F) any imminently hazardous chemical substance or mixture with respect to which the Administrator has taken action pursuant to section 2606 of title 15. The term does not include petroleum, including crude oil or any fraction thereof which is not otherwise specifically listed or designated as a hazardous substance under subparagraphs (A) through (F) of this paragraph, and the term does not include natural gas, natural gas liquids, liquefied natural gas, or synthetic gas usable for fuel (or mixtures of natural gas and such synthetic gas).

Pursuant to subsection (B) above and under § 9602, the EPA has listed over 700 hazardous substances in Table 302.4 of 40 C.F.R. § 302. The Act's definition of hazardous substance covers a vast array. A substance need only be designated as hazardous under any *one* of the four environmental statutes or under Table 302.4 to be a hazardous substance under CERCLA. Courts uniformly have found that the Act does not require a substance to be delineated as hazardous under more than one of the subsections to be so viewed. *See, e.g., Eagle-Picher Industries, Inc. v. United States EPA*, 759 F.2d 922, 927 (D.C.Cir. 1985); *United States v. Carolawn Co.*, 21 E.R.C. 2124, 2125 (D.S.C.1984); *United States v. Metate Asbestos Corp.*, 584 F.Supp. 1143, 1146 (D.Ariz.1984).

[11] Other features of § 9601(14) demonstrate its breadth. For example, though Congress specifically excluded from the definition of hazardous substance two substances—natural gas and oil—no other exclusions are found. Nor is any distinction made either among potentially responsible parties or by virtue of the source of the hazardous substances. Whether a potentially responsible party is an owner or operator of a facility, or an arranger, generator or transporter of the hazardous substance, or a municipality, individual or chemical manufacturing company is not relevant in determining whether a substance is hazardous. Where Congress differentiated based on a potentially responsible party's status, it did so directly through specific exemptions such as those for municipalities that acquire title to facilities involuntarily or that act in response to emergencies. *See* §§ 9601(20)(D), 9607(d)(2).

[12-14] Similarly, the definition makes no distinction dependent upon whether the substance's source was industrial, commercial, municipal or household. Whether the substance is a consumer product, a manufacturing byproduct, or an element of a waste stream is irrelevant. Quantity or concentration is not a factor either; when Congress wanted to draw distinctions based on concentration or quantity, it expressly provided as much. *See* §§ 9602, 9603. *See also, e.g., Amoco Oil Co. v. Borden, Inc.*, 889 F.2d 664, 669 (5th Cir. 1989); *Exxon Corp.*, 744 F.Supp. at 485-86 n. 16; *United States v. Wade*, 577 F.Supp. 1326, 1339-40 (E.D.Pa.1983). When § 9601(14) is compared to sections containing threshold limits found elsewhere in CERCLA, *see, e.g.*, §§ 9602, 9603, and within other environmental statutes, *see, e.g.*, §§ 6903(5), 6921(d) (RCRA sections conditioning regulation applicability on threshold quantity waste generation); 33 U.S.C. §§ 1321(b)(4), 1317(d) (Clean Water Act conditioning liability upon exceeding reportable quantities and effluent standards), it is plain that the definition does not depend on the concentration of the substance present. Thus, the concentration of hazardous substances in municipal solid waste—regardless of how low a percentage—is not relevant in deciding whether CERCLA liability is incurred.

Against this backdrop, the municipalities nonetheless contend that CERCLA's silence regarding municipal solid waste is evidence that Congress aimed to have it excluded from the definition of hazardous substances. Alternatively, the municipalities argue that Congress intended an exemption for household hazardous waste found in the Resource and Recovery Act

regulations to be incorporated, through § 9601(14)(C), thus excluding municipal solid waste from the definition of hazardous substances under CERCLA.

[15-17] We disagree with both contentions. The Act's silence on the subject of municipal solid waste is not evidence that such should be excluded from the definition of hazardous substances. To the contrary, § 9601(14)'s comprehensive definition of hazardous substances, coupled with the specific exclusions of oil and natural gas, leads to the opposite conclusion. Municipal waste need not be listed by name—instead of its constituent components—to fall within the Act. For us to consider the whole separate from its hazardous constituent parts would be to engage in semantic sophistry. When a mixture or waste solution contains hazardous substances, that mixture is itself hazardous for purposes of determining CERCLA liability. *See, e.g., Eagle-Picher*, 759 F.2d at 930-31; *Exxon Corp.*, 744 F.Supp. at 483-84; *Carolawn*, 21 E.R.C. at 2126. Liability under CERCLA depends only on the presence in any form of listed hazardous substances. Hence, if a municipality arranges for the disposal or treatment of waste containing substances listed as hazardous in any of the four identified environmental statutes or in Table 302.4, it may be held liable for contribution or response costs under the Act if a subsequent release or threatened release requires cleanup efforts.

B. Resource and Recovery Act Exemption for Household Waste

[18, 19] The municipalities strenuously insist further that the exemption for household hazardous waste—promulgated by EPA and subsequently confirmed in part by Congress—from certain regulatory requirements under the Resource and Recovery Act extends, through incorporation by reference, to the definition of hazardous substance under CERCLA. This latter argument, as the former, is not persuasive. The Resource and Recovery Act is designed primarily to regulate on-going treatment, storage, and disposal of solid and hazardous wastes. *See Aceto Agric. Chems.*, 872 F.2d at 1376-77. Pursuant to RCRA, EPA promulgated two distinct regulatory systems for the transportation of wastes and the operation of waste storage and disposal facilities: one for *solid* wastes (under Subpart D of RCRA, §§ 6941-49a); and the other for *hazardous* wastes (under Subpart C of RCRA, §§ 6921-39b). *Hazardous wastes*, identified in 40 C.F.R. §§ 261.30-33, are subject to more stringent standards than are solid wastes.

"In regulations identifying and listing hazardous wastes subject to the RCRA Subtitle C regulations, EPA excluded for regulatory purposes certain solid wastes from the definition of hazardous wastes, *even though these wastes might otherwise be considered hazardous wastes.*" Notification of Treatment, Storage and Disposal Facilities, 46 Fed.Reg. 22,144, 22,145 (1981) (emphasis added). The EPA included household wastes, under 40 C.F.R. § 261.4(b)(1), pursuant to Congressional plan, among those wastes excluded from the Resource and Recovery Act's Subpart C hazardous waste regulations. Subsequently, Congress "clarified" the household waste exclusion with respect to resource recovery facility regulations under that Act for the recovery of energy through the mass burning of municipal waste by adding § 3001(i). That section provides that such facilities are not deemed to be handling hazardous wastes if they receive only household waste and other solid waste not containing hazardous waste. § 6921(i). From this statutory exclusion, appellants assert that municipal solid waste cannot be a hazardous waste under CERCLA.

The household waste exclusion was promulgated pursuant to a Congressional scheme that such waste not be subjected to the same stringent standards during the day-to-day management of transportation, storage and disposal. The legislative history relied on by the EPA in promulgating the household waste exclusion follows Congress' narrow aim to exclude specific waste streams from Resource and Recovery Act coverage. *See, e.g.*, Identification and Listing of Hazardous Waste, 45 Fed.Reg. 33,084, 33,099 (1980); Hazardous Waste

Guidelines and Regulations, 43 Fed.Reg. 58,946, 58,969 (1978); S.Rep. No. 988, 94th Cong., 2d Sess. 15–16 (1976). The subsequent "clarification," already referred to, was passed four years after CERCLA's enactment. It applies only to resource recovery facilities. § 6921(i); *see also* H.R.Conf.Rep. No. 1133, 98th Cong., 2d Sess. 106 (1984), *reprinted in* 1984 U.S.Code Cong. & Admin.News 5576, 5649, 5677; S.Rep. No. 284, 98th Cong., 2d Sess. 61 (1983). This narrow RCRA exemption in no way limits the definition of hazardous substance under CERCLA. The EPA expressly recognized the exemption's limited scope when it stated that the exempted "[solid] wastes might otherwise be considered hazardous wastes." 46 Fed.Reg. at 22,145. To construe this exemption to apply also to CERCLA would frustrate that Act's broad remedial purposes as well as unjustifiably expand the scope of the Resource and Recovery Act's regulations.

[20] Congress and the EPA have carefully distinguished between *wastes*, to which the Resource and Recovery Act applies, and *substances*, to which CERCLA applies. *See, e.g.*, §§ 6901 *et seq.* (particularly § 6903(5)); §§ 9601 *et seq.* (particularly § 9601(14)); S.Rep. No. 988, 94th Cong., 2d Sess. 15–16 (1976); 40 C.F.R. § 261.(4)(b); 46 Fed.Reg. at 22,145; EPA Directive Number 9574.00–1 Clarification of Issues Pertaining to Household Hazardous Waste Collection Programs (Nov. 1, 1988) (EPA Directive 9574.00–1); 54 Fed. Reg. at 51,073; *see also United States v. Conservation Chem. Co.*, 619 F.Supp. 162, 239 (W.D.Mo.1985). It may be seen therefore that the exemption which appellants urge should be extended to CERCLA applies to household *waste*. CERCLA, though, applies to hazardous *substances*. This statutory and regulatory distinction is a substantial one and should be preserved, absent a clear legislative intent to the contrary.

[21] In addition, application of the Resource and Recovery Act's regulations turns in part upon threshold quantity or concentration requirements—considerations which are irrelevant in defining hazardous substances under CERCLA. RCRA contains, for example, a small quantity generator exemption that imposes more stringent Subpart C regulations upon persons generating in excess of threshold quantities. *See* § 6921(d). The household hazardous waste exemption is consistent with this strategy because the concentration of hazardous waste is small relative to the total volume of household waste. 54 Fed.Reg. at 51,074. On the other hand, incorporating such a concentration/toxicity exemption into CERCLA is not consistent with CERCLA provisions that impose liability—when a release occurs that warrants a cleanup response—regardless of the amount of hazardous substances present.

[22] Nor does including wastes that are not subject to the stringent Subpart C regulations under the Resource and Recovery Act within the definition of hazardous substances under CERCLA create a conflict between the two statutes. Subpart C imposes tough standards for operating *active* toxic waste sites, but does not cover sites operated *prior* to its enactment, *nor* sites where the owner is unknown or bankrupt, *nor* does it address spills, illegal dumping or releases generally. RCRA is preventative; CERCLA is curative. It does not follow that because the environmental risk posed by household waste is deemed insufficient to justify the most stringent regulations governing its day-to-day handling that the environmental harm caused when that risk is realized is insufficient to require holding liable those responsible for that harm. In fact, the EPA expressly recommended that household waste, though exempt from subtitle C regulations, should be managed as a hazardous waste. EPA Directive 9574.00–1 at p. 2. The agency has also noted that the additional safeguards of management under Subpart C regulations merely *reduce* the likelihood of liability arising under CERCLA. *See id. See also* Solid Waste Disposal Facility Criteria, 56 Fed.Reg. 50,978 (1991) (to be codified at 40 C.F.R. pts. 257, 258) (final rule creating new criteria, more stringent than Subpart D but less stringent than Subpart C, for municipal solid waste landfills). Even total compliance with Subpart C regulations will not prevent releases or avoid CERCLA liability. Similarly, the increased likelihood of a release occurring pursuant to Subpart D regulations does not necessarily suggest a proportional increased likelihood that a response will be warranted under CERCLA, because of the small concentrations of hazardous substances found in wastes regulated under that Subpart.

[23] Other courts have concluded that exemptions from Resource and Recovery Act coverage do not extend so far as to exclude those materials from the definition of hazardous substances under CERCLA. *See, e.g., Eagle-Picher*, 759 F.2d at 927 (exclusion in § 9601(14)(C) for material suspended from RCRA regulation by Congress restricted in application to that subsection). We agree that had Congress aimed to exempt such materials from § 9601(14) it could have placed the exemption explicitly in the section exactly as it did with petroleum and natural gas. *See id.; see also State of Idaho v. Hanna Mining Co.*, 699 F.Supp. 827, 833 (D.Idaho 1987), *aff'd*, 882 F.2d 392 (9th Cir.1989); *Metate Asbestos Corp.*, 584 F.Supp. at 1147 (asbestos mill and mine wastes statutorily exempt from RCRA are hazardous substances under CERCLA, §§ 9601(14)(D), (E)); *Transportation Leasing Co. v. California*, 32 E.R.C. 1499, 1501, 1990 WL 300777 (C.D.Cal.1990) (RCRA exemption for household waste does not extend to the CERCLA definition for hazardous substances). Where a substance is not exempted from the definition of hazardous substance set forth in CERCLA, but merely is exempted from regulation under a separate statute, we decline to incorporate the exemption into § 9601(14). A regulatory exemption cannot take precedence over Congress' concerns spelled out in § 9601(14) of the Act.

Finally, the municipalities point to § 9603(c) of CERCLA as supporting their argument that Congress sought to exclude municipal solid waste comprised primarily of household waste from § 9601(14). Section 9603(c) sets forth notification requirements regarding solid waste storage, disposal, and treatment facilities, but expressly limits those requirements to facilities "at which hazardous substances (*as defined in section 9601(14)(C) of this title*) are or have been stored" (emphasis added). The municipalities assert that the EPA excluded household waste from its notification requirements because the agency recognized that household waste is exempt from CERCLA in its entirety.

[24] Quite the contrary, the EPA recognized that its notification requirements pursuant to § 9603(c) could apply, according to Congress' mandate, only to those hazardous substances identified under § 9601(14)(C). *See* 46 Fed.Reg. at 22,145 ("Section [9601(14)(C)] of the Act refers only to those hazardous substances that are hazardous wastes identified under or listed pursuant to Section 3001 of RCRA"). Hence, the agency realized that Congress expressly planned that the identification of substances as hazardous under the other subsections of § 9601(14) would not be affected by a contrary determination under RCRA. Contrary to the municipalities' argument, the EPA's exemption of household wastes from *notification* requirements under CERCLA does not suggest that disparate treatment of municipal solid waste under the Act's *liability* provisions is appropriate.

C. Legislative History

Although appellants recognize that the legislative history discussing municipal waste is meager, they contend that combined with legislative debate regarding the general aim of CERCLA, the history evinces such a clearly expressed legislative purpose, *see Consumer Product Safety Commission*, 447 U.S. at 108, 100 S.Ct. at 2056, that we should disregard the apparently contrary language of the Act itself. In this regard the municipalities rely heavily upon statements by Rep. Stockman, who, in opposition to H.R. 7020 (a bill offered as an amendment to the Resource and Recovery Act, which was superseded when the Senate bill, S.1480, was ultimately enacted separately as CERCLA) criticized the unrestrained and unlimited powers the bill would delegate to the EPA and the number

of items the Resource and Recovery Act would consider hazardous. 126 Cong.Rec. H9438–41 (Sept. 23, 1980). Rep. Stockman's own proposed amendment to the bill was eventually rejected by the House of Representatives, and most responses to his criticism focused on the powers of the EPA and the envisioned relationship between the state and federal governments. *See, e.g.*, 126 Cong.Rec. H9440–49 (Sept. 23, 1980) (statements of Reps. Florio, Gore, and Madigan).

Claiming that Congress agreed with Congressman Stockman's remarks, appellants urge that the bill actually passed did not envision such a broad scope as to include household wastes among hazardous substances. Yet, much of the legislator's criticism and the House's reaction to it is irrelevant in this case because it was directed towards the Resource and Recovery Act and not CERCLA. Congressman Stockman correctly understood that household waste may be exempt from coverage under the Resource and Recovery Act and that the toxic spill cleanup amendments, which he proposed changing, failed to include the same exemption; it is those amendments that were eventually enacted into CERCLA. *See* Dissenting Views, Comm. on Interstate and Foreign Commerce, H.R.Rep. No. 1016, 96th Cong., 2d Sess., pt. 1, 72 (1980), *reprinted in* 1980 U.S.Code Cong. & Admin.News 6119, 6148; *see also* 126 Cong.Rec. H9443 (Sept. 23, 1990) (statement of Rep. Florio, in response to Rep. Stockman, reading a letter from the National Conference of State Legislatures and the National Governors' Association agreeing that, "in order to allow recovery of Superfund expenditures and to provide an incentive for proper care to all parties connected with hazardous waste, all major Superfund bills contain rigorous liability provisions.... [The] NCSL and NGA support the applications of liability schemes to all parties, *including states and localities* when circumstances merit. No one disputes the principle that those who contribute to the problem should share in the cost of cleanup. Imposition of a comprehensive liability provision will assure that this principle is obs[illegible]") (emphasis added).

Examination of the legislative history reveals no further discussion relating to whether municipal solid waste could trigger liability under CERCLA. Rather, most of the debate upon which the municipalities would have us rely focused on Congress' scheme to hold the parties responsible for releases liable for the ensuing cleanup costs, and not taxpayers generally. *See, e.g.*, 126 Cong.Rec. H9162 (Sept. 19, 1980) (statement of Rep. Florio); *id.* at H9157 (statement of Rep. Carter); 126 Cong.Rec. S15,003 (Nov. 24, 1980) (statement of Sen. Leahy); H.R.Rep. No. 1016, 96th Cong., 2d Sess., pt. II, pp. 5, 33 (1980), *reprinted in* 1980 U.S.Code Cong. & Admin.News 6151, 6153; S.Rep. No. 848, 96th Cong., 2d Sess. 13, 98 (1980).

Appellants apparently believe this notion that "the responsible party pays" excludes situations where the responsible party happens to be a municipality disposing of solid waste. To impose CERCLA liability on these local governments results, appellants continue, in taxpayers within their jurisdictions shouldering the costs of cleanup. We agree that this will inevitably be the result, but are unable to agree that it is adverse to Congress' aim. To the contrary, a narrow interpretation of CERCLA that exempts municipalities arranging for the disposal of municipal solid waste from liability increases the probability that cleanup costs will never be recovered, and will be paid instead from the Superfund funded in part by the taxpayers at large. To accept the municipalities' argument that the municipal waste exemption in the Resource and Recovery Act should apply to CERCLA would free a potentially responsible party from liability, in blatant contravention of the statute's goals.

Although municipalities do not benefit in a proprietary sense from arranging for the disposal of municipal solid waste, their taxpayers do obtain a benefit—given the necessity of disposal of such waste. Thus, our refusal to exempt such waste from the definition of hazardous substance under CERCLA cannot be said to create an irrational and clearly unintended result. *See United States v. Rutherford*, 442 U.S. 544, 555, 99 S.Ct. 2470, 2477, 61 L.Ed.2d 68 (1979). On this question, review of the legislative history reveals a picture more confusing than pellucid, and a Congressional purpose not so discernible that it should cause us to depart from the plain meaning of § 9601(14).

D. EPA Interpretation

[25] The municipalities next argue that the EPA interprets CERCLA to impose no liability on municipalities arranging for the disposal of municipal refuse containing primarily household wastes. The EPA, they state, has created in a policy notice a "rebuttable presumption that generation and transportation of municipal solid waste and domestic sewage sludge would not be deemed to incur CERCLA liability." We concede that a court should defer to EPA's reasonable construction of CERCLA, absent a clearly expressed contrary Congressional purpose. *See, e.g., Chevron U.S.A. Inc. v. Natural Resources Defense Council, Inc.*, 467 U.S. 837, 842–45, 104 S.Ct. 2778, 2781–83, 81 L.Ed.2d 694 (1984). EPA's interpretation of CERCLA, as the agency charged with its administration, will be followed so long as it " 'is based on a permissible construction of the statute' " and " 'there are [not] compelling indications that it is wrong.' " *Weeks v. Quinlan*, 838 F.2d 41, 43–44 (2d Cir.1988). Thus, to be accorded deference, EPA's construction of CERCLA need not be one we would have chosen, nor the only reasonable one permitted by the Act's language. *See, e.g., Chevron*, 467 U.S. at 843 n. 11, 104 S.Ct. at 2782 n. 11.

We do not dispute appellants' characterization of how EPA's interpretation should be treated. Rather, we disagree with appellants' characterization of EPA's interpretation itself. Here, in fact, the EPA interprets CERCLA to *impose* liability on municipalities arranging for the disposal of municipal waste at sites that release or threaten the release of hazardous substances. Appellants' view of the EPA's pronouncements on the issue is more wish than reality, especially in light of the EPA's opposition to appellants' arguments in the district court.

In taking this somewhat disingenuous position, the municipalities primarily rely on the agency's Interim Municipal Settlement Policy, which was intended "to provide interim guidance to EPA Regional offices on how they should exercise their enforcement discretion." 54 Fed.Reg. at 51,071. Yet, decisions regarding enforcement discretion, which must reflect limited agency resources, enforcement priorities and other administrative constraints, do not necessarily mirror the liability scheme imposed by CERCLA. The statute does not forbid the EPA from selectively prosecuting only the major contributors to a hazardous response site. In exercising its enforcement discretion the agency routinely prosecutes only the largest contributors, or those with the greatest means to pay for the cleanup response costs, and leaves those defendants to seek, through third-party actions, contribution from any other liable polluters. The Interim Municipal Settlement Policy merely indicates that the EPA presently does not intend to pursue enforcement actions against municipalities generating or transporting municipal waste—regardless of whether hazardous substances are present—unless the total privately generated commercial hazardous substances are insignificant compared to the municipal waste. *Id.* at 51,072.

Moreover, there is no room for confusion as to the limited implications of EPA's prosecutorial position. The Interim Municipal Settlement Policy expressly warns, "[n]othing in the interim policy affects any party's potential legal liability under CERCLA ... [N]othing in the interim policy precludes a *third party from initiating a contribution action.*" *Id.* at 51,071 (emphasis added). In a similar vein, the notice states that CERCLA "does not provide an exemption from liability for municipalities ... [T]he statute does not provide an exemption from liability for municipal wastes." *Id.* at 51,074. In order to eliminate any lingering doubt regarding the EPA's interpretation of CERCLA, the agency states "[t]o the extent municipal wastes contain a hazardous substance that is covered under section 101(14) of CERCLA and there is a release or threatened release, such municipal wastes [illegible] fall

within the CERCLA liability framework." *Id.*

Other EPA pronouncements point out its unambiguous position and provide strong support for the argument that it does not believe Congress planned for municipal waste to be exempt from CERCLA. *See, e.g.*, EPA Directive 9574.00-1 at p. 2; EPA Note to Correspondents (July 17, 1991) (announcing that EPA will help develop guidelines for determining superfund liability for municipalities whose MSW contributed to a release or threatened release); Address by EPA Administrator William Reilly to National Association of Counties (July 16, 1991) (same); Statement of EPA Assistant Administrator for Solid Waste and Emergency Response Don R. Clay (July 29, 1991) (interim municipal settlement policy "describes [EPA's] exercise of enforcement discretion, not an interpretation of liability"). We conclude consequently that the EPA emphatically construes CERCLA to impose liability on municipalities disposing of household waste that contains hazardous substances.

CONCLUSION

Plaintiffs have sufficiently established a *prima facie* cause of action under CERCLA, including the first and third elements challenged by the appellants on this appeal. We are aware that holding the municipal defendants as responsible parties and including municipal solid waste within the definition of hazardous substances will have far reaching implications for municipalities and their taxpayers. But burdensome consequences are not sufficient grounds to judicially graft an exemption onto a statute, a graft that would thwart the language, purpose, and agency interpretation of the statute.

[26] Appellant municipalities are not without recourse to avoid inequitable and disproportionate burdens that may arise from their liability as third-party contributors. Courts have the authority to "allocate response costs among liable parties using such equitable factors as the court determines are appropriate." § 9613(f)(1). An array of equitable factors may be considered in this allocation process, including the relative volume and toxicity of the substances for disposal of which the municipalities arranged, the relative cleanup costs incurred as a result of these wastes, the degree of care exercised by each party with respect to the hazardous substances, and the financial resources of the parties involved. Consequently, the amount of liability imposed will not necessarily be a function solely of the total volume of municipal waste disposed of in the landfills, but rather will be a function of the extent to which municipal dumping of hazardous substances both engendered the necessity, and contributed to the costs, of cleanup.

In sum, the plain meaning of CERCLA, its stated purposes, the absence of a clearly expressed Congressional aim to the contrary, and unequivocal agency policy support the view that the municipal defendants are responsible parties under the Act and that the definition of hazardous substance under CERCLA includes municipal solid waste if that waste contains a hazardous substance, found in any amount, that is listed in any of the subsections of § 9601(14). The municipal defendants are not entitled to summary judgment as a matter of law declaring otherwise.

The judgment is affirmed.

UNITED STATES of America, Appellee,

v.

William REA, Getty Terminals Corp., and John Pabone, Defendants-Appellants,

Getty Terminals Corp., William Rea, John Pabone, and John Quock, Defendants.

Nos. 184, 187 and 191, Dockets 91-1177, 91-1182 and 91-1251.

United States Court of Appeals, Second Circuit.

Argued Oct. 16, 1991.

Decided March 13, 1992.

Defendants were convicted of conspiracy to defraud United States and federal tax evasion in connection with scheme to evade payment of federal excise taxes on sales of gasoline, following trial in the United States District Court for the Eastern District of New York, Leonard D. Wexler, J., and they appealed. The Court of Appeals, Kearse, Circuit Judge, held that: (1) opinion of lay witness that particular defendant must have known that he was participating in tax evasion scheme was not inadmissible on the sole ground that state of defendant's knowledge was an ultimate issue in the case; (2) the opinion was inadmissible on the ground that it was not helpful to the jury; (3) error in admitting the opinion was harmless; and (4) there was sufficient evidence as to intent.

Affirmed.

1. Conspiracy ⇐24(1)

In order to prove conspiracy, Government need not present evidence of explicit agreement; proof of tacit understanding will suffice. 18 U.S.C.A. § 371.

2. Conspiracy ⇐24(1)

Coconspirators need not have agreed on details of conspiracy, so long as they have agreed on the essential nature of the plan, and goals need not be congruent, so long as they are not at cross purposes. 18 U.S.C.A. § 371.

3. Conspiracy ⇐47(2)

Defendant's knowledge of conspiracy and participation in it with requisite criminal intent may be established through circumstantial evidence. 18 U.S.C.A. § 371.

4. Conspiracy ⇐40.3

Defendant need not have joined conspiracy at its inception in order to incur liability for unlawful acts of conspiracy committed both before and after he or she became a member. 18 U.S.C.A. § 371.

5. Criminal Law ⇐460

Witness' opinion that defendant must have known that he was participating in tax evasion scheme was not inadmissible on the sole ground that the state of defendant's knowledge was an ultimate issue in the case. Fed.Rules Evid.Rules 701, 704(a), 28 U.S.C.A.

6. Criminal Law ⇐449(2)

There is no theoretical prohibition against allowing lay witnesses to give their opinions as to the mental state of others, and thus rules as to opinion testimony do not, in principle, bar lay witness from testifying as to whether defendant in criminal prosecution had requisite knowledge; rule expressly forbidding opinion testimony by expert as to state of mind of defendant in criminal case where that mental state is an element of the crime does not apply to lay witnesses. Fed.Rules Evid.Rules 701, 704(a, b), 28 U.S.C.A.

7. Criminal Law ⇐449(1)

While lay opinion testimony is not totally excluded, there are two express preconditions to its admissibility; opinion evidence may be allowed only if court finds that opinion is rationally based on witness' own perception; and it is to be allowed only if court concludes that it will be helpful to a clear understanding of the testimony of the witness or the determination of a fact in issue. Fed.Rules Evid.Rules 602, 701, 701 note, 704(a), 704 note, 28 U.S.C.A.

8. Criminal Law ⇐449(1), 465

When lay witness has not identified objective bases for his opinion, proffered opinion fails to meet requirements that court assess whether opinion is rationally based on perceptions of witness and that opinion help the jury, while if witness fully describes what defendant was in position to observe or was told, opinion of witness as to defendant's knowledge will often not be "helpful" as required for admission. Fed. Rules Evid.Rule 701, 28 U.S.C.A.

9. Criminal Law ⇐449(1)

Even lay opinions that pass dual test of admissibility under rule authorizing lay opinion testimony may be excluded if court determines that admission of opinion will be cumulative or waste of time, or that its helpfulness is substantially outweighed by danger of unfair prejudice. Fed.Rules Evid.Rules 403, 701, 28 U.S.C.A.

10. Criminal Law ⇐464

Questions of whether proffered lay opinion is rationally based on knowledge of

B) *Judicial Review*

Although the Court finds that plaintiffs successfully allege standing, plaintiffs do not successfully allege a basis for judicial review. Neither the Klamath Basin Act nor the Trinity Basin Act (the "Acts") contain provisions granting a private right of action. Plaintiffs seek judicial review pursuant to the Administrative Procedure Act ("APA"), or, in the alternative, assert there to be an implied private right of action in the Acts.

i). *Judicial Review Under the APA.*

[24] Plaintiffs have generally alleged jurisdiction under the APA, 5 U.S.C. § 551 *et seq.* When jurisdiction is alleged pursuant to the APA, a plaintiff can claim a right to judicial review under § 10(a) of the APA, which provides:

> A person suffering legal wrong because of agency action, or adversely affected or aggrieved by agency action within the meaning of a relevant statute, is entitled to judicial review thereof.

5 U.S.C. § 702. This provision contains two separate requirements. First, the person claiming a right to sue must identify some "agency action" that affects her in the specified fashion. *Lujan v. National Wildlife Federation*, 497 U.S. 871, 881–82, 110 S.Ct. 3177, 3185, 111 L.Ed.2d 695 (1990). Second, the party must show she has suffered legal wrong, or has been adversely affected or aggrieved by that action. *Id.*

Plaintiffs' complaint refers to no specific action or inaction that violates the Acts, but only generally states that Secretary Babbitt has failed to implement measures to improve Klamath River Runs, including habitat improvement and fish planting measures. Plaintiffs do not attempt to meet the test laid out in *Lujan*. Rather, according to plaintiffs, because they allege general agency *inaction*, review is available under 5 U.S.C. § 706(1) which authorizes a district court to "compel agency action *unlawfully withheld or unreasonably delayed*" (emphasis added).

However, the claims plaintiffs present here do not match what is required to invoke 5 U.S.C. § 706(1). Courts which have reviewed claims of delay pursuant to this provision have done so in the context of specific allegations of inaction, usually in the context of delayed administrative review of a plaintiff's claim before an agency, or of delayed agency rulemaking. *See Telecommunications Research & Action v. F.C.C.*, 750 F.2d 70 (D.C.Cir.1984), *Public Citizen Health Research Group v. Comm'r Food and Drug Admin.*, 740 F.2d 21 (D.C.Cir.1984). Plaintiffs do not point to any authority to support their position that 5 U.S.C. § 706(1) can be utilized to review the kind of claim of agency inaction here made by plaintiffs.

ii). *Implied Private Right of Action.*

[25, 26] Plaintiffs alternatively contend that the Acts contain an implicit private right of action. Whether the Acts confer a private right of action is determined by the four-part test announced by the Supreme Court in *Cort v. Ash*, 422 U.S. 66, 78, 95 S.Ct. 2080, 2087, 45 L.Ed.2d 26 (1975): (i) the plaintiff must belong to the class for whose *especial* benefit the statute was created; (ii) the legislature must have shown an intent, either explicitly or implicitly, to create a private remedy; (iii) finding an implied cause of action must be consistent with the underlying purposes of the statute; and (iv) the cause of action must not be one that has traditionally been left to state law. An evaluation of the other elements is not necessary if the Court finds that Congress did not intend to create a private cause of action. *See California v. Sierra Club*, 451 U.S. 287, 298, 101 S.Ct. 1775, 1781, 68 L.Ed.2d 101 (1981); *Stupy v. Postal Service*, 951 F.2d 1079, 1081 (9th Cir. 1991).

There is no indication that Congress intended the Acts to provide a basis for a private right of action. The search for legislative intent begins with an examination of the language of the statute and then proceeds to a review of the legislative history and the application of traditional aids to statutory interpretation. *See Middlesex County Sewerage Auth. v. National Sea Clammers Ass'n*, 453 U.S. 1, 13, 101 S.Ct. 2615, 2622, 69 L.Ed.2d 435 (1981).

An examination of the language of the Acts indicates no intent to provide for a private cause of action. Rather, the text of the Acts provides that task forces to formulate management programs and to coordinate management activities among federal, state and local agencies are to be established. Trinity Basin Act, 98 Stat. at 2721, 2722-23 and Klamath Basin Act, 16 U.S.C. § 460ss-1 to -3. The Klamath Basin Act explicitly mandates membership of the Task Force to include representatives of the commercial salmon fishing industry, the in-river sport fishing community, the Department of the Interior, and the Hoopa Valley and Yurok Tribes, indicating that Congress intended the members of these various groups to communicate and resolve disputes through direction of the Task Force. 16 U.S.C. § 460ss-3(c)(1)(A).

Nor does the legislative history indicate any congressional intent to create a private cause of action. Plaintiffs point to legislative history discussing the seriousness of the degradation of the Klamath and Trinity Rivers and the frustration with past federal inaction felt by many who testified at the hearings on the proposed Acts. However, these facts do not suffice to show legislative intent to create a private remedy. Thus, plaintiffs successfully allege neither an implied private right of action nor a basis for judicial review pursuant to the APA.

Lastly, plaintiffs suggested in their written briefs that the Court should stay consideration of defendants' motion to dismiss pending intervention of either the Yurok or Hoopa Valley Tribes. Plaintiffs in fact assert that the parties have stipulated to such an intervention. However, defendants state that no such stipulation has been agreed to, and indeed, no such stipulation has been filed with the Court. Therefore, the Court declines to stay consideration of defendants' motion for this reason. Plaintiffs' sixth cause of action is therefore dismissed.[16]

CONCLUSION:

For the foregoing reasons, defendants' motion to file a supplemental opposition is granted, and plaintiffs' motion for a partial summary judgment is denied. Plaintiffs' motion to strike is denied, and defendants' motion to dismiss plaintiffs' remaining claims is granted. Further, as there are no remaining causes of action in the complaint, the action is dismissed in its entirety.

IT IS SO ORDERED.

16. Plaintiffs also allege in their complaint that their sixth cause of action should not be dismissed because it is based on Secretary Babbitt's "trust responsibility." There are no specific pleadings whatsoever regarding this violation, and plaintiffs only address this claim in their motion to dismiss by citing to two cases, which do not suffice to clarify how Secretary Babbitt has allegedly violated a "trust responsibility."

TRANSPORTATION LEASING COMPANY; et al., Plaintiffs,

v.

The STATE OF CALIFORNIA (CalTrans), et al., Defendants.

No. CV 89-7368-WMB.

United States District Court, C.D. California.

Jan. 29, 1993.

Potential responsible parties who settled claims asserted against them under the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) brought action against various cities, a county and county garbage disposal districts, and the California Department of Transportation, seeking to recover fair share of costs incurred under consent decree. In resolving various pretrial issues, the District Court, Wm. Matthew Byrne, Jr., Chief Judge, held that: (1) potentially responsible parties could sue for response costs, rather than suing for contribution; (2) public policy did not preclude imposition of liability; (3) cities, county and disposal districts, and Department "arranged" for transportation of waste within meaning of CERCLA; and (4) cities, county and disposal districts, and Department

"owned or possessed" waste for arranged disposal.

Ordered accordingly.

1. Health and Environment ⇐25.5(5.5)

For party to liable as "arranger" under CERCLA, substances disposed of must have been "hazardous" under CERCLA, party must have "owned or possessed" substances, and it must have "arranged" for their disposal. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, § 107(a)(3), 42 U.S.C.A. § 9607(a)(3).

See publication Words and Phrases for other judicial constructions and definitions.

2. Health and Environment ⇐25.5(5.5)

Whether private parties that had settled CERCLA claims asserted against them could bring suit to recover response costs against other potentially responsible parties, or instead had to maintain action for contribution, could be determined before trial, and did not have to await development of specific facts of case. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, §§ 107(a), 1113(f), 42 U.S.C.A. §§ 9607(a), 9613(f).

3. Health and Environment ⇐25.5(5.5)

Potentially responsible parties whose CERCLA liability was based on consent decree could maintain action against alleged arrangers to recover response costs, and were not restricted to maintaining action for contribution, although their response costs were not voluntarily incurred and though they were themselves potentially liable for contribution. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, §§ 107(a), 1113(f), 42 U.S.C.A. §§ 9607(a), 9613(f).

4. Health and Environment ⇐25.5(5.5)

State governmental body is not automatically foreclosed from CERCLA liability merely because it is acting in regulatory capacity pursuant to statutory mandate; state governmental entities may be liable for response costs under any statutorily enumerated circumstances from which they are not expressly exempted. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, § 107(a), 42 U.S.C.A. § 9607(a)

5. Health and Environment ⇐25.5(5.5)

Whether joint and several liability was available in suit to recover CERCLA response costs could not be determined before trial, because whether harm caused was divisible could not yet be determined. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, § 107(a), 42 U.S.C.A. § 9607(a).

6. Health and Environment ⇐25.5(5.5)

"De minimus non curat lex" (the law does not concern itself with trifles) is not available defense to liability for CERCLA response costs. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, § 107(a, b), 42 U.S.C.A. § 9607(a, b).

7. Health and Environment ⇐25.5(5.5)

Fact that cities' contract with waste haulers did not specifically mention hazardous substances did not prevent cities from being liable for CERCLA response costs as "arrangers." Comprehensive Environmental Response, Compensation, and Liability Act of 1980, § 107(a)(3), 42 U.S.C.A. § 9607(a)(3).

8. Health and Environment ⇐25.5(5.5)

Fact that cities' contracts with waste haulers did not mention disposal site did not prevent cities from being held liable for CERCLA response costs as "arrangers." Comprehensive Environmental Response, Compensation, and Liability Act of 1980, § 107(a)(3), 42 U.S.C.A. § 9607(a)(3).

9. Health and Environment ⇐25.5(5.5)

Cities that issued business licenses to private waste haulers permitting them to conduct business within city limits "arranged" for transport of waste for disposal, for purposes of determining arranger liability for CERCLA response costs. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, § 107(a)(3), 42 U.S.C.A. § 9607(a)(3)

See publication Words and Phrases for other judicial constructions and definitions

10. Health and Environment ⇐25.5(5.5)

County disposal districts that entered into contract with private disposal companies to collect, transport, and dispose of refuse "arranged" with transporter for transport of waste for disposal, for purposes of determining arranger liability for CERCLA response costs. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, § 107(a)(3), 42 U.S.C.A. § 9607(a)(3).

11. Health and Environment ⇐25.5(5.5)

County that disposed of some of its governmental waste by transporting that waste to disposal sites in county vehicles "arranged" for transport of its governmental waste for disposal, for purposes of determining arranger liability for CERCLA response costs. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, § 107(a)(3), 42 U.S.C.A. § 9607(a)(3).

12. Health and Environment ⇐25.5(5.5)

County that created garbage disposal districts and took a day-to day responsibility for their operation "arranged" for transport of residential, commercial and curbside governmental waste for transport, for purposes of determining arranger liability for CERCLA response costs. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, § 107(a)(3), 42 U.S.C.A. § 9607(a)(3).

13. Health and Environment ⇐25.5(5.5)

Fact that California Department of Transportation's excavation and hauling contract with private entity for removal of material from former landfill included provisions that hazardous waste was not to be taken to another site did not preclude Department from being held liable as "arranger" for CERCLA response costs incurred at other site. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, § 107(a)(3), 42 U.S.C.A. § 9607(a)(3)

14. Health and Environment ⇐25.5(5.5)

Additional evidence showing with greater factual specificity what contractor was hired to do and what it in fact did in construction of freeway was required before California Department of Transportation could be determined to have "arranged" for transport of construction waste for disposal, for purposes of determining arranger liability for CERCLA response costs. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, § 107(a)(3), 42 U.S.C.A. § 9607(a)(3).

15. Health and Environment ⇐25.5(5.5)

Ownership or possession of waste can be either actual or constructive, for purposes of determining arranger liability for CERCLA response costs. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, § 107(a)(3), 42 U.S.C.A. § 9607(a)(3).

16. Health and Environment ⇐25.5(5.5)

Cities "owned or possessed" their own governmental waste, for purposes of arranger liability for CERCLA response costs. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, § 107(a)(3), 42 U.S.C.A. § 9607(a)(3).

17. Health and Environment ⇐25.5(5.5)

Cities constructively "owned or possessed" residential and commercial waste collected under contractual arrangements, for purposes of determining arranger liability for CERCLA response costs, under either control test or nexus test, by virtue of their statutory duty to provide waste collection services and their control over aspects of waste handling and disposal from point after waste was generated to point it was hauled away by transport. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, § 107(a)(3), 42 U.S.C.A. § 9607(a)(3).

See publication Words and Phrases for other judicial constructions and definitions

18. Health and Environment ⇐25.5(5.5)

It is exercise of control, rather than authority to control, that is relevant inquiry in using control test to determine constructive ownership or possession of waste, for purposes of determining arranger liability for CERCLA response costs. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, § 107(a)(3), 42 U.S.C.A. § 9607(a)(3)

19. Health and Environment ⇐25.5(5.5)

Cities' duty to provide for waste disposal was fact tending to demonstrate exercise and control over waste, for purposes of determining arranger liability for CERCLA response costs. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, § 107(a)(3), 42 U.S.C.A. § 9607(a)(3).

20. Health and Environment ⇐25.5(5.5)

Neither cities' limited involvement in sites selection or their lack of proprietary interest in haulers compelled finding that cities did not constructively own or possess residential and commercial waste, for purposes of determining arranger liability for CERCLA response costs. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, § 107(a)(3), 42 U.S.C.A. § 9607(a)(3).

21. Health and Environment ⇐25.5(5.5)

Cities that issued business licenses to waste haulers to conduct business within city limits did not, solely by their statutory duty to provide for collection, constructively possess waste, for purposes of determining arranger liability for CERCLA response costs; additional evidence showing control would have to be presented. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, § 107(a)(3), 42 U.S.C.A. § 9607(a)(3).

22. Health and Environment ⇐25.5(5.5)

County and county disposal districts actually "owned and possessed" governmental waste they generated themselves, for purposes of determining arranger liability for CERCLA response costs. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, § 107(a)(3), 42 U.S.C.A. § 9607(a)(3).

23. Health and Environment ⇐25.5(5.5)

Fact that disposal companies were independent contractors did not preclude finding that county constructively owned or possessed residential and commercial waste, for purposes of determining arranger liability for CERCLA response costs. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, § 107(a)(3), (b)(3), 42 U.S.C.A. § 9607(a)(3), (b)(3).

24. Health and Environment ⇐25.5(5.5)

California Department of Transportation (CalTrans) "owned or possessed" material excavated from former landfill despite fact that excavated material, by contract, became property of excavation contractor, for purposes of determining arranger liability for CERCLA response costs. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, § 107(a)(3), 42 U.S.C.A. § 9607(a)(3).

25. Health and Environment ⇐25.5(5.5)

Exclusion from definition of "owner or operator" under CERCLA for governmental unit which acquired ownership or control of waste facility involuntarily did not prevent California Department of Transportation from being held liable as arranger for CERCLA response costs based upon its acquiring land through eminent domain and arranging to have material on that land transported for disposal. Comprehensive Environmental Response, Compensation, and Liability Act of 1980, §§ 101(20)(D), 107(a)(3), 42 U.S.C.A. §§ 9601(20)(D), 9607(a)(3).

AMENDED ORDER

WM. MATTHEW BYRNE, Jr., Chief Judge.

I. BACKGROUND

A. *History of the Action*

This action arises out of efforts to clean up hazardous substances at a facility in Monterey Park, California, known as the Operating Industries, Inc. (OII) landfill.

In 1988, the United States Environmental Protection Agency (EPA), the State of California, and the California Hazardous Substance Account sued a number of parties, including plaintiffs in this action, alleging that those parties were liable to perform certain remedial actions at the OII landfill and to reimburse the United States and the State of California for response costs incurred in abating various hazardous conditions at the landfill.

The 1988 action was settled with a Partial Consent decree entered on May 11, 1989. Under the terms of the decree, plaintiffs here agreed to perform certain work at the OII landfill and to pay approximately $61,000,000 to the EPA and the State of California. However, plaintiffs expressly reserved the right to assert claims for reimbursement and indemnification against other potentially liable persons who were not signatories of the decree.

Plaintiffs now assert that right by bringing this action against fourteen municipal defendants,[1] the County of Los Angeles and five County Garbage Disposal Districts (GDDs),[2] and the State of California Department of Transportation (CalTrans). Plaintiffs seek to recover from these defendants a fair share of the costs incurred pursuant to the Partial Consent Decree, on the grounds that (1) defendants either owned, operated, or utilized the OII landfill, and (2) defendants were not signatories of the decree.[3]

On December 5, 1990, the Court issued an Order denying in part and granting in part defendant cities' motion for an order specifying issues without substantial controversy. The Court granted defendant cities' motion to specify that "[r]ubbish generated by residences and businesses located within the city limits of defendant cities is not a 'hazardous substance' under CERCLA absent specific evidence that the particular rubbish generated by those residences and businesses that was disposed of at the OII landfill site contained 'hazardous substances' as defined by CERCLA § 101(14)" only to the extent that it sought a ruling that for arranger liability, plaintiffs must prove that the waste disposed of at the OII landfill contained "hazardous substances" under CERCLA. Additionally, the Court found that CERCLA § 101(14) does not expressly exempt from liability the disposal of household wastes. The Court denied defendants' motion with regard to all remaining issues presented.

In its order of September 24, 1991 (Sept. Order), the Court found the following issues were without substantial controversy:

1) A "release" of a "hazardous substance," as those terms are defined in CERCLA §§ 101(14), 101(33) has occurred at the OII landfill;

2) In connection with the OII site, plaintiffs have incurred "necessary costs of response" that are "consistent with the national contingency plan" within the meaning of CERCLA § 107(a)(4)(B);

3) By contracting with a disposal company for the collection and disposal of the waste of city residents, defendant City of Alhambra "by contract, agreement, or otherwise arranged for disposal ... or arranged with a transporter for transport for disposal" of that residential waste, within the meaning of CERCLA § 107(a)(3).

The Court further ruled that liability under § 107(a)(3) requires proof that defendants "owned or possessed" the hazardous substances for which defendants arranged for disposal and that plaintiffs could satisfy this requirement by showing constructive, as well as actual, ownership or possession.

II. DISCUSSION

[1] Plaintiffs claim defendants fall within the class of persons liable as an arranger under CERCLA § 107(a)(3). Arrangers liable under CERCLA include:

1. Plaintiffs originally named 29 cities as defendants. During 1991 plaintiffs dismissed five defendant cities: Baldwin Park, Artesia, Walnut, Santa Fe Springs, and City of Industry. In early 1992, plaintiffs settled with 10 defendant cities: El Monte, Sierra Madre, South El Monte, Pasadena, San Marino, Huntington Park, Norwalk, Beverly Hills, La Puente, and Bell Gardens. Stipulated judgments have been entered as to these ten defendants.

2. The West Hollywood Sherman GDD is not named as a separate defendant because it no longer exists. The court will still make findings of fact and conclusions of law concerning this GDD because the County is liable for waste collected in West Hollywood-Sherman to the same extent that it is liable for the waste collected in the five GDDs that are named defendants. Furthermore, in this order, when the Court refers to the GDDs as a group, without naming them individually, the parties should understand that West Hollywood Sherman is meant to be included within the meaning of the term "GDDs."

3. On July 16, 1990 the Court granted the municipal defendants' motion to dismiss the pendent state claims. The only claims remaining in this action are the first and the second claims under CERCLA and the portion of the fifth claim under the Declaratory Judgments Act.

> Any person who by contract, agreement, or otherwise arranged for disposal or treatment, or arranged with a transporter for transport for disposal or treatment, of hazardous substances owned or possessed by such person, by any other party or entity, at any facility or incineration vessel owned or operated by another party or entity and containing such hazardous substances.

CERCLA § 107(a)(3); 42 U.S.C. § 9607(a)(3). To be liable as an arranger, the substances disposed of must have been "hazardous" under CERCLA,[4] the liable party must have "owned or possessed" the substances, and it must have "arranged" for their disposal.

Phase I of this action presents three categories of issues. First, the parties have identified several legal issues for pre-trial legal determination. Second, the Court will determine whether defendants "arranged with a transporter for transport for disposal" within the meaning of CERCLA § 107(a)(3). Lastly, the Court will determine if defendants "owned or possessed" the waste for which they arranged disposal within the meaning of CERCLA § 107(a)(3).[5]

A. *Pre-Trial Legal Determinations*

1. *Do Plaintiffs Have Standing To Sue For Cost Recovery Under CERCLA § 107 or Are They Limited to Remedies For Contribution Under CERCLA § 113(f)?*

Plaintiffs have brought this action under CERCLA § 107(a)(3), which imposes liability on arrangers for "all costs of removal or remedial action incurred by the United States Government or a State or an Indian tribe not inconsistent with the national contingency plan; (B) any other necessary costs of response incurred by any other person consistent with the national contingency plan." CERCLA § 107(a)(4); 42 U.S.C. § 9607(a)(4). Defendants argue plaintiffs may not bring an action to recover response costs under § 107.

Each group of defendants takes a different position on this issue. The County defendants argue the enactment of CERCLA § 113(f) in the Superfund Amendments and Reauthorization Act of 1986 (SARA), makes an action for contribution under § 113(f) the only remedy available to plaintiffs against defendants. Section 113(f)(1) provides that:

> Any person may seek contribution from any other person who is liable or potentially liable under section 9607(a) of this title, during or following any civil action under section 9606 of this title or under section 9607(a) of this title. . . In resolving contribution claims, the court may allocate response costs among liable parties using such equitable factors as the court determines are appropriate.

CERCLA § 113(f)(1); 42 U.S.C. § 9613(f)(1).

Defendant cities argue this issue is not susceptible to pre-trial determination because the decision on whether to utilize § 107(a) or § 113(f) depends on the specific facts of this case. CalTrans does not address the § 107/§ 113 issue in its papers.

a. *Can This Issue Be Determined Pre-Trial?*

[2] In addition to determining whether or not plaintiffs can bring suit under § 107, the parties have requested the Court to decide before trial whether defendants can be held jointly and severally liable. Defendant cities seem to view the question of whether plaintiffs can sue under § 107 as another way of determining the joint and several liability question.

Defendant cities apparently equate § 107 with joint and several liability and § 113(f) with several liability. The cities argue plaintiffs are limited to a contribution remedy under § 113(f) absent a showing justifying joint and several liability. Unless an individual defendant can show that the harm caused by that defendant is divisible and that a reasonable basis for apportionment of damages exists, liability under § 107 is joint and several. *United States v. Chem-Dyne*, 572 F.Supp. 802, 811 (S.D.Ohio 1983).

Under § 113(f), on the other hand, the court may allocate response costs using such equitable facts as the court determines appropriate. According to defendant cities, neither the § 107/§ 113 issue nor the issue of joint and several liability can be determined before trial because the divisibility of the harm depends on the particular facts of this case.

The question of whether plaintiffs can bring suit under § 107(a) does not depend on whether defendants may be held jointly and severally liable. Similarly, the question of whether joint or several liability applies does not determine whether this action can be brought under § 107 or must be brought under § 113. This issue can be resolved before trial.

b. *Can Plaintiffs Bring This Action under § 107?*

[3] Section 107 makes certain persons, such as arrangers, liable for any "necessary costs of response incurred by any other person consistent with the national contingency plan." CERCLA § 107(a)(4); 42 U.S.C. § 9607(a)(4). In its September order, the Court found plaintiffs have incurred "necessary costs of response . . . consistent with the national contingency plan." Sept. Order at 20. Plaintiffs thus conclude they are entitled to bring an action against alleged arrangers such as defendants under § 107(a) to recover the response costs they have incurred.

In the face of this statutory language, the County defendants argue that potentially responsible parties (PRPs) whose liability is based on a judgment (such as the consent decree entered against plaintiffs) are entitled to contribution under § 113(f)(1) but not full indemnity under § 107(a). Section 107(a)(4) allows a plaintiff to recover all its response costs. Section 113(f)(1), on the other hand, does not allow a plaintiff to recover all its costs. Instead, it allows persons liable or potentially liable under § 107(a) to "seek contribution from any other person who is liable or potentially liable" and provides that the court "may allocate response costs among liable parties using such equitable factors as the court determines are appropriate." 42 U.S.C. § 9613(f)(1).

When it was originally enacted, CERCLA did not provide a mechanism for a PRP held jointly and severally liable for cleanup costs to seek contribution from other PRPs. In the absence of such a provision, courts implied a private right of contribution into the statutory scheme. *See Sand Springs Home v. Interplastic Corp.*, 670 F.Supp. 913, 916–17 (N.D.Okla.1987); *United States v. New Castle County*, 642 F.Supp. 1258 (D.Del.1986). Congress ratified this approach in SARA by adding § 113(f) to CERCLA.

The County argues § 113(f)'s enactment demonstrates that indemnity under § 107 is limited to situations in which a PRP promptly and voluntarily cleans up a site without the necessity of a lawsuit. The County defendants claim PRPs such as plaintiffs, who incur response costs pursuant to a court order (in plaintiffs' case, the partial consent decree in the 1988 action), cannot obtain full indemnity under § 107(a) but are instead limited to contribution under § 113(f)(1) from other PRPs.

The cases which have compared and contrasted sections 107(a) and 113(f) have concluded PRPs can bring actions under § 107(a). In *General Elec. Co. v. Litton Indus. Automation Sys., Inc.*, defendant Litton contended plaintiff General Electric (GE) could not bring suit under § 107(a) because GE did not incur response costs until after GE was threatened with a lawsuit. 920 F.2d 1415, 1418 (8th Cir.1990), *cert. denied*, 499 U.S. 937, 111 S.Ct. 1390, 113 L.Ed.2d 446 (1991). The court rejected this argument, holding that:

> the motives of the private party attempting to recoup response costs under 42 U.S.C. § 9607(a)(4)(B) are irrelevant. The purpose of allowing a private party to recover its response costs is to encourage timely cleanup of hazardous waste sites. This purpose would be frustrated if a plaintiff's motives were subject to question. We

4. Under CERCLA, the term "hazardous substance" is defined broadly and includes any substance designated as hazardous by the EPA under CERCLA § 102 or other legislative acts including the Solid Waste Disposal Act, the Clean Air Act, the Clean Water Act of 1977, and the Toxic Substances Control Act. CERCLA § 101(14); 42 U.S.C. § 9601(14).

5. This phase of this action was heard on stipulated facts. The Court adopts the stipulated facts as its findings of fact and issues this order as its conclusions of law. Fed.R.Civ.P. 52.

not look at the impetus behind a plaintiff's decision to begin the cleanup process; we will look only to see if there has been a release or threatened release for which the defendant is responsible.

Id.

United States v. Kramer contains perhaps the most detailed discussion of the differences between § 107(a) actions and § 113(f) actions. 757 F.Supp. 397 (D.N.J.1991). In *Kramer*, the United States brought an action against various defendants under § 107(a) to recover its response costs. Defendants argued the government's action was properly characterized as a § 113(f) action because the United States generated large amounts of the waste at the site. *Id.* at 413. The court held:

> The Government's potential liability for contribution does not affect this section 107(a) response cost recovery action. The Government's potential liability alters neither the type of affirmative defenses permissible under section 107(a), nor the Government's right to full recovery of its response costs. Defendants are correct that the Government's ultimate recovery of its response costs would be decreased, once it was found liable for contribution and the amount to be apportioned to it of total response costs was determined. However, it is in the nature of the claims made, that even when, as here, a section 107(a) claim co-exists in a single action with section 113 contribution claims, defendants' liability on the Government's section 107(a) claim almost certainly will be determined before the Government's liability for contribution.

Id. at 414. The court went on to state:

> the structure of CERCLA does not preclude consideration of equitable factors, including the liability of a PRP who was (or is) a plaintiff in a section 107 action. Rather, CERCLA separates those equitable factors from section 107 and considers them in a section 113 contribution action. . . . [S]ections 107 and 113 serve distinct purposes. . . . Section 107 permits the Government or a private party to go in, clean up the mess, pay the bill, then collect *all* its costs not inconsistent with the NCP from other responsible parties—even if plaintiff was also responsible for the contamination. Any PRP is entitled under section 113 to bring a contribution action against other PRPs including the PRP who previously cleaned up the mess and was paid for its trouble through a section 107 proceeding—to apportion costs equitably among all the PRPs. Practically speaking, section 107 permits a PRP, including the Government, to collect all its response costs, even those that same PRP may be required to pay back to other PRPs as its equitable share in a section 113 proceeding.

Id. at 416 (emphasis in original). Other courts have reached the same conclusion, albeit not necessarily for the same reasons. *E.g., Sand Springs Home v. Interplastic Corp.*, 670 F.Supp. 913, 916 (N.D.Okla.1987); *Chemical Waste Management, Inc. v. Armstrong World Indus., Inc.*, 669 F.Supp. 1285, 1291–92 (E.D.Pa.1987).[6] The County defendants distinguish the above cases by arguing that each involved either an innocent landowner, *e.g., General Electric*, or PRPs who voluntarily incurred response costs before being forced to do so by judicial decree, *e.g., Kramer*.

CERCLA permits plaintiffs to sue under § 107. Section 113 does not abrogate § 107 but instead codifies the efforts of federal courts to imply a contribution remedy to assist those held jointly and severally liable. No reported decision has drawn the distinction suggested by the County defendants, and numerous courts have rejected similar arguments. Plaintiffs have incurred necessary response costs, and § 107(a)(4)(B) explicitly states arrangers shall be liable for any necessary costs of response incurred by any other person consistent with the NCP.

2. *Do Public Policy Considerations and Regard For a City's Sovereign Power to Protect the Public Health, Safety, and Welfare Preclude Imposition of CERCLA Liability?*

Defendant cities claim they are exempt from CERCLA liability because they were exercising sovereign power to abate a public nuisance and to protect the public health, safety, and welfare. Defendants claim both CERCLA § 101(20)(D) and considerations of public policy support such an exemption. In making this argument, defendant cities rely almost exclusively on *Lincoln v. Republic Ecology*, 765 F.Supp. 633 (C.D.Cal.1991).

In *Lincoln*, plaintiffs alleged the City of Pasadena was liable as an arranger based upon contracts which the city had signed with private companies providing for the towing of vehicles abandoned on public streets. The *Lincoln* court granted the city's motion for summary judgment, holding that:

> an unmistakable purpose behind CERCLA's strict liability standard was to force parties who *profit* from the use and generation of hazardous wastes, or directly cause or contribute to their release, to account, in the pricing of their products, for the environmental externalities associated with improper disposal. This rationale simply does not apply to the City's abatement of public nuisances.

Id. at 635–36 (emphasis in original). The court went on to state that:

> strict liability under CERCLA should not attach to government entities engaged in legitimate sovereign, as opposed to proprietary or commercial, functions. This is especially true when, as here, the City had no "hands on" involvement with or control over the hazardous substances and enjoyed no commercial interest or benefits by virtue of the regulatory legislation.

Id. at 637–38. The municipal defendants conclude that *Lincoln* should apply to exempt them for liability for their conduct in this case because their regulation of waste collection, like the City of Pasadena's activity in *Lincoln*, constituted a "non-contributory exercise of sovereign power."

Faced with this argument, the Second Circuit recently rejected defendant cities' interpretation of *Lincoln* in *B.F. Goodrich Co. v. Murtha*, 958 F.2d 1192, 1199 (2d Cir.1992). In *Murtha*, plaintiffs and defendants alleged several municipalities were liable under § 107(a)(3) because they had arranged for the disposal and/or treatment of hazardous substances at two landfills. *Id.* at 1196. The municipalities cited *Lincoln* for the proposition that liability could not attach to municipalities which arranged for the disposal or treatment of hazardous substances in their sovereign capacity. *Id.* at 1199. The Second Circuit rejected the argument, stating:

> We regard *Lincoln* as merely holding that the city's activities in that case, taken in furtherance of its sovereign function to abate public nuisances, were insufficient to give rise to "arranger" status for purposes of liability under CERCLA. *See id.* at 636–38. To the extent *Lincoln* can be construed as extending the "function as a sovereign" exception beyond the liability provision for owners or operators to that for arrangers, we disagree with it. Congress limited the sovereign function exception to those situations where liability is premised on the state or local government entity being an "owner or operator" of a vessel or facility. Nothing in the language of the Act suggests that it be extended.

Id. (citations omitted).

[14] *Martha's* interpretation of *Lincoln* is persuasive. A governmental body is not automatically foreclosed from CERCLA liability merely because it is acting in a regulatory capacity pursuant to a statutory mandate. *United States v. New Castle County*, 727 F.Supp. 854, 875 (D.Del.1989). Indeed, this Court has already implicitly rejected the cities' argument in its September order by finding a defendant city could be held liable under § 107(a)(3) if the prerequisites of the statute are met. Congress intended that state governmental entities be liable along with everyone else for cleanup costs recoverable under CERCLA. Thus, they may be liable under any circumstance described in § 107(a) from which they were not expressly excluded. *Cf. Pennsylvania v. Union Gas Co.*, 491 U.S. 1, 7, 109 S.Ct. 2273, 2278, 105 L.Ed.2d 1 (1989).

3. *Joint and Several Liability*

[15] All defendants dispute whether plaintiffs are entitled to joint and several liability. Regardless of whether plaintiffs are allowed to sue under § 107(a) or are limited to § 113(f), the County defendants and Cal

6. *Chemical Waste* does not properly differentiate between § 107 and § 113. In that case, the court allowed plaintiffs to sue under § 107, which imposes liability for any necessary response costs, but then applied the legal standards of § 113 to limit plaintiff's potential recovery in the § 107 action. *See* 669 F.Supp. at 1292 & n. 10.

Trans argue this Court should apply several liability. Defendant cities appear to argue the Court's decision on whether or not to impose joint and several liability follows from its decision with regard to whether plaintiffs can sue under § 107(a). The cities argue the Court has discretion to impose or not to impose joint or several liability depending on the facts of the case and equitable considerations, citing *Allied Corp. v Acme Solvents Reclaiming, Inc.*, 691 F.Supp. 1100, 1116 (N.D.Ill.1988); *United States v. Chem-Dyne Corp.*, 572 F.Supp. 802, 808 (S.D.Ohio 1983).

In *Chem-Dyne*, the court interpreted the scope of liability under § 107:

> If the harm is divisible and if there is a reasonable basis for apportionment of damages, each defendant is liable for only the portion of harm he himself caused. In this situation, the burden of proof as to apportionment is upon each defendant. On the other hand, if the defendants caused an indivisible harm, each is subject to liability for the entire harm.

572 F.Supp. 802, 811 (S.D.Ohio 1983). The majority of courts have adopted *Chem-Dyne*'s holding. *See O'Neil v. Picillo*, 883 F.2d 176, 178 (1st Cir.1989) (citing cases), *cert. denied*, 493 U.S. 1071, 110 S.Ct. 1115, 107 L.Ed.2d 1022 (1990).[7]

Plaintiffs assert courts have consistently and unanimously held CERCLA imposes joint and several liability. *E.g., County Line Investment Co v. Tinney*, 933 F.2d 1508, 1516 (10th Cir.1991); *O'Neil*, 883 F.2d at 178 79; *United States v. Monsanto Co.*, 858 F.2d 160, 171 (4th Cir.1988), *cert. denied*, 490 U.S. 1106, 109 S.Ct. 3156, 104 L.Ed.2d 1019 (1989). However, plaintiffs themselves recognize that the majority of courts will apportion damages when defendants can demonstrate that the harm is divisible. *E.g., O'Neil*, 883 F.2d at 178.

With regard to the issue of joint and several liability, the Court holds joint and several liability applies under § 107. However, individual defendants may be entitled to several liability if they can show the harm they caused is divisible. The parties dispute the divisibility of the harm caused at the OII site. While plaintiffs claim the harm at OII is indivisible, defendants claim the harm is divisible. The parties have presented no evidence to suggest whether the harm is divisible or indivisible because the question of divisibility involves issues not before the Court in this phase of the case. Because the divisibility of the harm cannot be resolved at the present time, the Court's final decision on joint and several liability must wait until it considers evidence relating to the divisibility of harm.

4. *Does the Doctrine of 'De Minimis Non Curat Lex' Absolve Defendants From Liability?*

[6] Defendant cities argue that a cost recovery or contribution action under CERCLA amounts to an equitable proceeding for restitution in which equitable defenses, particularly 'de minimis non curat lex,' should apply. Some courts have recognized the availability of equitable defenses in cost recovery actions under CERCLA § 107. *E.g., United States v. Mottolo*, 695 F.Supp. 615, 626-27 (D.N.H.1988); *United States v. Hardage*, 116 F.R.D. 460 (W.D.Okla.1987).

Relying on the above, defendant cities argue the Court can apply, if appropriate, 'de minimis non curat lex' (the law does not concern itself with trifles) to this action. Defendant cities realize the application of this doctrine depends on the introduction of evidence regarding the amount and toxicity of the waste attributable to the cities. Accordingly, the cities request only a ruling that they may assert this defense at the appropriate time.

Section 107(a) states those arranging for the transport for disposal of hazardous waste which they own or possess shall be liable "[n]otwithstanding any other provision or rule of law, and subject only to the defenses set forth in subsection (b) of this section." Section 107(b) does not set forth the defense of 'de minimis non curat lex.'

Numerous courts have construed § 107(b) as precluding all defenses not enumerated in CERCLA. *E.g., United States v. Bliss*, 667 F.Supp. 1298, 1304 (E.D.Mo.1987); *United States v. Stringfellow*, 661 F.Supp. 1053, 1061-62 (C.D.Cal.1987). Given the Court's finding that plaintiffs can sue under § 107(a), 'de minimis non curat lex' is not an available defense because § 107(b) limits the defenses available. "The principle of 'de minimis non curat lex' (the law does not concern itself with trifles) is simply not a defense to CERCLA liability." *United States v. Western Processing Co.*, 734 F.Supp. 930, 936 (W.D.Wash.1990).

B. *The First Trial Phase*

Plaintiffs claim defendants fall within the class of persons liable as an arranger under CERCLA § 107(a)(3). Arrangers liable under CERCLA include:

> Any person who by contract, agreement, or otherwise arranged for disposal or treatment, or arranged with a transporter for transport for disposal or treatment, of hazardous substances owned or possessed by such person, by any other party or entity, at any facility or incineration vessel owned or operated by another party or entity and containing such hazardous substances.

CERCLA § 107(a)(3); 42 U.S.C. § 9607(a)(3). To be liable as an arranger, the substances disposed of must have been "hazardous" under CERCLA, the liable party must have "owned or possessed" the substances, and it must have "arranged" for their disposal.

For the purposes of this phase of the trial, the Court will determine only if the defendants "arranged for transport for disposal" of waste "owned or possessed" by defendants. Later phases of this action will determine issues such as the volume of the waste and whether or not the waste contained hazardous substances.

1. *Arranger Issues*

In its 1st order, the Court delineated three principles which have emerged from case law to guide determinations of whether a particular contract or agreement constitutes an arrangement for disposal:

> First, courts have not hesitated to look beyond a defendant's characterizations to determine whether a transaction in fact involved an arrangement for the disposal of a hazardous substance. Second, if persons have a legal responsibility for disposal of hazardous substances, they cannot evade liability if they do nothing and simply "close their eyes" to the method of disposal of their hazardous substances. Third, courts have stated that "a liberal judicial interpretation of the term is required in order (to) achieve CERCLA's 'overwhelming remedial' statutory scheme."

Sept. Order at 26 (citations omitted). The Court applied these principles to find that defendant City of Alhambra could be held liable as an arranger because the city had contracted with a disposal company for the transportation and disposal of its residential waste.

a. *The Defendant Cities*

Plaintiffs argue each defendant city arranged for transport for disposal by contracting with waste haulers to pick up waste within the city. In addition, plaintiffs argue five defendant cities (Bell, Commerce, Compton, Lynwood, and South Gate) arranged for disposal by licensing waste haulers to operate within those cities.

i. *Contractual Agreements With Waste Haulers*

[7] Defendant cities raise three basic arguments on the arranger by contract issue. First, they point to the language of § 107(a)(3), which states defendants must have arranged for the disposal of "hazardous substances." Defendant cities claim they are not arrangers because the contracts at issue said nothing about hazardous substances.

It is undisputed defendant cities contracted with disposal companies to transport residential, commercial, and governmental waste for disposal. In other cases, courts have not hesitated to look beyond a defendant's characterizations to determine whether a transaction in fact involved an arrangement for the disposal of a hazardous substance. *See* Sept.

7. Defendant cities further suggest the Gore Amendment factors present consideration the Court can take into account when determining whether joint and several liability is appropriate. *United States v. A & F Materials*, 578 F.Supp. 1249, 1256-57 (S.D.Ill.1984). As plaintiffs point out, however, most appellate decisions have refused to follow the approach of *A & F Materials*

Order at 26. The fact that the contracts at issue in this case did not specifically mention hazardous substances does not prevent defendant cities from being held to be arrangers.

[8] Second, defendant cities point out that § 107(a)(3) imposes liability on those who arrange for transport for disposal to a "facility." Defendant cities argue their contracts with private waste haulers do not qualify as arrangements because no city picked OII as the site for waste from within the city to be dumped.

In its most recent order, the Court noted that "it is well settled that one who contracts for disposal has 'arranged' for disposal even if the contract does not mention the disposal site." Sept. Order at 22. One who contracts for disposal has "arranged" for disposal even if the contract does not mention the disposal site. *Id.* at 48. Defendant cities did not have to pick OII as the site to qualify as arrangers under § 107(a)(3). By contracting with disposal companies, the municipal defendants arranged for waste to be taken to a facility. The fact they did not pick OII as the final destination is not determinative.

Lastly, defendant cities reiterate the policy arguments they make in asserting their sovereign power defense, namely that considerations of public policy should prevent the imposition of CERCLA liability on municipalities. As stated above, the Court does not find those policy arguments persuasive under the facts of this case. As stated below, the Court finds the stipulated facts demonstrate each municipal defendant arranged with a transporter for transport for disposal within the meaning of CERCLA § 107(a)(3).

In discussing the arranger issue, plaintiffs and defendant cities have divided the waste collected by the disposal companies into three categories. The first category is "residential waste"– refuse from households and apartments within the defendant city. The second category is "commercial waste"--refuse from businesses located with the defendant city. The third category is "governmental waste"--waste from governmental operations and city refuse receptacles. In making its findings, the Court adopts this nomenclature.

1. *Alhambra*

Alhambra arranged with a transporter for transport for disposal of residential waste by contracting with CV Disposal and Athens Disposal from 1960 to 1984. [1.2; 1.3] Alhambra's contracts with Athens Disposal further provided Athens would collect, transport, and dispose of governmental waste and some commercial waste. [1.4; 1.5] Based on the stipulated facts, the Court finds Alhambra arranged with a transporter for transport for disposal of residential, commercial, and governmental waste within the meaning of CERCLA § 107(a)(3) from 1960 to 1984.

2. *Bell*

Bell contracted with System Disposal Services, Inc. (System Disposal) to collect, transport, and dispose of residential and governmental waste from 1970 to 1981. [2.2] The Court finds Bell arranged with a transporter for transport for disposal of residential and governmental waste within the meaning of CERCLA § 107(a)(3) from 1970 to 1984.

3. *Commerce*

From 1962 until 1977, Commerce contracted with O.G. Cannavo to collect, transport, and dispose of residential waste. [5.2] From 1977 until 1984, Commerce contracted with Metropolitan Waste Disposal Company to collect, transport, and dispose of residential waste. [5.4] The Court finds Commerce arranged with a transporter for transport for disposal of residential waste within the meaning of CERCLA § 107(a)(3) from 1962 until 1984.

In 1976 and 1977, the Commerce-Cannavo contracts required Cannavo to collect, transport and dispose of Commerce governmental refuse. [5.3] The Commerce-Metropolitan contracts from 1977 to 1984 required Metropolitan to collect, transport, and dispose of Commerce governmental refuse.' [5.5] The Court finds Commerce arranged with a transporter for transport for disposal of governmental waste within the meaning of CERCLA § 107(a)(3) from 1976 to 1984.

4. *Compton*

Compton contracted with Murcole, Inc. to collect, transport and dispose of residential waste from 1969 to 1984 except for a portion of East Compton and the 'Nestor Tract' from 1975–1980. [6.2] The Compton–Murcole contracts also covered Compton governmental waste from 1969 to 1984. [6.3] The Court finds Compton arranged with a transporter for transport for disposal of residential and governmental waste within the meaning of CERCLA § 107(a)(3) from 1969 to 1984.

5. *Cudahy*

From 1981 to 1984, Cudahy contracted with System to collect, transport and dispose of residential and governmental waste from Cudahy. [7.2] The Court finds Cudahy arranged with a transporter for transport for disposal of residential and governmental waste within the meaning of CERCLA § 107(a)(3) from 1981 to 1984.

6. *Lynwood*

Lynwood contracted with CV Disposal Service from 1962 to 1984 to collect, transport and dispose of residential and commercial waste. [12.2; 12.3] From 1978 to 1984, the Lynwood-CV contracts required CV to collect, transport, and dispose of governmental waste as well. [12.4] The Court finds Lynwood arranged with a transporter for transport for disposal within the meaning of CERCLA § 107(a)(3) of residential and commercial waste from 1962 to 1984, and for disposal of government waste from 1978 to 1984.

7. *Maywood*

From 1958 to 1972 Maywood contracted with Pacific Waste Disposal Company, a transporter, to collect, transport, and dispose of residential and governmental waste. [13.3; 13.8] From 1958 to 1970, the Maywood-Pacific contracts required Pacific to collect, transport, and dispose of commercial waste. [13.6] From 1972 to 1984, Maywood contracted with System Disposal to collect, transport, and dispose of residential and governmental waste. [13.4; 13.9]

The Court finds Maywood arranged with a transporter for transport for disposal of residential and governmental waste within the meaning of CERCLA § 107(a)(3) from 1958 to 1984. The Court further finds Maywood arranged with a transporter for transport for disposal of commercial waste within the meaning of CERCLA § 107(a)(3) from 1958 to 1970.

8. *Montebello*

From 1952 to 1958, Montebello contracted with Michael Harabedian and George Slater to collect, transport, and dispose of residential and commercial waste. [14.2] From 1962 to 1984, Montebello contracted with Athens Disposal to collect, transport, and dispose of residential, commercial, and governmental waste. [14.7; 14.10]

The Court finds Montebello arranged with a transporter for transport for disposal within the meaning of CERCLA § 107(a)(3) of residential and commercial waste from 1952–1958 and from 1962–1984. The Court further finds Montebello arranged with a transporter for transport for disposal of governmental waste within the meaning of CERCLA § 107(a)(3) from 1962–1984.

9. *Monterey Park*

Monterey Park contracted with Michael Harabedian to collect, transport, and dispose of residential waste from 1947–1958. [15.2] Monterey Park contracted with CV Disposal to collect, transport, and dispose of residential and governmental waste from 1960–1970. [15.3; 15.5] From 1970 until 1984, Monterey Park contracted with Athens Disposal to collect, transport, and dispose of residential and governmental waste. [15.4; 15.6]

The Court finds Monterey Park arranged with a transporter for transport for disposal of residential and governmental waste within the meaning of CERCLA § 107(a)(3) from 1960-1984. The Court also finds Monterey Park arranged with a transporter for transport for disposal of residential waste within the meaning of CERCLA § 107(a)(3) from 1947 1958.

10. *Rosemead*

Rosemead contracted with Dick Griegorian (doing business as Griegorian Disposal Service and Modern Service Co.) to collect, transport, and dispose of residential waste from 1961 until 1984. [18.2] During the period 1965 1984, the Rosemead-Griegorian contracts required Griegorian to collect, transport, and dispose of commercial and governmental waste. [18.3; 18.4]

The Court finds Rosemead arranged with a transporter for transport for disposal of residential waste within the meaning of CERCLA § 107(a)(3) from 1961-1984, and for disposal of residential, commercial, and governmental waste within the meaning of CERCLA § 107(a)(3) from 1965-1981.

11. *San Gabriel*

San Gabriel contracted with George Solomon to collect, transport and dispose of residential and commercial waste from 1948 to 1956. [19.2] During 1954-1956, the San Gabriel-Solomon contracts provided that Solomon would also collect, transport, and dispose of governmental refuse. [19.3] From 1957 to 1964, San Gabriel contracted with Community Disposal Company to collect, transport, and dispose of residential, commercial, and governmental waste. [19.8; 19.9]

In 1956-1957, and from 1964-1984, San Gabriel contracted with San Gabriel Valley Disposal Company (also known as San Gabriel Disposal Company) to collect transport and dispose of residential, commercial, and governmental waste. [19.6; 19.6; 19.7] Based on this series of contracts, the Court finds San Gabriel arranged with a transporter for transport for disposal of residential, commercial, and governmental waste within the meaning of CERCLA § 107(a)(3) from 1948-1981.

12. *South Gate*

From 1956-1957, South Gate contracted with System Disposal to collect, transport, and dispose of residential and commercial waste. [23.2] From 1957-1962, South Gate contracted with Santa Ana Commercial for collection, transportation, and disposal of residential and commercial waste. [23.4] From September 26 to December 15, 1962, the South Gate-Santa Ana contract provided for collection, transportation and disposal of South Gate governmental waste as well. [*Id.*]

From 1962-1967, South Gate contracted with Andrew Hohn to collect, transport, and dispose of residential, commercial, and governmental was[illegible]23.5] From 1967 to 1984, South Gate c[illegible]ed with CV Disposal Service to collect, transport, and dispose of residential and governmental waste. [23.6]

The Court finds that by making these contracts, South Gate arranged with a transporter for transport for disposal of residential waste within the meaning of CERCLA § 107(a)(3) from 1955-1984, of commercial waste within the meaning of CERCLA § 107(a)(3) from 1955-1967, and of governmental waste within the meaning of CERCLA § 107(a)(3) from Sept. 26, 1962 to 1984.

13. *South Pasadena*

From 1950 to 1979, South Pasadena contracted with South Pasadena Rubbish Company and South Pasadena Disposal Company to collect, transport, and dispose of residential and commercial waste. [24.1; 24.2] From 1979 to 1984, South Pasadena contracted with Ronara to collect, transport, and dispose of residential, commercial, and governmental waste. [24.4; 24.5; 24.6] Based on these contracts, the Court finds South Pasadena arranged with a transporter for transport for disposal of residential and commercial waste within the meaning of CERCLA § 107(a)(3) from 1950-1984, and of governmental waste within the meaning of CERCLA § 107(a)(3) from 1979-1984.

14. *Temple City*

From 1960 to 1984, Temple City contracted with Community Disposal to collect, transport and dispose of residential, commercial, and governmental waste. [25.1; 25.2; 25.3] Accordingly, the Court finds Temple City arranged with a transporter for transport for disposal of residential, commercial, and governmental waste within the meaning of CERCLA § 107(a)(3) from 1960-1984.

b. *Licenses*

[9] Plaintiffs claim the issuance of business licenses by five municipal defendants (Bell, Commerce, Compton, Lynwood, and South Gate) which permitted a waste hauler to conduct business within city limits constituted an "arrangement" subjecting the cities to liability under CERCLA § 107(a)(3). These five defendants claim the licenses they issued were generic licenses no different than those issued to other types of businesses. Plaintiffs claim the licenses issued by these five defendants were not generic business licenses but explicit permits to collect and dispose of refuse. The parties have stipulated that Bell licensed a hauler to collect and dispose of commercial waste [2.33], Commerce licensed a hauler to collect and dispose of commercial waste [5.16], Compton licensed a hauler to engage in the business of rubbish collection within Compton [6.57], Lynwood licensed two haulers to operate refuse collection and disposal businesses in Lynwood [12.21, 12.23], and South Gate licensed three different haulers to collect and dispose of commercial waste [23.57 23.59].

California law requires municipal corporations like defendants "to make adequate provision for solid waste handling ... within their respective jurisdictions." Cal.Pub.Res. Code § 40002. Municipalities can fulfill this duty by delegating it to private parties through a "nonexclusive franchise." *Id.* at § 40059.[8] Plaintiffs argue Bell, Commerce, Compton, Lynwood, and South Gate arranged within the meaning of CERCLA § 107(a)(3) because each had a statutory duty to arrange for disposal of waste, their licensing of private haulers was an approved method for carrying out this duty, and they exercised control over aspects of waste collection and disposal. In particular, plaintiffs argue Bell, Compton, and South Gate extensively controlled disposal companies they licensed. Each of these three defendants contracted with a transporter to collect and dispose of residential waste and licensed that same transporter to collect and dispose of commercial waste.

Defendants argue the issuance of a business license does not constitute a contract or agreement by which the city arranges for disposal because a license permits, but does not require, a licensee to conduct the business for which it is licensed. Defendants suggest plaintiffs' license argument would hold the Department of Motor Vehicles liable as an arranger because it issued vehicle registrations and drivers' licenses to waste haulers.

In support of their argument that they are not liable as arrangers, defendants rely on *Hassayampa Steering Comm. v. Arizona* 768 F.Supp. 697 (D.Ariz.1991). In *Hassayampa*, the plaintiffs alleged the State of Arizona was liable as an "arranger" for the disposal of hazardous substances because it issued manifests which permitted hazardous waste to be deposited at a landfill. The court refused to impose liability, holding that:

> the State's issuance of a permit does not constitute an agreement with the permittee. The manifest merely allowed the waste generator or transporter to deposit the waste at [the site] and did not require such disposal, even after the manifest was approved.

768 F.Supp. at 700.

Hassayampa, however, is distinguishable from this case. The *Hassayampa* court rested it decision on the issue of "owned or possessed," *not* the arranger issue. Indeed, the *Hassayampa* court noted that plaintiffs' arguments "may establish the State's activities constituted 'arranging' for disposal." *Id.* Defendant cities' DMV licensing argument is without merit. By issuing drivers' licenses and vehicle registrations, the DMV does not arrange for transport for disposal but instead only permits garbage trucks to be driven. While DMV has a duty to register such vehicles, it does not have a duty to arrange for garbage disposal such as defendant cities have. Thus, DMV's licensing cannot amount to an arrangement for disposal.

Based on the stipulated facts discussed below, the Court finds defendants Bell, Commerce, Compton, Lynwood, and South Gate arranged with a transporter for transport for disposal within the meaning of CERCLA § 107(a)(3) by issuing business licenses to private haulers. Given these defendants' statutory and common law duty to assure the pick-up and disposal of residential trash, defendants' licensing of private haulers amounted to an arrangement.

1. *Bell*

In 1977 and in 1982, Bell licensed System Disposal to collect and dispose of commercial waste. The Court finds Bell arranged with a transporter for transport for disposal of commercial waste within the meaning of CERCLA § 107(a)(3) in 1977 and 1982.

[illegible] Code §§ 66755 et seq.

2. *Commerce*

In 1983 and 1984, Commerce licensed Athens Disposal to collect and dispose of commercial refuse. The Court finds Commerce arranged with a transporter for transport for disposal of commercial waste within the meaning of CERCLA § 107(a)(3) in 1983 and 1984.

3. *Compton*

From 1972 to 1977, Compton licensed Murcole to engage in the business of commercial waste collection within Compton. The Court finds Compton arranged with a transporter for transport for disposal of commercial waste within the meaning of CERCLA § 107(a)(3) from 1972 to 1977.

4. *Lynwood*

From 1963 to 1969, Lynwood issued business licenses to Lynwood Disposal Service to operate a refuse collection and disposal business. In 1962, 1965–1969, 1973–1975, 1977, and 1979–1981, Lynwood licensed System Disposal to operate a refuse collection and disposal business. Lynwood required its licensees to apply for a special permit, including fingerprinting, a police background check, and approval by the City Council. [Exh. 1758; 1763; 1780] The Court finds Lynwood arranged with a transporter for transport for disposal within the meaning of CERCLA § 107(a)(3) in 1962, 1963–1969, 1973–1975, 1977, and 1979–1981.

5. *South Gate*

South Gate licensed three companies to collect and dispose of commercial waste. From 1967 to 1984, South Gate licensed CV Disposal. From 1964 to 1984, South Gate licensed System Disposal. From 1970 to 1984, South Gate licensed Murcole. Like Lynwood, South Gate had special permitting features for waste haulers. [Exh. 2344; 2345; 2355] Accordingly, the Court finds South Gate arranged with a transporter for transport for disposal from 1967 to 1984.

2. *The County Defendants*

[10] The Athens Woodcrest-Olivita GDD, Belvedere GDD, Firestone GDD, Mesa Heights GDD, and Walnut Park GDD each entered contracts with private disposal companies to collect, transport, and dispose of refuse. For the same reasons outlined above, the Court finds each GDD arranged for transport for disposal of waste within the meaning of CERCLA § 107(a)(3). With respect to the County itself, however, the issue presented is somewhat different. However, the Court finds it too arranged for disposal

a. *Athens Woodcrest Olivita GDD*

Stipulated facts 26.1 to 26.6 demonstrate the Athens Woodcrest Olivita GDD arranged with a transporter for transport for disposal of residential, commercial, and curbside public waste from 1963 to 1984. Accordingly, the Court finds the Athens-Woodcrest-Olivita GDD arranged with a transporter for transport for disposal of residential commercial, and curbside public waste within the meaning of CERCLA § 107(a)(3) from 1963 to 1984.

b. *Belvedere GDD*

Stipulated facts 27.1 to 27.7 demonstrate the Belvedere GDD arranged with a transporter for transport for disposal of residential and commercial waste from 1953 to 1983. Stipulated facts 27.9 to 27.10 demonstrate the Belvedere GDD arranged with a transporter for transport for disposal of curbside government waste from July 1, 1961 to June 30, 1983. Accordingly, the Court finds the Belvedere GDD arranged with a transporter for transport for disposal of residential and commercial waste within the meaning of CERCLA § 107(a)(3) from 1953 to 1983, and of curbside governmental waste within the meaning of CERCLA § 107(a)(3) from July 1, 1961 to June 30, 1983.

c. *Firestone GDD*

Stipulated facts 28.1 to 28.4 reveal the Firestone GDD arranged with a transporter for transport for disposal of residential, commercial, and curbside government waste from 1971 to 1984. Accordingly, the Court finds the Firestone GDD arranged with a transporter for transport for disposal of residential, commercial, and curbside governmental waste within the meaning of CERCLA § 107(a)(3) from 1971 to 1984.

d. *Mesa Heights GDD*

Stipulated facts 29.1 to 29.4 reveal the Mesa Heights GDD arranged with a transporter for transport for disposal of residential, commercial, and curbside governmental waste from 1969 to 1974. Accordingly, the Court finds the Mesa Heights GDD arranged with a transporter for transport for disposal of residential, commercial, and curbside governmental waste within the meaning of CERCLA § 107(a)(3) from 1969 to 1974.

e. *Walnut Park GDD*

Stipulated facts 30.1 to 30.13 reveal the Walnut Park GDD arranged with transporters for the transport for disposal of residential, commercial, and curbside governmental waste from 1964 to 1983. Accordingly, the Court finds the Walnut Park GDD arranged with a transporter for transport for disposal of residential, commercial, and curbside governmental waste within the meaning of CERCLA § 107(a)(3) between 1964 and 1983.

f. *West Hollywood-Sherman GDD*

Stipulated facts 31.1 to 31.4 demonstrate that the West Hollywood-Sherman GDD arranged with a transporter for transport for disposal of residential, commercial, and curbside public waste from July 1953 through December 1957 and July 1961 through June 1984. Accordingly, the Court finds that the West Hollywood-Sherman GDD arranged with a transporter for transport for disposal of residential, commercial, and curbside public waste within the meaning of CERCLA § 107(a)(3) from July 1953 through December 1957 and July 1964 through June 1984.

g. *County of Los Angeles*

Plaintiffs argue the County itself is liable for two types of arrangements. First, the County arranged to haul some waste generated by County facilities in County-owned trucks. Second, plaintiffs claim the County is liable for all waste collected under the GDDs' contracts because the County also acted as an arranger with respect to that waste.

i. *Waste Hauled in County Owned Trucks*

[11] From 1958 until 1981, the County disposed of some of its governmental waste by transporting that waste to disposal sites in County vehicles. [425] By transporting that waste in County vehicles, the County arranged for disposal of its governmental waste. [426] Accordingly, the Court finds the County arranged for transport for disposal of its governmental waste from 1958 through 1981 within the meaning of CERCLA § 107(a)(3) by transporting that waste in County owned vehicles.

ii. *Waste Collected Under GDD Contracts*

[12] Plaintiffs claim the County acted as an arranger with respect to waste collected under the GDDs' contracts because the County created, controlled, and operated every aspect of the GDDs. The County responds that it is an entity separate from the GDDs and is thus not liable for the conduct of the GDDs. The County argues plaintiffs seek to impose some version of corporate alter ego liability on it for the acts of its GDDs.

The Los Angeles County Board of Supervisors created the GDDs to organize garbage collection services and to provide for payment of those services. [32.49, 32.50] The Board of Supervisors governed the GDDs [32.51], and County employees had daily responsibility for operation of the GDDs [32.60]. The GDDs had no offices [32.61], owned no property [32.62], had no employees [32.59], and had no physical existence separate from the County [32.63]. Plaintiffs claim the County prepared for and brought about the transport and disposal of waste by drafting, approving, executing, monitoring, and enforcing the contracts between the GDDs and the private disposal companies.

The County claims the GDDs are entities separate from the County. The GDDs have their own budgets and pay for their expenses by charging district residents a user fee. *See generally* Cal.Pub.Res.Code §§ 49000 *et seq.* The County argues that transferring the GDDs' potential liability to it would impose an inequitable burden on County residents located outside the boundaries of the GDDs.

The Court finds the County did arrange for transport for disposal of waste by creating and controlling the GDDs. By creating the GDDs and taking day to day responsibility for their operation, the County itself arranged for transport for disposal of residen

tial, commercial, and curbside governmental waste from within the boundaries of the GDIs within the meaning of CERCLA § 107(a)(3).

3 *CalTrans*

Plaintiffs claim CalTrans arranged with a transporter for transport for disposal by contracting with private companies during two freeway projects, the Pomona Freeway (State Route 60) and the Century Freeway (Interstate 105). CalTrans disputes that these contracts amounted to an arrangement for transport for disposal within the meaning of CERCLA § 107(a)(3).

a. *Willco Site*

[13] While building the Century Freeway, CalTrans hired Papac & Sons, a private contractor, to excavate and remove material (Willco material) from the Willco site (a former landfill in Lynwood). [33.1] From March 1983 to June 30, 1983, some of the excavated Willco material was deposited at the OII site by Papac & Sons. [33.4] Plaintiffs argue CalTrans arranged with a transporter for transport for disposal by contracting with Papac & Sons to excavate and remove the Willco material.

CERCLA § 101(29) equates the CERCLA definition of "disposal" with that of the Solid Waste Disposal Act, namely:

> the discharge, deposit, injection, dumping, spilling, leaking, or placing of any solid waste or hazardous waste into or on any land or water.

42 U.S.C. § 6903(3). Plaintiffs claim CalTrans arranged for disposal because it contracted with Papac & Sons to excavate material and then discard it by placing it elsewhere.

CalTrans asserts it is not liable as an arranger because its contract with Papac & Sons explicitly provided that any hazardous materials were not to go to a class II landfill such as the OII site. Under CalTrans' contract with Papac & Sons, CalTrans had no discretion to decide where the excavated material would be disposed other than requiring that material was to be tested during excavation and was not to go to a class II landfill such as OII if hazardous. Section 107(a)(3) imposes liability on persons who "arranged for disposal or treatment, or arranged with a transporter for transport for disposal or treatment, of hazardous substances . . ." CalTrans claims it does not fall within this language because it adhered to its contract by hiring Calscience Research to provide environmental consulting services at the Willco site, including monitoring the excavation being performed by Papac & Sons and characterizing the excavated material as hazardous or non-hazardous. [33.7]

Despite the exclusionary language of the contract, the Court finds CalTrans did arrange for disposal of the Willco site material. CalTrans hired a transporter to take the Willco material away, and that material ended up at OII. If that waste contained hazardous substances, CalTrans cannot escape liability by pointing to a contractual clause stating hazardous waste should not have been taken to OII. Instead, CalTrans will have to wait until a later phase of this action to rebut plaintiffs' proffered evidence that the Willco material which went to the OII site contained hazardous substances.

b. *Pomona Freeway Right of Way*

[14] The current day Pomona Freeway traverses the OII site. In building the freeway, CalTrans contracted with Milburn & Sansone, a private contractor, to construct a portion of the Pomona Freeway between Woods Avenue and Arroyo Drive, which included the right of way. [33.15] Pursuant to this contract, CalTrans or its agents excavated and removed material (the Pomona material) from the right of way. [33.16] Plaintiffs argue CalTrans thus arranged for disposal of the Pomona material. CalTrans argues it did not "arrange" for disposal of the Pomona material because there is no evidence that any of the material excavated during this grading was transported and placed at the OII site.[9]

Plaintiffs have not provided enough evidence in this first phase for the Court to determine whether CalTrans "arranged" with regard to any excavated Pomona Freeway right of way material. Plaintiffs need to show with greater factual specificity what Milburn & Sansone was hired to do and what they in fact did. Pursuant to the stipulation between the parties, plaintiffs can (if they desire) present disputed evidence on this issue before the Court makes its final ruling on this issue.

9. CalTrans also argues plaintiffs have not produced evidence that any material which was transported and deposited at OII contained hazardous substances. This issue is appropriately contested in a later phase of this action.

C. *Owned or Possessed Issues*

[15] CERCLA § 107(a)(3) provides that persons who have "arranged for disposal . . . , or arranged with a transporter for transport for disposal" are liable for those hazardous substances they "owned or possessed." The Court has previously held arranger liability under § 107(a)(3) requires that defendants own or possess waste in addition to arranging with a transporter for transport for disposal. Sept. Order at 44. Ownership or possession under § 107(a)(3) can be either actual or constructive. *Id.*

1. *The Municipal Defendants*

a. *Waste Actually Owned or Possessed*

i. *Governmental Waste*

[16] With regard to the "owned or possessed" issue, all defendant cities have stipulated that they arranged with a transporter for transport for disposal of their governmental waste. These municipal defendants admit they owned and possessed their governmental waste. Thus, each defendant city "owned or possessed" the governmental waste for which it arranged for transport for disposal within the meaning of CERCLA § 107(a)(3).

ii. *Residential and Commercial Waste*

In their trial brief, plaintiffs further argued defendant cities actually owned or possessed (as opposed to constructively owned or possessed) the residential and commercial waste for which they arranged transport because (1) individual citizens and businesses abandoned their waste on city property by placing it out for collection, (2) defendants had complete authority to decide what happened to the waste once it was set out for collection, and (3) the ownership interest of defendant cities in the refuse was acknowledged by both the cities and their disposal companies.

At oral argument, plaintiffs abandoned this argument. However, plaintiffs still assert these facts tend to show constructive ownership or possession of residential and commercial waste. Because plaintiffs no longer assert defendant cities' actually owned or possessed residential and commercial waste, the Court need not address plaintiffs' actual ownership or possession argument further.

b. *Constructive Ownership or Possession*

[17] Plaintiffs contend that defendant cities constructively owned or possessed residential and commercial waste. In its prior order, the Court stated:

> the broad remedial objectives of CERCLA counsel in favor of holding that this requirement may be satisfied by a showing of constructive, rather than actual, ownership or possession. Constructive ownership or possession will be established by a demonstration of the existence of defendants' exercise of control over the waste.

Sept. Order, at 44. Plaintiffs argue defendants constructively owned or possessed residential and commercial waste by controlling aspects of waste handling and disposal from the point after waste was generated by a resident or business to the point it was hauled away by the transporter.

Courts have developed two different tests to judge whether a defendant constructively owns or possesses waste within the meaning of CERCLA § 107(a)(3). The first focuses on a defendant's authority to control waste. The second examines whether defendant had a sufficient nexus with the actual owner or possessor to satisfy § 107(a)(3)'s "owned or possessed" requirement. The Court agrees with the parties that these two tests are essentially different formulations of the same legal standard. However, the Court's discussion is divided into "control" and "nexus" sections to reflect the different formulations developed by these two strands of case la

1. The Control Test

1. Exercise of Control or Authority to Control?

[18] In its prior order, the Court held constructive ownership or possession "will be established by a demonstration of the existence of defendants' exercise of control over the waste." Sept. Order at 44. Plaintiffs attempt to loosen this test by arguing authority to control, rather that the existence of actual control, can satisfy the "owned or possessed" requirement.

California law "authorize[s] and require[s] local agencies, as subdivisions of the state, to make adequate provision for solid waste handling." Cal.Pub.Res.Code § 40002. While state statutes authorizing and requiring waste collection only date back to 1989,[10] California state courts have long held local political subdivisions (such as defendant cities) have a duty to collect waste or cause it to be collected. *E.g., Matula v. Superior Court*, 146 Cal.App.2d 93, 303 P.2d 871 (1956). Plaintiffs argue defendant cities constructively owned or possessed residential and commercial waste because the cities had the power under state law to exercise complete dominion over the handling and disposal of such waste.

In making this argument, plaintiffs primarily rely on two cases. In *United States v. Northeastern Pharmaceutical & Chemical Co.*, a company supervisor claimed he could not be held individually liable under § 107(a)(3) because the company, not the supervisor himself, owned or possessed the waste in question. The Eight Circuit held the supervisor was not exempt from liability because "[i]t is the authority to control ... that is critical under the statutory scheme." 810 F.2d 726, 743 (8th Cir.), *cert. denied*, 484 U.S. 848, 108 S.Ct. 146, 98 L.Ed.2d 102 (1987) (*NEPACCO*).

Plaintiffs also rely on *United States v. Bliss*, 667 F.Supp. 1298 (E.D.Mo.1987). In *Bliss*, one defendant (IPC) had arranged for Bliss, a disposal company, to dispose of certain wastes actually owned and possessed by another defendant (a manufacturer). The court found IPC liable under § 107(a)(3) because:

> IPC acted as a broker between a chemical manufacturer and a disposal company ... IPC had authority to control the place and manner of disposal, for example IPC could have chosen Bliss or any other party to dispose of the waste.

Id. at 1307.

Plaintiffs' authority argument has two flaws. First, both of the cases on which plaintiffs rely to support their position that "authority to control" is the appropriate test for determining whether a defendant constructively owned or possessed waste appear to actually hold that defendants need not own or possess waste at all for liability under CERCLA to attach. In stating it is "authority to control" which is critical, *NEPACCO* cited and relied on *United States v. Mottolo*, 629 F.Supp. 56, 60 (D.N.H.1984), which held a § 107(a)(3) defendant is liable for arranging for disposal regardless of whether he owns or possesses. The *Bliss* court also relied on cases which have held § 107(a)(3) does not require proof that a defendant both arranged and owned or possessed. *See id.* (citing *United States v. Northeastern Pharmaceutical & Chemical Co.*, 579 F.Supp. 823, 847 (W.D.Mo.1984) ("the person arranging for the disposal is not required to actually own or possess the hazardous waste")); *Mottolo*, 629 F.Supp. at 60). A later opinion in the *Bliss* action confirms that *Bliss* held that "[i]t is not necessary for the person who arranges for disposal or transport to own or possess the waste." *United States v. Bliss*, 16 Chem. Waste Lit.Rep. 1061, 1065, 1988 WL 169818, at *6 (E.D.Mo.1988) (citing *NEPACCO*, 810 F.2d at 743).

Second, plaintiffs' argument that 'authority to control' demonstrates constructive possession does not conform with this Court's previous order that constructive possession would be "established by a demonstration of the existence of defendants' exercise of control over the waste." In this particular case, California statutes and case law required defendant cities to provide for solid waste collection. However, if authority to control was sufficient to establish ownership or possession, any government with police power would be liable under § 107(a)(3) so long as it arranged. While a plaintiff would still have to show an arrangement, the authority of the government to control through its police power would automatically satisfy the "owned or possessed" requirement. Focusing on authority to control makes governmental CERCLA defendants potentially liable regardless of their actual exercise of control over waste. Examining defendant cities' exercise of control is the correct means for judging whether defendant cities constructively owned or possessed waste within the meaning of CERCLA § 107(a)(3).

2. Defendant Cities' Exercise of Control

[19] While the municipal defendants' authority to exercise control over waste does not in and of itself demonstrate constructive ownership or possession, their duty to provide for waste disposal is a fact tending to demonstrate exercise of control over waste. *See General Elec. Co. v. AMCO Transmissions, Inc.*, 962 F.2d 281, 286 (2d Cir.1992). California law authorized defendant cities to make adequate provision for solid waste handling and required cities to make such provisions. Defendant cities fulfilled their duty to provide waste collection by hiring transporters to haul away residential and commercial rubbish.

In addition to the municipal defendants' duty to provide for waste collection, plaintiffs point to the control exercised by the cities through contractual provisions and city ordinances while they fulfilled their duty. Plaintiffs organize the stipulated facts into fourteen categories which they urge demonstrate exercise of control over the waste. Through contracts, licenses, and ordinances, the cities:

(1) excluded unauthorized transporters from engaging in waste handling and disposal;

(2) controlled the type of waste to be collected;

(3) controlled the type, size, and construction of waste receptacles;

(4) controlled schedules, routes, days, and hours of collection;

(5) controlled the type, construction, maintenance, and appearance of refuse collection vehicles;

(6) controlled waste handling procedures and personnel;

(7) engaged in overall supervision of waste handling and hauling;

(8) set out procedures for dealing with complaints by residents and businesses about waste collection and hauling;

(9) governed notices and other communications between the transporter and residents and businesses concerning waste collection and hauling;

(10) set rates for refuse collection services;

(11) checked up on the financial stability and reliability of the transporter; and

(12) governed billing and collection of fees for refuse collection services.

Plaintiffs argue that every city exercised control over at least one of these categories in all material years, and that most cities exercised control over all or nearly all of the twelve categories for each year in question through contractual and licensing arrangements.[11]

Defendant cities acknowledge they imposed regulatory requirements on residents, businesses, and disposal companies with respect to waste, but claim there is no evidence that any of the cities ever exercised any control over the waste itself. Plaintiffs correctly respond that control over those in actual possession is the only kind of control which could demonstrate constructive possession of waste. If one does not actually possess the waste, the only means of controlling that waste is controlling the person in actual possession.

Many of the stipulated facts do not show control over the waste. For example, contract specifications requiring disposal workers to wear clean uniforms, disposal trucks painted a uniform color with certain sized letter, and ordinances prescribing route collection times seem to have little to do with control over waste. Some categories of facts,

10. Cal.Pub.Res.Code § 40002 was enacted in 1989. It derived from former Cal.Gov't Code § 66755, which contains nearly identical language and was enacted in 1980.

11. The facts for individual cities are summarized below.

on the other hand, do demonstrate control In arranging with haulers for waste collection and disposal, defendant cities exercised significant control. Essentially, defendant cities did everything but select the specific site for disposal. Each city selected specific haulers to provide collection service to fulfill the city's waste collection responsibility and then extensively regulated those haulers through contract and ordinance.

[20] Defendant cities point to two areas in which they exercised little, if any, control. Specifically, the cities stress that plaintiffs have produced no evidence (1) which suggests any defendant city determined how or where the residential waste was to be dumped once it was collected, or (2) which suggests any defendant city had any proprietary interest in the waste haulers or the disposal of residential and commercial rubbish. Defendant cities claim these two factors are the most important means of determining whether a defendant has exercised the control necessary to make it a constructive owner or possessor.

While defendant cities are correct that prior cases have focused on these two areas, neither the cities' limited involvement in site selection nor their lack of proprietary interest in the haulers compels a finding under the facts of this case that the cities did not constructively own or possess residential and commercial waste.

a. Determining the Place of Disposal

In discussing indicia of control amounting to ownership or possession within the meaning of CERCLA § 107(a)(3), several courts have focused on who decided to deposit waste at the site in question. *E.g., United States v. Consolidated Rail Corp.*, 729 F.Supp. 1461, 1469 (D.Del.1990) ("The inquiry under section 9607(a)(3) turns on the determination of who made the crucial decision to dispose of hazardous substances under the Act, and thus falls within the class of responsible persons"); *United States v. A & F Materials Co.*, 582 F.Supp. 842, 845 (S.D.Ill.1984) ("the relevant inquiry is *who decided* to place the waste into the hands of a particular facility that contains hazardous wastes") (emphasis in original); *see also Hassayampa Steering Comm. v. Cyprus*, 768 F.Supp. 697, 702 (D.Ariz.1991) (constructive ownership or possession "usually evidenced by having the authority to decide on behalf of the owner where the waste would be deposited") (applying nexus test).

The cases cited by defendants, however, focus on the arranger issue and not the owned or possessed issue. *Consolidated Rail* states "liability may also be extended to generators 'who did not make the crucial decision of how [the substances] would be disposed or treated, and by whom,' where '[a]ny other decision would allow defendants to simply 'close their eyes' to the method of disposal of their hazardous substances....'" 729 F.Supp. at 1470 (quoting *United States v. Aceto Agricultural Chem. Corp.*, 699 F.Supp. 1384, 1389 (S.D.Iowa 1988) (alterations in original), *aff'd in part and rev'd in part*, 872 F.2d 1373 (8th Cir. 1989)). *A & F* does not discuss ownership or possession at all because it was not disputed the defendant in that case actually owned the waste.

Evidence that a defendant selected a site for disposal can demonstrate constructive ownership or possession. However, lack of such evidence does not necessarily mean a defendant did not constructively own or possess waste. One of the few cases to mention a defendant's role in deciding where waste was deposited in the context of determining whether that defendant constructively owned or possessed waste is *Hassayampa*, 768 F.Supp. at 702. While *Hassayampa* utilized the nexus test instead of the control test, it is nevertheless instructive. The *Hassayampa* court stated:

> The standard established by prior case law for determining when a non-generator will be constructively held to have owned or possessed the waste requires that the alleged arranger have some nexus with the actual owner, usually evidenced by having the authority to decide on behalf of the owner where the waste would be deposited.

Id. The *Hassayampa* court found the state governmental defendant in that case did not constructively own or possess the waste in question because, *inter alia*, the generator made the determination to transport the waste to the site. *Id.*

There is no evidence in this case to suggest that individuals and businesses that generated the residential and commercial wastes, made a determination to transport waste to OII. Defendant cities disclaim any involvement in site selection, arguing the private disposal companies serendipitously determined where such waste was deposited.

However, the stipulated facts suggest all cities were involved in such decisions to a varying extent. Some cities required haulers to dump waste outside city limits. Some cities knew waste from within their city was being dumped at OII. At least one city, Compton, identified OII as a disposal site available for used by its contractor. In any case, each city selected the hauler who did determine the site and delegated some amount of autonomy over site selection to that transporter.

b. Financial Interest

Defendant cities also argue they did not constructively own or possess residential and commercial waste because they had no proprietary interest in the waste haulers or the disposal of rubbish. According to defendants, Congress intended to impose the cost of cleanup on those who profited from transactions in hazardous waste. Several cases have held this to be an important consideration. *E.g., Lincoln v. Republic Ecology*, 765 F.Supp. at 635-36 ("an unmistakable purpose behind CERCLA's strict liability standard was to force parties who *profit* from the use and generation of hazardous wastes, or directly cause or contribute to their release, to account, in the pricing of their products, for the environmental externalities associated with improper disposal") (emphasis in original); *United States v. New Castle County*, 727 F.Supp. 854, 858 (D.Del.1989) (CERCLA "assures that those who benefit financially from a commercial activity internalize health and environmental costs of that activity into the cost of doing business") (quoting S.Rep. No. 848, 96th Cong., 2d Sess. at 13).

The evidence shows the municipal defendants had no property interest in the haul[illegible] with whom they arranged for disposal [illegible]er, some cities billed residents directly for collection costs. Others received a percentage of the transporter's billings and/or free collection service for governmental waste. Defendant cities who did neither still profited indirectly from contracting with private disposal companies, thus relieving themselves from having to provide collection service.

ii. Nexus Test

Plaintiffs also argue defendant cities constructively owned or possessed residential and commercial waste because of the 'nexus' between defendant cities and the actual owners and possessors of the waste. The nexus test stems from *New York v. City of Johnstown*, which held "there has to be some nexus between the allegedly responsible person and the owner of the hazardous substances before a party can be held liable under 42 U.S.C. § 9607(a)(3)." 701 F.Supp. 33, 36 (N.D.N.Y.1988).

Plaintiffs point out that residential waste and commercial waste was owned or possessed by residents and businesses respectively before the waste was set out for collection. After the waste was hauled away by the disposal company, that waste was owned and possessed by the transporter. Plaintiffs conclude the municipal defendants constructively owned or possessed residential and commercial waste because of the cities' nexus with the generators of residential and commercial waste and/or the transporters of residential and commercial waste, both of whom actually owned or possessed the waste.

1. Nexus with Generators

Plaintiffs claim defendant cities' constructively owned or possessed residential and commercial waste because of their nexus with residents and businesses. As noted above, the 'nexus' test was developed in *Johnstown*, 701 F.Supp. at 36. In *Johnstown*, the state of New York brought suit to remediate problems at two solid waste management facilities. Defendants argued the state was a responsible party under § 107(a)(3) because it "arranged" for disposal by permitting or directing waste to be placed in the facilities. After stating that "there has to be some nexus between the allegedly responsible person and the owner of the ha[illegible]

ardous substances before a party can be held liable" under § 107(a)(3), *id.* at 36, the *Johnstown* court found no nexus existed because the state was attempting to remediate the hazardous waste problems at both sites. *Id.* *Johnstown* distinguished cases which had found defendants constructively owned or possessed as involving either an officer or plant supervisor of a waste-producing corporation or a hired third party who decided how to dispose of the company's waste. *Id.*

The nexus formulation was also used in *United States v. New Castle County*, 727 F.Supp. 854 (D.Del.1989). In *New Castle County*, the state of Delaware was involved in the selection of the site as well as planning its design and operation. The state also determined the type of waste suitable for disposal at the sight. After stating "there must be some nexus or relationship between the person under attack and the actual owner or possessor of the hazardous substance," *id.* at 871, the *New Castle County* court concluded the state of Delaware was not liable because it was attempting to solve the problem of the safe disposal of waste. *Id.*[12]

2. *Nexus with Transporters*

Plaintiffs also argue defendant cities constructively owned or possessed residential and commercial waste because of their nexus with private haulers. Plaintiffs claim the cities' contractual or licensing relationship with transporters was the source of the transporter's possession and ownership of residential and commercial waste. But for the city's approval of the contract or license, the hauler would not be able to transport and dispose of the waste.

In arguing defendant cities' nexus with private haulers made them constructive owners or possessors, plaintiffs rely on a recent Second Circuit decision, *B.F. Goodrich Co. v. Murtha*, 958 F.2d 1192 (2d Cir.1992). The plaintiffs in *Murtha* sought reimbursement for past and future clean up costs from the owner-operators of two landfills. The owner-operator defendants then commenced third party contribution actions against numerous municipalities, alleging the municipalities were liable under § 107 because the cities had arranged for the disposal of municipal waste at the site.

In ruling on an interlocutory appeal from the district court's denial of the cities' summary judgment motion, the court wrote:

> liability under the arranger subsection requires sufficient nexus to be present between the municipality and the hazardous substances, one that does not exist in cases where the governmental unit is responsible only for promulgating disposal regulations or for permitting disposal facilities. Nonetheless, once a sufficient nexus is established (such as, in this case, by managing the disposal activities), the reasons prompting the establishment of that nexus are of no consequence.

Id. at 1199 (citations omitted). Plaintiffs claim defendant cities constructively owned or possessed residential and commercial waste because they too 'managed disposal activities.'

While the *Murtha* opinion does mention what might constitute a "nexus," it actually involved issues decided by this Court back in December, 1990.[13] *See id.* at 1203 (citing Court's December, 1990 order). The *Murtha* opinion addressed three rulings made in the course of the district court's denial of the cities' summary judgment motion. The district court had held:

> that CERCLA does not contain any exemption for municipal waste, and that the exclusion for household solid waste found in the Resource and Recovery Act is not incorporated into the CERCLA definition of hazardous substances. It held further that a municipality disposing of hazardous substances at a site where there is a release or threatened release of such substances may be liable under § 9607 and that plaintiffs had raised genuine issues of material fact as to whether the municipal defendants' waste contained hazardous substances covered by CERCLA.

Id. at 1197.

Thus, the Second Circuit did not examine in *Murtha* the question of whether the cities in that case "owned or possessed" household waste. *Murtha*'s mention of "managing disposal activities" arose in a discussion of a city's immunity for arrangements for disposal of hazardous substances in its sovereign capacity. Fairly read, the *Murtha* decision stated only that plaintiffs could establish a nexus between a city and hazardous substances by introducing evidence on the city's management of disposal activities. The *Murtha* court did not have evidence before it on the interlocutory appeal to reach the "owned or possessed" issue.

To the extent *Murtha* can be read as stating "management of disposal activities" constitutes ownership or possession, its statements are dicta unsupported by factual analysis. In short, defendant cities are correct that *Murtha* did not address the issues presently before the Court and provides little help or guidance in determining whether defendant cities owned or possessed the residential and commercial waste at issue in this action.

The major cases involving governments have all found the governmental entity did not constructively own or possess waste. In *Johnstown*, the court found no owned or possessed nexus even though the state of New York permitted and/or directed waste to placed in the facility. 701 F.Supp. at 36. In *New Castle County*, the court found the state of Delaware did not constructively own or possess waste even though it determined the types of waste permitted to be deposited and approved the disposal of particular wastes at the facility "pursuant to its regulatory and statutory mandate." 727 F.Supp at 874. In *Hassayampa*, the court found the state of Arizona did not constructively own or possess hazardous substances despite the fact that the state notified transporters of the availability of a landfill, issued permits allowing transporters to deposit hazardous waste at that landfill, and assisted in the design of pits into which various types of waste were directed. 768 F.Supp. at 701.

The control exercised by the defendant cities here went beyond that imposed by the defendants in *Johnstown*, *New Castle County*, *Hassayampa*, and *Lincoln*. The municipal defendants contracted with private disposal companies to haul away waste for which they had responsibility and exercised significant control over those haulers through contract and ordinance.

iii. *Conclusion*

1. *Franchises/Contracts*

Taking into account the Court's prior order, the evidence before the Court, and cases already decided under CERCLA, the Court finds defendant cities constructively owned or possessed residential and commercial waste collected under the cities' contracts with private rubbish haulers.

A substantial reason for the Court's conclusion that defendant cities did own or possess is rooted in the California statutes and case law requiring defendants to provide waste collection service. If defendants had provided that service, they clearly would have 'owned or possessed' the waste they collected. CERCLA does not permit defendants to avoid liability by simply hiring an outside contractor to perform collection services instead of the city fulfilling that duty itself. Despite contracting with private disposal companies to perform this function, defendant cities still constructively owned or possessed the waste those companies collected.

In addition to having a duty to provide for disposal service, the stipulated facts discussed below show each defendant city exercised control over residential and commercial waste when it contracted with a transporter. When both duty and control exist, CERCLA § 107(a)(3)'s "owned or possessed" requirement is satisfied.

a. *Alhambra*

From 1960-1984, the Alhambra Athens contracts granted Athens Disposal the exclusive right to collect and dispose of all residential waste. [1-12] During the same time period, the Alhambra Athens contracts

12. Like the court in *Johnstown*, the *New Castle County* court found a nexus does exist where the arranger owned the hazardous substances or where a corporate employee was an arranger. *Id.* at 872 & n. 42.

13. In its December 5, 1990 order, the Court held the Resource and Recovery Act's exemption for household waste did not apply to exempt household waste from CERCLA's definition of hazardous substances.

granted Athens Disposal a non exclusive basis to collect and dispose of refuse from some businesses in Alhambra. [1.4] The Alhambra Athens contracts specified the type of waste to be collected by Athens. [1.39] By ordinance, Alhambra prevented anyone except the city or its agents from removing waste from curbside or alley containers. [1.13] From 1975 1984, the Alhambra-Athens contracts required Athens to report any refuse in violation of the Alhambra Municipal Code, but that the contractor not discuss those violations with members of the public. [1.16] The Alhambra-Athens contracts required Athens immediately clean-up any spills or leaks. [1.29] While Alhambra had no ownership or proprietary interest in Athens [1.40], Alhambra billed and collected fees for refuse collection from residents and some businesses between 1960 and 1984. [1.27] The Alhambra-Athens contracts required Athens to dispose of waste outside city limits, but did not specify a particular site. [1.49] Finally, the Alhambra-Athens contracts required waste collect be done under the direction and to the satisfaction of a designated city employee. [1.51]

b. *Bell*

The Bell System contracts granted System Disposal the exclusive right to collect refuse from all residential dwellings of five units or fewer within the city from 1970 to 1984. [2.6] By ordinance, Bell prohibited anyone from collecting or transporting waste within Bell unless they had a contract or written permit from the city. [2.10] The Bell-System contracts required System Disposal to immediately clean up any spills. [2.20] The Bell-System contracts required System Disposal to provide a full time supervisor satisfactory to the Director of Public Works to supervise the contractor's employees. [2.23] While the Bell-System contracts required System to dispose of all waste outside city limits, the contracts did not specify any site. [2.31; 2.32]

c. *Commerce*

Under the Commerce Cannavo contracts, Commerce granted Cannavo the exclusive right to collect and remove residential waste from 1962 to 1977. [5.9] Under the Commerce-Metropolitan contracts, Commerce granted Metropolitan the exclusive right to collect residential waste from 1977 to 1984. [5.10] Commerce's contracts defined the type of waste to be collected from 1975 to 1984. [5.18][14] While Commerce had no ownership or proprietary interest in Cannavo or Metropolitan, Commerce established the rates for waste collection and paid the waste disposal contractors for refuse collection services performed under the contracts from 1962 until 1984. [5.19; 5.20; 5.40] During that same period, Commerce required that waste collection be under the supervision and to the satisfaction of the city. [5.22] Commerce has stipulated that between 1976 and 1984, its contracts required its waste disposal contractors immediately clean up any spills. [5.32][15] From 1962 until 1977, the Commerce-Cannavo contracts specified that Cannavo was solely responsible for selecting a disposal site located outside city limits for disposal of all waste collected. [5.40]

d. *Compton*

Compton granted Murcole the exclusive right to collect and dispose of residential waste from 1969 to 1984. [6.7] While Compton had no ownership or proprietary interest in Murcole [6.6], Compton established the rates residents were charged for waste collection [6.14] and itself billed and collected waste collection fees from residential units [6.15].

Compton reserved the right to identify and approve the dumpsite(s) used by the city's waste disposal contractor [6.18], and from 1975 through 1984, identified OII as a disposal site available for use by Murcole [6.17]. The Compton-Murcole contracts provided that Murcole's performance would be under the direction and supervision of the City Manager, and that Murcole would obey all orders given by the City Manager with regard to the waste collection and disposal not in conflict with the contracts. [6.31]

14. The parties dispute whether Commerce's contracts defined the type of waste to be collected between [illegible] and 1974

15. The parties dispute whether the contracts so required from 1962 through 1975

e. *Cudahy*

The Cudahy-System contract granted System the exclusive right to collect and dispose of residential waste. [7.5] The Cudahy-System contract prescribed the type of waste to be collected [7.7], and prohibited anyone other than the owner, the city, or the authorized waste collector from removing or transporting waste from a refuse container. [7.6] Although it received no monetary payments from System [7.17] and had no ownership or proprietary interest in System [7.19], Cudahy established maximum monthly rates for residential garbage collection [7.13]. By ordinance, Cudahy specified that all refuse collected within the city be lawfully disposed of in existing public dumps outside the city. [7.22]

f. *Lynwood*

From 1965–1984, Lynwood by ordinance prohibited any authorized person from removing any refuse containers or bins. [12.11] Between 1972 and 1984, Lynwood prohibited the burying of garbage within the city. [12.7] Lynwood established fees for collection and disposal of residential waste and certain commercial pickups between 1972 and 1984. [12.18] Between 1962 and 1978, the Lynwood-CV contracts provided that CV perform the contract under the general supervision of and to the satisfaction of the city manager [12.45], required that CV dispose of all collected refuse at some point outside the city [12.51], and provided that all refuse collected by the waste disposal contractor would become property of the contractor after collection [12.52]. At all relevant times, Lynwood's contracts defined the type of refuse to be collected by the waste disposal contractor. [12.54] Lynwood had no proprietary interest in CV [12.38], but paid CV a monthly fee and then billed and collected fees for residential waste disposal [12.61, 12.65] From 1973-1978, the Lynwood CV contracts required CV to allow city employees to ride with the contractor's crews to supervise their activities [12.75]

g. *Maywood*

By ordinance, Maywood established rates to be charged for waste disposal services between 1961 and 1984. [13.14] During that same time, Maywood defined the type of waste to be collected from within the city. [13.18] Maywood prohibited any person from accumulating garbage on any premises in the city for more than one week. [13.30] From 1957 to 1984, Maywood prohibited by ordinance any person from transporting garbage without a contract or written permission from the city from 1957 until 1984. [13.31] Maywood prohibited disposal upon any public place or vacant premises [13.35] and required waste disposal contractors to disposal of all garbage outside of city limits. [13.40]

h. *Montebello*

From 1952 until 1958, and from 1962 until 1984, Montebello granted certain waste disposal companies the exclusive right to collect residential waste in the city. [14.23] The Montebello–Athens contracts required Athens to dispose of refuse at a place legally empowered to accept garbage for disposal. [14.26] Montebello prescribed the type of waste disposal contractors were to collect [14.41] and the rates for collection service [14.49]. The Montebello–Athens contracts provided that the collection and removal of refuse shall be under the general supervision of the city coordinator from 1963-1972. [14.51] While the Montebello contracts did not specify a disposal site [14.61], the contracts provided that the refuse collected by Athens would become the property of the hauler [14.60] and it is undisputed individuals in the Montebello city government knew waste was being deposited at OII [14.62].

i. *Monterey Park*

Monterey Park granted disposal contractors the exclusive right to collect and dispose of residential waste and a nonexclusive right to collect and dispose of commercial waste. [15.9; 15.10] Monterey Park prescribed the type of waste the waste disposal contractor was to collect [15.25] and established rates for refuse collection service [15.31] From 1970 1984, the Monterey Park contracts required the waste disposal contractor to dispose of refuse at a place legally empowered to accept garbage for disposal. [15.15][16] From 1947 1958, Monterey Park granted

16. The parties dispute whether the contracts so provided from 1960 1969

Harabedian permission to dispose of refuse at OII (subject to obtaining various conditional permits [15.28]). However, the Monterey Park Athens contracts specified Athens was solely responsible for selecting a disposal site [15.44] Monterey Park billed for and collected fees for waste collection services. [15.52] Lastly, the Monterey Park city government knew some waste being collected under its contracts was being deposited at OII. [15.56]

j. *Rosemead*

Rosemead granted its contractor exclusive rights to collect residential waste [18.7] and prescribed the type of waste to be collected by the waste disposal contractor [18.8]. Its contracts require the contractor to collect waste to the satisfaction of a city employee [18.9] and provided that Rosemead would be paid a specific percentage of revenues collected by the contractor [18.20]. By ordinance, Rosemead prohibited any person other than its contractor from collecting or removing waste from residential premises within the city. [18.32] Rosemead also granted disposal companies title to certain waste. [18.35]

k. *San Gabriel*

San Gabriel granted its waste disposal contractors the exclusive right to collect residential waste within the city [19.18] and defined the type of waste to be collected by the contractors. [19.19] While the San Gabriel contracts did not specify the disposal site location for waste collected under the contracts, the contracts did require waste be disposed of outside the city limits. [19.21] San Gabriel established rates for refuse collection services provided by the waste disposal contractors [19.33] and received a percentage of the gross annual receipts collected by the contractor [19.37]. San Gabriel also received free disposal service for its government waste. [19.38]

l. *South Gate*

From 1957 to 1984, South Gate prohibited any person other than the owner, the city, or an authorized collector from removing waste from a waste container [23.13] and prohibited transporting garbage without a contract or written permit from the city [23.10]. At all pertinent times, South Gate prescribed the type of waste to be collected [23.22] and established rates for waste collection service [23.23]. South Gate specified that payments for collection service were to be made to the city. [23.25] The South Gate contracts required waste disposal contractors to collect waste under the supervision of and to the satisfaction of the city engineer. [23.28] The South Gate contracts specified that disposal was to be made at a place devised by the contractor and satisfactory to South Gate. [23.41]

m. *South Pasadena*

South Pasadena granted its haulers an exclusive franchise for the collection of residential and commercial waste in the city. [24.15] The South Pasadena contracts defined the type of waste to be collected. [24.14] The South Pasadena contracts did not specify a site for disposal [24.23], but the South Pasadena city government knew that some of the waste collected was deposited at OII [24.20]. South Pasadena billed its residents and businesses directly for collection [24.33] and retained a specified percentage of the gross collection as a billing and collection fee/franchise fee [24.51]. The contracts required waste collection be performed to the satisfaction of a designated city official. [24.34; 24.51]

n. *Temple City*

Temple City granted Community the exclusive right to collect residential waste [25.9] and defined the type of waste to be collected [25.13]. By ordinance, Temple City prevented any person from collecting or transporting refuse in the city without obtaining a license or contract from Temple City [25.11] and established requirements concerning the maximum period of time that refuse could be stored or accumulated [25.22]. Temple City required the waste disposal companies to pay a monthly fee to the city in consideration for being granted an exclusive contract for the collection of residential waste. [25.36] These facts, among others, demonstrate that each of the above cities, which had a duty to provide for waste collection and exercised control over commercial and/or residential waste and while fulfilling that duty, constructively owned or possessed the residential and commercial waste for which it arranged for transport for disposal by contract. This finding as to the cities of Bell, Commerce, Compton, Cudahy, and Monterey Park relates only to residential waste.

2. *Licenses*

[21] While those defendants who arranged for transport for disposal of commercial waste through licenses had the same duty to provide for waste disposal service, the stipulated facts do not show the same extent of control over waste. The Court concludes plaintiffs have not shown by a preponderance of the stipulated facts that defendant cities constructively possessed waste for which they arranged disposal through licenses. Most of the stipulated facts discuss defendants' contractual arrangements, not their licensing arrangements. For example, plaintiffs' owned or possessed evidence with regard to Commerce relates to Commerce's contracts with private haulers, not its licensing arrangements. Because defendants' duty to provide for collection in and of itself does not suffice for constructive possession, plaintiffs must provide additional evidence showing control by the licensing defendants.

3. *The County Defendants*

a. *Actual Possession*

[22] Each County defendant admits it owned and possessed waste generated by the County. The County has stipulated that some of the waste it generated was disposed of at OII between 1958 and 1981 (although it has not stipulated its waste went to OII in each year between 1958 and 1981). Thus, the County admits waste it owned and possessed was sent to OII during this time frame. Accordingly, the Court finds the County defendants actually owned and possessed County governmental waste.

b. *Constructive Possession*

Plaintiffs and the County defendants make basically same arguments concerning constructive ownership or possession as the arguments of plaintiffs and defendant cities discussed above. While the County defendants do make one additional argument, discussed below, it is not persuasive. Based on the stipulated facts, the Court finds each County defendant constructively owned or possessed residential and commercial waste.

i. *Independent Contractor Argument*

[23] The County defendants argue the disposal companies with whom they contracted were independent contractors. The County defendants claim they did not constructively own or possess residential and commercial waste because the disposal companies, as independent contractors, were not within the control of the County defendants when those haulers deposited waste at OII.

There is no statutory or CERCLA case law support for the County defendants' position and at least one court, *United States v. Bliss*, 16 Chem.Waste Lit.Rep. 1061, 1065–66, 1988 WL 169818, at *6 (E.D.Mo.1988), has rejected that argument. Section 107(b) (which sets forth all defenses available in a § 107(a) action) provides that a person shall not be held liable under § 107(a) if a release was caused solely by the act or omission of a third party. In *Bliss*, the court noted § 107(b) further provides that this third party defense is not available when the acts or omissions of the third party "occur[ ] in connections with a contractual relationship, existing directly or indirectly with the defendant." CERCLA § 107(b)(3); 42 U.S.C. § 9607(b)(3).

Even if the disposal companies hired by the GDDs were independent contractors, that fact does not affect the possible liability of the County defendants under CERCLA. As pointed out in *Bliss*, the structure of CERCLA rejects the County defendants' independent contractor argument. Section 107(a) imposes liability on those who arrange for disposal through "contract, agreement, or otherwise." Creating an exemption for independent contractors would eviscerate § 107(a)(3) by placing many contractual arrangements outside that section's "contract, agreement, or otherwise" language.

ii. *Summary of Evidence*

The GDDs and County had a duty to provide for waste disposal, and fulfilled that duty by contracting with haulers for transport for disposal. Each GDD granted haulers an exclusive right to collect all garbage

and combustible and non combustible rubbish. Each required its hauler to dispose of waste outside the geographical boundaries of the GDD. The contracts between the GDDs and their haulers required performance under direction of and to the satisfaction of a designated county employee. The GDDs billed residents for collection services and property owners paid their fees for refuse collection to the Los Angeles County Treasurer. Each GDD sometimes received more revenue from property owners than they paid out for collection service. When this occurred, the money was used to pay for waste collection in later years.

Because the one additional argument raised by the County defendants is unpersuasive, the Court finds each County defendant constructively "owned or possessed" the residential and commercial waste for which it arranged for transport for disposal within the meaning of CERCLA § 107(a)(3).

4. *CalTrans*

CalTrans claims it did not own or possess the material removed from the Willco site and the Pomona Freeway right-of-way within the meaning of § 107(a)(3). Plaintiffs claim CalTrans has already stipulated it actually owned and actually possessed the material removed from the Willco site and the Pomona freeway right-of-way.

i. *The Contract Governing the Willco Site*

[24] The parties have stipulated that in 1983 CalTrans owned the Willco site and the material found there. [33.5] However, under the contract governing the Willco site excavation, the excavated Willco material became the property of the contractor, Papac & Sons. [33.6] While CalTrans may have originally owned the material, title passed to Papac & Sons when the material was removed from the site. CalTrans thus claims it did not own or possess the material within the meaning of CERCLA § 107(a)(3) because the contract provided that Papac & Sons, who possessed the material once it was excavated, owned the material.

The Court finds CalTrans owned or possessed the Willco material within the meaning of CERCLA § 107(a)(3). Section 107(a)(3) imposes liability on any person who "arranged with a transporter for transport for disposal or treatment, of hazardous substances owned or possessed by such person." At the time CalTrans arranged for transport for disposal, it did own the Willco site material. The sole fact that title subsequently passed to the transporter does not absolve CalTrans of potential liability.

ii. *Pomona Freeway Right Of Way*

[25] CalTrans has stipulated that it acquired a portion of the OII site in the 1950s to use as a right of way for the Pomona Freeway. [33.13] CalTrans argues it cannot be held liable as an owner of the Pomona Freeway right of way material because it acquired title by eminent domain.[17]

CalTrans obtained title to both the Willco and Pomona Freeway sites by eminent domain. Section 101(20)(D) of CERCLA states:

> The term "owner or operator" does not include a unit of State or local government which acquired ownership or control involuntarily through bankruptcy, tax delinquency, abandonment, or other circumstances in which the government involuntarily acquires title by virtue of its function as sovereign. The exclusion provided under this paragraph shall not apply to any State or local government which has caused or contributed to the release or threatened release of a hazardous substance from the facility.

42 U.S.C. § 9601(20)(D). CalTrans claims this provision of CERCLA exempts it from liability based on its having "owned or possessed" because its acquisition of the Willco and Pomona material through eminent domain was 'involuntary' under § 101(20(D).

Section 101(20)(D) contains the statutory definition of the term "owner or operator," as in owner or operator of a facility for disposal liable under § 107(a)(1). Section 101(20)(D) prevents a governmental entity from being held liable when it involuntarily inherits a waste facility. It does not prevent CalTrans for being held liable for acquiring land through eminent domain and then arranging

17. CalTrans makes this same argument with respect to the Willco material

to have material on that land transported for disposal.

The Court finds CalTrans owned or possessed the Pomona Freeway right of way material. However, plaintiffs still must show CalTrans arranged with a transport for transport for disposal of this material.

D. *Whether Waste Went to the Site*

As summarized below, most of the parties have stipulated that some waste collected under the various contracts and licenses at issue in the action was disposed of at the OII site.

1. *Municipal Defendants*

a. *Alhambra*

During the period October, 1960 through 1984, Athens Disposal disposed of some residential waste, some commercial waste, and some of the governmental waste collected in the City of Alhambra under its contracts with the city. [1.9-1.11] However, the parties have not stipulated to any specific time frame during that period when those waste streams were disposed of at OII.

b. *Bell*

During the period August, 1970 through December, 1984, System Disposal disposed of some residential waste collected under its contractual arrangement with Bell. [2.36] However, the parties have not stipulated to any specific years within that time frame when residential waste from Bell was disposed of at OII.

c. *Commerce*

Plaintiffs and defendant City of Commerce have not stipulated to any residential, commercial, or governmental refuse from Commerce being disposed of at the OII site.

d. *Compton*

Between 1969 and 1984, Murcole disposed of some of the residential waste and some of the governmental waste collected under its contracts with Compton at the OII site [6.63, 6.66] During the period March, 1969 through June, 1977, Murcole also disposed of some of the commercial waste collected under its license from Compton at OII [6.64] These stipulations are not specific as to years.

e. *Cudahy*

From October, 1981 through December, 1984, System Disposal disposed of some of the residential waste collected under its contract with Cudahy. [7.33] This stipulation is not specific as to years.

f. *Lynwood*

Between 1962 and 1984, CV Disposal disposed of some of the residential waste collected under its contracts with Lynwood at the OII site. [12.31] This stipulation is not specific to years.

g. *Maywood*

From December, 1972 through 1984, System Disposal disposed of some of the residential waste collect under its contracts with Maywood. [13.56] This stipulation is not specific as to years.

h. *Montebello*

From February 1952 through 1958, Harabedian and Slater disposed of some of the residential waste collected under their contract with Montebello at the OII site. [14.15] During the period October 1962 through 1984, Athens Disposal disposed of some of the residential waste and some of the commercial waste collected under its contracts with Montebello. [14.18; 14.19] These stipulations are not specific as to years.

i. *Monterey Park*

Between 1947 and 1958, Harabedian disposed of some of the residential waste collected under his contracts with Monterey Park at the OII site. [15.62] During the period July 1960 through January 1970, CV Disposal disposed of some of the residential waste it collected under its contract with Monterey Park at the OII site. [15.63] Between January, 1970 and 1984, Athens Disposal disposed of some of the residential waste and some of the governmental waste collected under its contractual arrangement with Monterey Park at the OII site [15.64; 15.68] During the period 1960 through 1984, Athens Disposal disposed of some of the commercial waste collected under its contractual arrangement with Monterey Park. [15.65] Monterey Park itself disposed of

some of its governmental waste collected and transported in city vehicles at OII. [16.69] None of these stipulations are specific as to years.

j. *Rosemead*

Between 1961 and 1981, Griegorian/Modern disposed of some of the residential waste collected under its contracts with Rosemead at the OII site. [18.38] Between 1965 and 1981, Griegorian/Modern also disposed of some of the commercial waste collected under its contracts with Rosemead. [18.39] These stipulations are not specific as to years.

k. *San Gabriel*

During the period December 1957 to March, 1964, Community Disposal Co. disposed of some of the residential waste and some of the commercial waste collected under its contracts with San Gabriel. [19.16] This stipulation is not specific as to years.

l. *South Gate*

Between December, 1967 and December, 1984, CV Disposal disposed of some of the residential waste collected under its contractual arrangement with South Gate. [23.65] This stipulation is not specific as to years.

m. *South Pasadena*

Between 1950 and 1969, South Pasadena Disposal disposed of some of the residential waste and some of the commercial waste collected under its contracts with South Pasadena. [21.9; 24.10] During the period 1979 through 1984, Romra disposed of some of the residential waste and some of the commercial waste collected under its contracts with South Pasadena. [24.12] These stipulations are not specific as to years.

n. *Temple City*

Between 1960 and 1982, Community disposed of some of the residential waste and some of the commercial waste collected under its contracts with Temple City. [25.6; 25.7] This stipulation is not specific as to years.

2. *County Defendants*

All of the County defendants except the Walnut Park GDD have stipulated that waste from the GDD or County was deposited at OII.

a. *Athens Woodcrest-Olivita GDD*

The Athens Woodcrest Olivita GDD has stipulated that during the period January 1970 through 1984, the G.K. Companies disposed of some of the waste collected under its contracts with the GDD at the OII site. [26.8]

b. *Belvedere GDD*

Between 1970 and 1977, Holthe Disposal disposed of some of the waste it collected under its contract with the Belvedere GDD at the OII site. [27.16] During the period April 1, 1977 through June 30, 1983 System Disposal disposed of some of the waste it collected under its contract with the Belvedere GDD at the OII site. [27.18]

c. *Firestone GDD*

Between January 1971 and 1984, Universal disposed of some of the waste collected under its contracts with the Firestone GDD at the OII site. [28.6]

d. *Mesa Heights GDD*

During the period 1970 through 1974, Holthe Disposal disposed of some of the waste collected under its contracts with the Mesa Heights GDD at OII. [29.6]

e. *Walnut Park GDD*

Defendant Walnut Park GDD and plaintiffs have not reached any stipulation regarding waste disposal at the OII site.

f. *Los Angeles County*

Documentary evidence such as deposit tickets and other accounting records show that during the period 1958 through September, 1981, the County itself disposed of some County governmental waste at the OII site by transporting the waste to OII in County vehicles. [32.33]

3. *CalTrans* *

a. *Willco Site*

CalTrans has stipulated that Papac & Sons deposited some of the Willco material at the OII site during the period from March, 1983 to June 30, 1983. [33.4]

b. *Pomona Freeway Right of Way*

CalTrans and plaintiffs have not reached any stipulation regarding whether or not excavated Pomona material was taken to the OII site.

III. CONCLUSION

A. *Issues Submitted for Pre-Trial Legal Determination*

1. *Do Plaintiffs Have Standing To Sue For Cost Recovery Under CERCLA § 107 or Are They Limited to Remedies For Contribution Under CERCLA § 113(f)?*

Both the language of the statute and equitable consideration lead to the conclusion that plaintiffs may bring this action under § 107(a). Accordingly, the Court finds that plaintiffs have standing to sue for cost recovery under § 107(a)(3).

2. *Do Considerations of Public Policy and a Due Regard For the Sovereign Power of a City to Protect the Public Health, Safety, and Welfare Preclude Imposition of Liability in this Case?*

Neither public policy considerations nor a due regard for a city's sovereign power to protect the public health, safety, and welfare preclude imposition of liability in this action. Defendants' sovereign power defense is no defense to potential CERCLA liability in this case.

3. *Joint and Several Liability*

Although the parties, to one degree or another, have submitted this issue for pretrial determination, the Court cannot give a final answer to this question before trial. Joint and several liability is available under CERCLA, but its availability depends of the severability of the harm. Individual defendants may be entitled to joint and several liability if they can show the harm they caused is divisible. The Court declines to rule on the question of divisibility because that issue is not yet ready for determination.

4. *Does the Doctrine of De Minimus Non Curat Lex Absolve Defendants From Liability?*

Given that plaintiffs can sue under § 107, the doctrine of 'de minimus non curat lex' cannot be asserted as a defense.

B. *Are Defendants 'Arrangers,' And If So, For What Years?*

1. *The Municipal Defendants*

Under the legal standards established by the Court's September, 1991 Order, each municipal defendant "arranged" within the meaning of CERCLA § 107(a)(3). Each either contracted with a disposal company/transporter or licensed haulers to provide for transport for disposal of specific waste streams for the years discussed in the body of this order.

2. *The County Defendants*

All of the GDDs qualify as arrangers within the meaning of CERCLA § 107(a)(3). As for the County itself, it also arranged for transport for disposal within the meaning of CERCLA § 107(a)(3) by establishing and maintaining the GDDs.

3. *CalTrans*

CalTrans was an arranger with respect to the material excavated from the Willco site. With respect to the material excavated from the Pomona Freeway right of way, plaintiffs have not shown sufficient facts to justify a finding that CalTrans arranged within the meaning of CERCLA § 107(a)(3).

C. *Did Defendants "Own or Possess" the Waste For Which It Arranged Disposal, And If So, For What Years?*

1. *The Municipal Defendants*

Defendant cities do not dispute they actually owned and possessed their governmental waste during the relative time periods. Furthermore, defendant cities constructively owned or possessed residential and commercial waste collected under contractual arrangements. With regard to those defendants who arranged by license, plaintiffs must introduce additional facts evincing control over the waste.

2. *The County Defendants*

Both plaintiffs and the County defendants agree the County defendants actually owned and possessed government waste. The Court additionally finds the County defendants constructively owned or possessed residential or commercial waste.

3. *CalTrans*

The Court finds CalTrans owned and possessed the material excavated from both the Willco site and the Pomona Freeway right of way within the meaning of CERCLA § 107(a)(3). Although title may have passed to the actual excavator, the language of the statute covers situations in which the defendants arranges for transport for disposal while he owns the material and then subsequently passes on title.

D. *Was At Least Some of the Waste 'Owned or Possessed' by Defendants For Which Defendants Arranged Disposal, Disposed of At OII?*

The stipulated facts reveal that some waste, be it residential, commercial, or governmental, was deposited at the OII site at some relevant time frame with regard to all defendants except the City of Commerce, the Walnut Park GDD, and CalTrans (with regard to the Pomona material). Plaintiffs have shown only that some waste at some relevant time was deposited at OII. Plaintiffs will have to provide more exact proof on this issue in later phases of the action.

Upon completion of all proceedings in this matter, the Court will expand upon this order and file final Findings of Fact and Conclusions of Law or a final memorandum order.

AMERICAN STATES INSURANCE CO., Plaintiff,

v.

SACRAMENTO PLATING, INC., et al., Defendants.

No. Civ. S-93-0569-WBS/PAN.

United States District Court, E.D. California.

Aug. 29, 1994.

Insurer brought action against property owners and operators of metal electroplating facility, seeking declaration that comprehensive general liability policies did not cover cleanup costs resulting from soil contamination below facility. On insurer's motion for summary judgment, the District Court, Shubb, J., held that under California law, contamination did not fall within "sudden and accidental" exception to pollution exclusions in comprehensive general liability insurance policies, notwithstanding evidence of three large spills.

Motion granted.

1. Insurance ⇐137.1(1)

Under California law, insured had burden to prove that "sudden and accidental" exception to pollution exclusion in comprehensive general liability insurance policies applied.

2. Insurance ⇐137(1)

Under California law, contamination of soil below metal electroplating facility did not fall within "sudden and accidental" exception to pollution exclusions in comprehensive general liability insurance policies, notwithstanding evidence of three large spills; spills were not "sudden and accidental," as they were not unexpected, there was no evidence that soil contamination was caused by the spills, and even if they did cause some soil contamination, they only contributed to contamination caused by pollution occurring in regular course of plating operation.

See publication Words and Phrases for other judicial constructions and definitions.

3. Federal Civil Procedure ⇐2515

Litigant objecting to admission of expert's deposition testimony in summary judgment context on ground that there were insufficient foundational facts regarding expert's qualifications and as to scientific methods used to reach his conclusions could not prevail in light of litigant's failure to provide court with any portions of deposition which would call into question either witness' qualifications or bases of his opinions, counsel for litigant had had opportunity to cross examine expert on both his qualifications and methods used to reach his opinion. Fed.Rules Evid. Rule 705, 28 U.S.C.A.

4. Federal Civil Procedure ⇐2515

In considering motion for summary judgment, court had broad discretion in ruling upon admissibility of expert testimony.

Martha S. Hollingsworth, Bingham Summers Welsh and Spilman, Indianapolis, IN, Craig Edward Farmer, Farmer and Murphy, Rancho Cordova, CA, for American States Ins. Co.

Richard Perry, pro se.

Daniel William Smith, Hefner Stark and Marois, Sacramento, CA, for Arthur LaBour.

Craig C. Allison, Downey Brand Seymour and Rohwer, Sacramento, CA, for Alice Kazanjian.

Alice Kazanjian, pro se.

Edwin B. Medlin, Ropers Majeski Kohn Bentley Wagner and Kane, Redwood City, CA, Craig Edward Farmer, Farmer and Murphy, Rancho Cordova, CA, for Royal Ins. Co. of America.

Daniel William Smith, Hefner Stark and Marois, Sacramento, CA, for Arthur LaBour.

MEMORANDUM AND ORDER

SHUBB, District Judge.

American States Insurance Company ("ASI") brought this action seeking a declaration that certain ASI comprehensive general liability ("CGL") policies do not cover clean-up costs resulting from the contamination of soil below a Sacramento metal electroplating facility. The defendants are the property owners and the operators of the facility.

ASI has filed a motion for summary judgment on its claim for declaratory relief and on defendant Arthur LaBour's counterclaims. Only LaBour, the current property owner, filed a memorandum in opposition to ASI's motion. Because the court finds that the pollution exclusions contained in ASI's policies preclude coverage, the motion for summary judgment will be granted.

I. FACTUAL AND PROCEDURAL BACKGROUND

A. The Parties and the Property

The dispute centers on four parcels of property located on "S" Street in Sacramento, California. On one parcel, located at 2809 "S" Street, was an industrial electroplating facility. In 1963, defendants Richard and Arlene Perry ("Perry") entered into a contract to purchase the property from defendant Alice Kazanjian. In February 1972, title was transferred from Kazanjian to Perry.

From 1963 to 1988, Perry, the former owner and general manager of Sacramento Plating, Inc. ("SPI"), operated the electroplating facility. During that time, Richard Perry "was physically at the site watching and participating in the electroplating processes on a full-time daily basis...." Perry Decl. ¶ 5.

LaBour purchased the property from Perry in January 1981. After purchasing the property, LaBour leased it back to Perry until October 1989. LaBour is the present owner of the property.

B. The ASI Policies

ASI issued CGL policies covering Perry/SPI and LaBour for different periods of time during SPI's operation at the "S" Street site. ASI issued two policies to Perry/SPI for two one-year periods between March 6, 1981 and March 6, 1986 (hereinafter "S1" and "S2"). ASI may have issued a third one-year policy covering the period of time between March 6, 1986 and March 6, 1987 (hereinafter "S3").[1]

ASI issued LaBour a total of three CGL policies. The first two policies covered two one year time periods from March 23, 1984 to March 23, 1986 (hereinafter "L1" and "L2"). The third policy period began March 23, 1986, but was cancelled effective May 21, 1986 (hereinafter "L3").

1. The parties agree that the policy may have been issued, but that it cannot, at present, be located

Waste Management & Research (1993) 11, 257–268

A REVIEW OF RECENT STUDIES ON THE SOURCES OF HAZARDOUS COMPOUNDS EMITTED FROM SOLID WASTE LANDFILLS: A U.S. EXPERIENCE

Debra R. Reinhart

Civil and Environmental Engineering Department, University of Central Florida, Orlando, Florida 32816-4450, U.S.A.

(Received 18 March 1992, accepted in revised form 7 September 1992)

Municipal solid waste landfills operating in the United States receive a large variety of materials generated by an industrialized, "throwaway" society. As a result, liquid and gas emissions (produced during the normal decomposition processes occurring within the landfill) are often contaminated with hazardous compounds. The presence of hazardous pollutants in liquid and gaseous emissions is well documented, however, the source of these pollutants is not always apparent. Potential sources of these hazardous contaminants in municipal solid waste landfills may include small quantity generators of hazardous wastes, household hazardous wastes, wastes disposed prior to the 1980 enactment of U.S. hazardous waste disposal legislation, and biological and chemical transformation products of buried refuse. Source identification will facilitate characterization and quantification of emissions necessary for the design and operation of leachate gas collection and treatment facilities.

Key Words—Leachate, solid waste, biogas, hazardous wastes, refuse, landfills, waste management, landfill emissions, waste disposal, waste characterization, U.S.A., state-of-art review.

1. Introduction

In 1988, 163 million tonnes of municipal solid waste (MSW) were generated in the United States (Franklin Associates Ltd 1990). Approximately 73% of this material was placed in over 6000 MSW landfills. Recycling and solid waste combustion will play increasingly important roles in future integrated waste management; however, projections show that dependence on landfilling for disposal of a significant portion of MSW will continue long into the future.

Once solid waste is placed in a landfill, a complex sequence of biologically, chemically and physically-mediated events occur which result in gaseous and liquid emissions. Leachate is produced as water percolates through the solid waste, leaching soluble components and degradation products from the refuse. Landfill gas is generated during stabilization of solid waste organic fractions. Volatile components of the buried solid waste tend to be transported out of the landfill with the evolving gas stream. Due to the long-term potential for production of contaminated gas and leachate, proposed U.S. federal landfill regulations call for monitoring of groundwater and landfill gas for 30 years (USEPA 1988*a*).

The contamination of groundwater by landfill leachates has been recognized by a variety of researchers (Reinhard *et al.* 1984, Schultz & Kjeldsen 1986, Sawney & Kozloski 1984). Organic chemicals found in 58 municipal and industrial landfills

0734-242X 93 030257 + 12 $08.00 0 © 1993 ISWA

represented a broad range of chemicals with significant genotoxic potential (Brown & Donnelly 1988). Several researchers have found leachate to be quite toxic to rainbow trout and daphnia (Cameron & Koch 1980, Atwater *et al.* 1983) and to have some toxicological impact on laboratory mice (Raddi *et al.* 1987). In addition, some 22% of the sites placed on the U.S. National Priority List for hazardous waste site cleanup are closed municipal landfills (Repa 1988).

Approximately 200,000 tonnes of volatile organic compounds (excluding methane) are released from MSW landfills each year, including both odor nuisance and hazardous pollutants (USEPA 1988*a*). Unites States Environmental Protection Agency (USEPA) risk analysis of MSW landfill uncontroled gas emissions showed the risk of excess cancer incidents to be 100 to 10,000 per million exposed individuals (Minott 1989).

The sources of these gaseous and liquid hazardous contaminants include household hazardous wastes, illegally disposed regulated hazardous wastes, waste disposed by small quantity hazardous waste generators, hazardous wastes disposed of prior to enactment of hazardous waste regulations and otherwise innocuous wastes transformed during normal stabilization processes. These sources will be described in detail herein. It is anticipated that source identification will facilitate quantification, characterization and control of hazardous emissions from MSW landfills.

2. Leachate and gas characterization

As water passes through a landfill, contaminants are leached from the solid waste. Mechanisms of contaminant removal include leaching of inherently soluble materials, leaching of soluble products of chemical or biological reactions and washout of fines and colloids (Crawford 1985). The characteristics of the leachate are highly variable depending on the composition of the solid waste, rate of water application, refuse moisture content, and landfill design, operation and age (Pohland & Harper 1985).

2.1 Organic contaminants of leachate

Organic contaminants of leachate are primarily soluble refuse components of decomposition products of biodegradable fractions of municipal refuse. Organic compounds detected in 19 MSW landfill leachates or contaminated groundwater plumes included organic acids, ketones, aromatic compounds, chlorinated aromatic compounds, ethers, phthalates, halogenated aliphatic compounds, alcohols, aminoaromatic compounds, nitroaromatic compounds, phenols, heterocyclic compounds, pesticides, sulfur-substituted aromatic compounds, polyaromatic hydrocarbons, polychlorinated biphenyls and organophosphates (Brown & Donnelly 1988).

The class of organic compounds found at highest concentration in leachates is generally volatile fatty acids produced during the decomposition of lipids, proteins and carbohydrates (Albaiges *et al.* 1986, Schultz & Kjeldsen 1986). Aromatic hydrocarbons, including benzene, various xylenes and toluene, are also frequently found at lower concentrations (Schultz & Kjeldsen 1986, Harmsen 1983). These compounds were considered to be constituents of gasoline and fuel oils. Sawney & Kozloski (1984) reported that the presence of the more soluble, less volatile aromatic components of gasoline suggested that the more volatile components were being gas stripped from the landfill. Non-volatile classes of compounds such as phenolic compounds may be degradation byproducts of lignin. A small complex fraction found in several leachates contained nicotine, caffeine and phthalate plasticizers (Albaiges *et al.* 1986).

2.2 Heavy metals

A variety of heavy metals are frequently found in landfill leachates including zinc, copper, cadmium, lead, nickel, chromium and mercury. In several instances heavy metal concentrations in leachate exceed U.S. toxicity characteristic leaching procedures standards (Lu *et al.* 1985).

Heavy metal concentrations in leachate do not appear to follow patterns of organic indicators such as chemical oxygen demand (COD) or biochemical oxygen demand (BOD), nutrients or major ions (Lu *et al.* 1985). Heavy metal release is a function of characteristics of the leachate such as pH, flow rate and concentration of complexing agents.

2.3 Landfill gas

During solid waste stabilization significant portions of organic wastes are ultimately converted to gaseous end-products. The rate of gas production is a function of refuse composition, climate, moisture content, particle size and compaction, nutrient availability and buffering capacity. Reported production rates vary from 0.12–0.41 cubic meters of gas per kg dry waste (Pohland & Harper 1985). Landfill gas is typically 40–60% methane, with carbon dioxide and trace gases such as hydrogen sulfide, water vapor, hydrogen and various volatile organic compounds comprising the balance.

Because of their high vapor pressures and low solubilities, many toxic volatile organic compounds (VOCs) are observed in landfill gas. In a report by the State of California Air Resources Board (Bennett 1987), the average subsurface emission rate of hazardous chemicals from landfills was estimated to be 35 kg per million kg of refuse. Landfill gas trace constituents include halogenated aliphatics, aromatics, heterocyclic compounds, ketones, aliphatics, terpenes and alcohols, and have been characterized by several researchers (Siu *et al.* 1989, Young & Parker 1983, Wood & Porter 1987, LaRegina & Bozzelli 1986).

3. Source of hazardous pollutants

3.1 Household hazardous wastes

Household hazardous wastes refer to solid wastes discarded from homes or similar sources that, if discarded in significant quantities, would be regulated in the U.S.A. under the Resource Conservation and Recovery Act (RCRA) enacted in 1980. These wastes are either listed by the USEPA in 40 CFR, Parts 261.33 (e) or (f) or exhibit hazardous characteristics of ignitability, corrosivity, reactivity or toxicity as defined in 40 CFR Part 261.24. Despite their hazardous nature, wastes derived from households are exempt from RCRA regulation.

The existence of these wastes is a consequence of the introduction (largely since World War II) of modern convenience products such as cleaning compounds, pesticides, pharmaceuticals, plastics, synthetic textiles and coatings. One consequence of the availability of these products has been the release of hazardous substances during product manufacture, use and/or disposal. Management options for hazardous household wastes primarily include recycling, disposal in public sewers and burial in hazardous or municipal landfills.

Provided in Table 1 is a list of household hazardous wastes which might be found in MSW landfills. Over 100 synthetic organic chemicals are present in household products as well as a variety of potentially toxic heavy metals. The more common and most toxic

TABLE 1

household hazardous wastes include pesticides, paints, household cleaners and automotive products. Pesticide wastes are potential sources of chlorinated organic compounds, carbamates and organophosphates. Paint solvents include toluene, 1, 1, 1-trichloroethane, tetrachloroethene, alcohols, ketones, esters and petroleum distillates. Wood preservatives may be the source of chlorinated phenols and creosote. Household cleaners are composed of a mixture of complex synthetic compounds and may include chlorinated phenolic compounds (disinfectants), acids and bases (such as hydrochloric acid, sodium hydroxide, oxalic acid and sodium hypochlorite), dichlorobenzene (mothballs), glycols (antifreeze, disinfectants, cleaners), various surfactants (detergents, wetting agents, air fresheners), chelating agents and propellants (including isobutane, dichlorodifluoromethane, propane, trichlorotrifluoroethane and methylene chloride).

Several surveys have attempted to quantify and characterize household hazardous wastes. In 1984, the Los Angeles County Sanitation District sorted 3500 loads containing approximately 13,608 tonnes of MSW. From their studies, it was estimated that household hazardous wastes accounted for 0.00147% of the total municipal waste (Commonwealth of Virginia n.d.). The University of Arizona identified 100 containers of hazardous items per household per year in a survey conducted from 1973 through 1986 (Freeman 1989). The City of Albuquerque, New Mexico, examined 726 tonnes of MSW generated by 96,300 households in 1983 and concluded that hazardous wastes constituted less than 0.5% of the wastes (Freeman 1989). During a USEPA study conducted by SCS Engineers at six Michigan counties, a total of 135 tonnes of wastes were sorted over a 1 week period in each of the four seasons. Household hazardous wastes represented between 0.0–0.3% of the wastes, averaging 0.08% (Commonwealth of Virginia n.d.).

An extensive study of nonregulated hazardous wastes in municipal refuse generated in King County, Washington was conducted by Cal Recovery Systems Inc. (1985). This study provided important insights into the characteristics and sources of these wastes.

The King County study identified four potential sources of nonregulated wastes: residential, commercial, industrial and self-haul. Two types of samples were collected and analysed, discrete samples (cans, bottles, boxes) and dispersed samples, to identify hazardous substances which had been dispersed throughout the wastes. A total of 30.6 tonnes of wastes were examined.

Batteries were found to be the largest source of lead in King County. Mercury was found in thermostats, paints and containers from medical or dental clinics. Chromium and barium were detected in paints. The sources of several volatile organic compounds were identified as paints, solvents and, to a lesser extent, adhesives, pesticides, aerosols, cosmetics and furniture wax. Pesticides were discarded as specific products but also detected in paints as fungicides. The source of several heavy hydrocarbons was found to be oil and grease waste, while polyaromatic hydrocarbons and other simple aromatic compounds were detected in discarded roofing materials.

3.2 Small quantity generators

The 1980 amendments to RCRA set forth requirements for regulation of the transportation, storage, treatment and disposal of hazardous wastes in the U.S. Recognizing the limitations of the regulatory community, the U.S. Congress exempted small quantity generators (SQG) from most hazardous waste regulations. SQGs are defined as generating less than 1000 kg of hazardous waste in a calendar month. The 1984 Hazardous and Solid Waste Amendments to RCRA expanded the universe of regulated generators by identifying conditionally exempt SQGs (CESGQ) as those generating less than 100 kg of hazardous waste in a calendar month. As of 22 September 1986, those SQGs generating between 100–1000 kg of hazardous waste per month were required to meet most of the key requirements of the RCRA program, including use of permitted hazardous waste treatment and disposal facilities. In a 1984 study, USEPA estimated that there were between 600,000 and 660,000 small quantity generators of hazardous wastes in the U.S. (Abt Associates Inc. 1985). Some estimates put this number closer to 1,000,000 (Schwartz & Pratt 1990). These SQGs accounted for approximately 98% of the nation's hazardous waste generators, but contributed less than 0.4% of the hazardous waste generated. CESQGs represented 72% of the SQGs while generating less than 20% of the SQG hazardous waste. In 1985 it was estimated that approximately 940,000 tonnes of hazardous waste were generated by SQGs, of which approximately 825,760 tonnes were placed in MSW landfills (Abt Associates, Inc. 1985). This represents less than 1% of the waste disposed of in MSW landfills each year. With the promulgation of the regulations exempting only CESQGs, it is estimated that approximately 0.08% of the waste disposed of in MSW landfills is presently generated by SQGs (Carra & Coussu 1990).

SQG wastes may be potential sources of pesticides, heavy metals, acids, bases, oils and other petroleum derived materials and solvents. A recent Florida study identified 26 categories of SQGs generating a total of 117,042 tonnes (Herndon & Moerlins 1988). Approximately 26,762 tonnes of this material were placed in MSW landfills, representing about 0.2% of the total waste disposed. A breakdown of SQG hazardous wastes by type placed in Florida MSW landfills is provided in Table 2.

3.3 Illegal disposal

Improper management of hazardous wastes routinely occurs, as documented by the increasing frequency of state and federal enforcement actions against industrial firms

TABLE 2
Hazardous waste disposed in Florida sanitary landfills annually*

Waste type	% of total
Waste pesticides	0.15
Washing solutions	0.28
Empty pesticide containers	1.08
Spent solutions from dipping	0.00
Other pesticide solutions	0.09
Dust with heavy metals	3.72
Rinses with heavy metals	3.45
Sludges with heavy metals	4.92
Waste ink	0.47
Ignitable paint waste	1.89

Waste oils, lubricants	45.22
Other	5.87
Total	100

* From Herndon & Moerlins (1988).

convicted of such practice. Illegal disposal of hazardous wastes by SQGs is particularly prevalent. Waste management facility personnel estimate that from 30–50% (and perhaps as high as 90%) of SQGs may illegally dispose of their wastes (Schwartz & Pratt 1990). A study in Larimer County, Colorado, found that 90% of hazardous wastes generated by SQGs was improperly disposed of in sewers, septic tanks, vacant lots and MSW landfills, potentially resulting in the uncontroled release of hazardous substances to the environment. Illegal disposal can be attributed to uninformed generators, minimal enforcement of regulations and/or the high cost of proper hazardous waste management.

3.4 Disposed prior to hazardous waste regulation

A 1973 study of hazardous waste management in the U.S. concluded that the vast majority of hazardous wastes were improperly disposed (Dawson & Mercer 1986). Improper management included the disposal of hazardous wastes into landfills without bottom liners, leachate collection and treatment, or proper gas management and located in environmentally sensitive areas. One consequence of such disposal is the placement of

184 MSW landfills on the National Priority List (NPL) of the most severely contaminated uncontroled hazardous waste sites in the U.S. (Repa 1988). This represents approximately 22% of the NPL sites. All of the MSW landfills on the NPL were operated prior to the enactment of legislation regulating hazardous waste disposal and are presently closed. Only 1% of these landfills accepted exclusively MSWs. Approximately 84% of these sites reported releases to groundwater, 51% to surface water and 18% to the air. Pollutants released included halogenated organic compounds, aromatic compounds, metals, volatile organic compounds, pesticides and asbestos.

A recent study evaluated leachate data from 111 landfills with the objective of comparing releases of hazardous pollutants from landfills operated before the 1980 promulgation of hazardous waste regulations and to landfills operated after 1980 (USEPA 1988*b*). Surprisingly, little difference was observed between the concentration or the frequency of detection of inorganic and organic contaminants found in leachates from pre- and post-1980 MSW landfills. However, pre-1980 MSW landfills were found to exceed standards for five or more constituents more often than post-1980 landfills.

3.5 Transformation of waste components

Many components of the MSW stream contain potentially hazardous constituents. For example silver, chromium, lead, tin and zinc are used in surface coatings, galvanizing, solder and other surface applications. Metals are also used in pigments, inks, stabilizers for plastics, clay fillers, whiteners and photosensitizers. A typical MSW contains 7.6% by weight of ferrous metal, 1.1% aluminum, 0.06% copper-base metal and 0.14% zinc-base metal (Law & Gordon 1979). A USEPA study estimated that 213,000 tonnes of lead were present in the 1986 MSW stream, 80% in lead-acid batteries and the remainder in consumer electronics, glass, ceramics, plastics, soldered cans and pigments: Approximately 1800 tonnes of cadmium were disposed of in 1986 in rechargeable nickel–cadmium batteries, plastics, consumer electronics, appliances, pigments, glass and ceramics (Franklin Associates Ltd 1989).

Trichloroethene, a halogenated solvent, is found in drain and pipe cleaners, shoe polish, spot removal, paint removers, upholstery cleaners, septic tank cleaners (a significant source of groundwater contamination) and adhesives (Schaumburg 1990). Polyaromatic hydrocarbons are found in the carbon black used in newspaper ink. Phthalate esters are used as plasticizers in plastic manufacturing.

The majority of these hazardous materials are relatively unavailable for environmental release. It is estimated that only approximately 3–5% of the MSW mass is readily leachable (Cameron 1978). However, through physical, chemical and biological mechanisms such as dissolution, reduction, oxidation, hydrolysis and biotransformation, waste components can be transformed into significantly more mobile (and potentially toxic) forms.

Corrosion of elemental metals can lead to the release of metal ions to the leachate. Ferrous metal corrosion under anaerobic, acidic conditions involves the consumption of hydrogen ions and the release of ferrous ions as shown in the following reactions:

$$2H^+ + 2e^- \rightarrow H_2$$
$$Fe + 2H_2O \rightarrow Fe^{+2} + 2OH^- + 2H^+ + 2e^-$$

Many organic compounds detected in landfill leachates and gases are produced during the biotransformation of less mobile organic compounds. Several phenolic compounds are biodegradation products of lignin, a major component of plant tissue. Many

halogenated aliphatic compounds are transformed under anaerobic conditions. Vinyl chloride, an extremely mobile and toxic compound, can be an intermediate or end product of the transformation of several commonly used solvents including tetrachloroethene, trichloroethene and trichloroethane (McCarty 1991).

Plant tissue is also a significant source of the major inorganic ions found in leachates. Major components of plant tissue found after ashing include silicon, aluminum, iron, calcium, potassium, sodium, magnesium, nitrogen, phosphorus, sulfur and chlorine (Bohn *et al.* 1985). Many of these ions are released following lysing of plant cells. While these components are generally not considered hazardous, they do contribute to the ionic strength of leachate and may play a role in the solubility of both inorganic and organic toxic pollutants.

4. Fate of toxic pollutants in MSW landfills

From the above discussion, it is apparent that hazardous materials are frequently codisposed with MSW. Presumably, the fate of these compounds is determined by the operative processes inherent to the natural stabilization phases occurring within the landfill. Contaminants tend to partition among aqueous, solid and gaseous phases of the landfill Contaminant mobility and fate are largely determined by the magnitude of the preference for one phase relative to another which is a function of the physical chemical characteristics of both the contaminant and the phases present.

Figure 1 depicts the transport transformation phenomena which may affect the environmental fate of a landfilled contaminant. Mechanisms of mobility and transformation include biotransformation, volatilization, dissolution and advection, sorption and chemical reactions such as precipitation, reduction, oxidation and hydrolysis. Biotransformation and chemical reaction can reduce contaminant mass, however, a more toxic and or mobile compound may be produced. Dissolution and advection results in the movement of the compound with the bulk flow through the refuse pore spaces Similarly, volatilization and transport by the product gas can remove the more volatile contaminants from the landfill. Sorption and precipitation can retard contaminant movement as the compound interacts with the solid phase. Transport can be influenced by compound complexation or chelation which can either retard movement if the complex becomes associated with the solid phase or enhance mobility if the compound "piggybacks" on a more soluble complexing agent. A more complete description of operative fate mechanisms in the landfill environment is provided elsewhere (Reinhart 1991).

5. Solid waste management trends

The U.S. Congressional Office of Technology Assessment recently recommended a comprehensive national policy toward the reduction of MSW toxicity and quantity (Levenson 1990). Toward that end, numerous solid waste management policies and activities have been proposed or are presently in effect which will reduce emissions of hazardous substances from landfills. Several examples are identified below.

- *Collection of household hazardous wastes.* Since 1981 hundreds of household hazardous waste (HHW) collection programs have been conducted in over 30 states. Permanent HHW disposal facilities are being provided at many landfill sites. Public awareness of HHW disposal concerns is increasing throughout the country as a result of the collection programs.

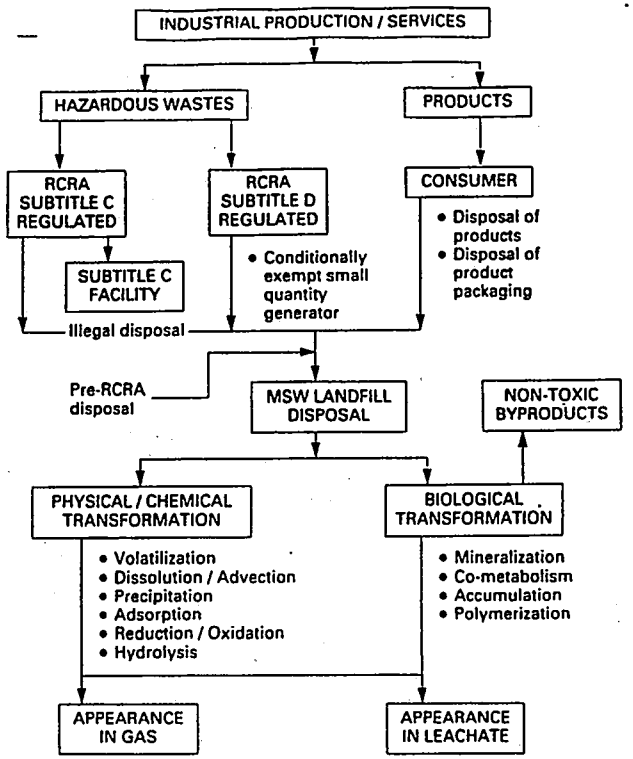

Fig. 1. Origin, pathways and fate of hazardous pollutants in U.S. MSW

- *Collection load inspection.* Federal and state MSW landfill regulations and require routine random inspection of incoming loads for regulated hazardous wastes.
- *Enforcement actions.* Increased enforcement of hazardous waste management regulations on the local, state, and federal level is minimizing illegal disposal of regulated hazardous wastes in MSW landfills.
- *Regulating small quantity generators.* Several states are regulating all generators of hazardous wastes, requiring disposal of these wastes in permitted hazardous waste disposal facilities.
- *Product reformation.* Many changes by manufacturers in product composition have reduced toxicity. Examples include the reduction of mercury in alkaline batteries

(expected to reach near zero by 1993 (Amos 1991)), elimination of lead from paints, reduction of lead use in can soldering, elimination of tetrachloroethene in fabric sprays and trichloroethene in typographical correction fluid and the elimination of mercury as a fungicide in paint.

- *Hazardous waste minimization.* The USEPA has adopted a policy of promoting hazardous waste minimization over end-of-pipe treatment through better housekeeping practices, product reformation, recycling and changes in raw materials and processing equipment.
- *Landfill design.* Design of MSW landfills to optimize waste biodegradation, leachate collection and treatment, gas collection and treatment will minimize release of toxic pollutants. Entombment of MSW will only delay the release of these materials.
- *Related Federal regulations.* Passage of the U.S. 1990 Clean Air Act Amendments requires reduction in toxic releases from industry which may necessitate reformulation of products and process modifications. The U.S. Federal Insecticide, Fungicide and Rodenticide Act has banned or regulated use of many pesticides.

6. Summary and conclusions

The presence of hazardous materials in MSW has been confirmed by the potential toxicity of liquid and gaseous releases from MSW landfills, as well as the known contamination of groundwater, air and surface water near these landfills. The sources of these wastes include household hazardous wastes, small quantity generators, illegal disposal practices and transformation of wastes during waste stabilization. Once placed in a MSW landfill, hazardous substances are subject to the same physical, chemical and biological processes as all waste types, which may lead to their volatilization, dissolution and advection, precipitation, sorption, reduction, oxidation and or biotransformation.

Recent trends in product manufacturing and solid waste management foretell a likely reduction in the concentrations of hazardous components from landfill emissions with obvious benefits to environmental quality. These new measures include collection of household hazardous wastes, load inspections, improved enforcement of hazardous waste regulations, product reformulation and improved landfill design and operation. With the regulation of small quantity generators generating more than 100 kg of hazardous wastes per month in 1986, over 72% of SQG wastes once permitted in MSW landfills are now prohibited from MSW landfill disposal.

Wastes placed in landfills in the past, present and future will, in some manner, influence the environment for many decades. Control measures which reduce the adverse impact of hazardous wastes present in MSW landfills may include landfill gas capture and treatment, impermeable landfill caps and liners, leachate collection, recirculation and treatment (depending on climatic conditions) waste composition and facility size and design characteristics. Minimizing future adverse environmental impacts from MSW landfilling requires both public and private diligence to reduce the toxicity of solid waste and to ensure proper collection, handling and disposal of the waste once it is generated.

Introduction

> For fundamental and deeply rooted psychological reasons, as well as more mundane utilitarian considerations, it is characteristic of man to bury that which he fears and wishes to rid himself of. In the past, this engrained pattern of behavior has generally proven harmless and, indeed, has often led man to restore to the earth the substances he had removed from it. In today's industrialized society, however, the routine practice of burying highly toxic chemical wastes has resulted in serious threats to the environment and to public health. . . . The dangers are especially acute when buried chemical wastes threaten to contaminate the underground aquifers, upon which half of the nation relies for its supply of drinking water.[1]

In the eight years since its utterance, Judge Stanley S. Brotman's forecast has been the prologue to a national environmental crisis triggered by the prevalence of toxic contamination. No one is in control of the nation's hazardous waste. As many as 50,000 sites may require hundreds of billions—perhaps even trillions—of dollars

1. United States v. Price, 523 F. Supp. 1055, 1057 (D.N.J. 1981), *aff'd*, 688 F.2d 204 (3d Cir. 1982).

to render them environmentally safe and to protect drinking water supplies.[2] Only the tip of the toxic iceberg is now visible.

The United States Environmental Protection Agency (EPA) may be misallocating this monumental cleanup burden in contravention of the law by excusing too many of those entities liable under the Superfund statute and thereby increasing the burden on other potentially liable parties. The question of who underwrites the most expensive and sweeping waste cleanup in the nation's history is at issue, and the intricacies of this legal controversy will dominate the toxic debate into the future.

At issue is municipal and regional governmental liability for the handling and disposal of municipal solid waste—backyard garbage. The EPA shifts an immense share of the cost of toxic waste cleanup from the public to the private sector by excusing from prosecution governmental entities that dump hazardous garbage at privately operated sites. This Article analyzes this widespread practice and argues that under the current statute it violates federal hazardous substances laws.

Section I dissects the municipal waste stream, assessing the volume, toxicological, and hazardous constituents of those substances America discards as waste. This section traces waste from the garbage pail to its entry into the nation's drinking water supply. During the process, many of the elements of common household products are transformed into toxic ghosts that will haunt the American future.

Section II evaluates federal regulation of hazardous waste and reveals how today's waste control solutions are destined to become tomorrow's environmental crises. Section III examines the practical implications at the Charles George Superfund site, illustrating in graphic and real terms the conflict posed by the EPA enforcement position regarding municipal solid waste.

Section IV describes the regulatory framework of the federal Superfund, illustrating the hue and texture of the Comprehensive Environmental Response, Compensation and Liability Act's (CERCLA's or the Superfund's) statutory canvas. Section V analyzes the developing federal common law strictly defining liability associated with the disposal of hazardous substances, with particular emphasis on municipalities and municipal solid waste. Section VI examines the Superfund and the abrogation of Eleventh Amendment sovereign immunity, concluding that although recent precedent partly penetrates the shield of sovereign immunity, new legislative amendments leave doubt as to whether sovereign immu-

2. Ferrey, *A Liability Cost Cities Can't Throw Away*, L.A. Times, Oct. 20, 1986, pt. II, at 5.

nity remains intact. In addition, this section explores theories under which municipalities may be able to avail themselves of the sovereign shield, thereby avoiding hazardous waste liability.

Section VII analyzes the exercise of EPA prosecutorial discretion in federal hazardous waste enforcement. A "Catch-22" grips hazardous waste law and disadvantages a class of parties who are left with no interlocutory judicial review.

Section VIII unravels the intertwined double helix of the Resource Conservation and Recovery Act (RCRA) and the Superfund. The legal chemistry of this relationship allows the government to allocate billions of dollars of waste cleanup responsibility to both private and municipal parties. The legality of this allocation is an explosive toxic liability issue confronting both the American legal community and American policymakers.

Finally, Section IX sets out criteria for the administration of an environmental decision rule that would allow a flexible and fair approach to municipal liability. Currently, the EPA often exempts municipalities from prosecution concerning private hazardous waste sites on policy grounds. Although municipalities are legally and practically distinct from private entities, creative and equitable allocation schemes are preferable to an administrative grant of prosecutorial immunity that finds no support in the underlying statute.

I. *Beyond the Pail: The Hazardous Constituents of Municipal Solid Waste*

The industrial nations are neck-deep in waste. All waste, whether liquid, gaseous, or solid, is characterized as "solid" waste. Some solid wastes are "sanitary," although others are hazardous. Municipal garbage collected from households is designated as municipal solid waste (MSW) and is appropriately disposed of in sanitary landfills.

About one third of the total wastes collected in some communities are "household wastes."[3] Detailed surveys indicate that only about three percent of MSW is recycled; the remainder is thrown out.[4] In 1976, the United States officially produced and placed in landfills more than 360 million tons of solid waste created by municipal, commercial, and industrial sources.[5] On a per capita basis, each

3. *See* CAL. RECOVERY SYS., INC., NORTH SANTA CLARA COUNTY COMPREHENSIVE WASTE CHARACTERIZATION STUDY (1982-83): FINAL SUMMARY REPORT, REP. NO. 83-10, at 12 (discussing constituents of household waste). This study analyzes seasonal samples of a variety of waste streams in California. *See id.*

4. Glaub, Savage & Henderson, *Comprehensive Waste Characterization on a Quarterly Basis*, in 1984 NATIONAL WASTE PROCESSING CONFERENCE, AMERICAN SOCIETY OF MECHANICAL ENGINEERS 198 (copy on file at the *George Washington Law Review*)

5. Griffin, Shimp, Steele, Ruch, White & Hughes, *Attenuation of Pollutants in Municipal Landfill Leachate by Passage Through Clay*, 10 ENVTL. SCI. & TECH. 1262 (1976) [hereinafter *Attenuation of Pollutants*]. This disposal had an annual cost of more than $1.5 billion. Additionally, each day Americans flush an estimated 6.8 billion gallons of sewage. Licht & Johnson, *Without a Paddle*, 17 ENVTL. ACTION 10, 13 (1985).

American is responsible for the creation of approximately 2.5 to 4 pounds of MSW each day.[6] This amount varies depending on the degree of urbanization,[7] the season,[8] the average income level,[9] and level of economic activity.[10] In 1984, 133 million tons of this waste were MSW.[11]

Estimates of the amount of this and other waste that is hazardous vary. Annually, in the United States more than 4 billion tons of hazardous materials, including gasoline and radioactive materials, are transported by land, sea, and air.[12] In turn, the EPA estimates that these hazardous materials generate about 40 million tons of hazardous wastes annually in the United States,[13] although the United States Office of Technology Assessment (OTA), a congressional agency, places the amount at approximately 255 to 275 million tons

6. BUREAU OF SOLID WASTE DISPOSAL, DEP'T OF ENVTL. QUALITY ENG'G, COMMONWEALTH OF MASS., WASTE COMPOSITION STUDIES 6 (1986) (copy on file at the *George Washington Law Review*). This definition of MSW includes residential and commercial waste, including discarded appliances and tires. Reported MSW generation ranges from about 2.3 to 6.58 lbs./capita/day, (2,400 lbs./capita/year). When residential waste can be separately identified, it ranges from about 1.4 to 2.8 lbs./capita/day. *Id.*

7. *Id.* at 7-8. To account for the effect of community size on waste generation, a desktop study of materials recovery in Vermont and New Hampshire assumed that generation was 2.4 lbs./capita/day in communities of fewer than 4,500 persons, and 2.8 lbs./capita/day in communities larger than 4,500 persons. *Id.* A Dane County, Wisconsin Solid Waste Plan also found that generation rates were lower in rural areas than in urban areas. To calculate overall county generation rates, the Dane County planners assumed the following generation rates: 2.2 lbs./capita/day in urban areas of 10,000 or more; 1.6 lbs./capita/day in towns of 2,500 to 10,000; 1.0 lb./capita/day in rural areas with incorporated places; .85 lbs./capita/day in very rural areas with one or fewer incorporated places of 1,000 or less. *Id.*

In another study, Delaware landfill records showed annual waste generation of 2.4 lbs./capita/day (880 lbs./capita/year) in rural areas, and 6.6 lbs./capita/day (2,400 lbs./capita/year) in wealthy coastal areas. *Id.* at 8.

8. *Id.* A study of waste generation in Portland, Maine found that total waste generation could vary from 80 to 120% of the average monthly rate depending on the season. The study reasoned that the seasonal recreational population may cause extensive seasonal variation. *Id.*

9. *Id.* Although noting that income levels cannot provide a simplistic explanation for waste generation, the Milwaukee Garbage Project reported that lower income households appear to generate more household waste than middle- or upper-income households. This was attributed to different consumption patterns that resulted in the use of more packaging. *Id.*

10. *Id.* The Dane County Plan noted a correlation between the rate of increase of the GNP and per capita solid waste generation rates. *Wastepaper: The Future of a Resource*, a 1982 report, also found an increase in per capita waste generation with time. Nationwide, the authors of this report estimated combined residential and commercial waste generation at 3.29 lbs./capita/day in 1971, and 3.47 lbs./capita/day in 1980. This report projected continuing increases, estimating that waste generation will rise to 3.66 lbs./capita/day by 1990. *Id.*

11. *EPA Study Finds Older, Unlined Landfills More Likely to Adversely Affect Environment*, 17 Env't Rep. (BNA) 1221, 1222 (Nov. 21, 1986).

12. U.S. OFFICE OF TECHNOLOGY ASSESSMENT, TRANSPORTATION OF HAZARDOUS MATERIALS: STATE AND LOCAL ACTIVITIES 3 (1986). This figure, however, does not represent all hazardous "wastes." *See id.*

13. S. EPSTEIN, L. BROWN & C. POPE, HAZARDOUS WASTE IN AMERICA 7 (1982).

per year.[14] This range represents an aggregate of 350 to 2,000 pounds of hazardous waste per person each year. That is, the OTA believes that six times more hazardous waste is being produced than the EPA thinks it is regulating.[15]

The EPA historically presumes that municipal solid waste is sanitary, non-hazardous rubbish.[16] Most people also believe that MSW constitutes old newspapers, leftover food, random household debris, and the occasional broken toy. The EPA historically assumes that the home trash barrel represents the outflow of only the supermarket or greengrocer, and that on the whole the resultant waste should be no worse than the sum of its parts.

Although the composition of residential waste varies seasonally,[17] as much as 50% is various paper products, 5-10% is plastics, 20-30% is yard waste, and 3-8% is food, while remaining shares are ferrous metals (3-6%), aluminum (0.6-1.3%), glass (4-11%), and miscellaneous inorganic matter (0.1-3%), as illustrated in Table 1.[18] About 74% of the gross volume of MSW would be suitable for combustion if, in lieu of landfilling, it became part of a waste-to-energy conversion process.[19] Table 2 illustrates the elemental share of organic materials in MSW.

Recent scientific data expose the fallacy of assuming that MSW is sanitary waste. The home garbage pail is a leaking sieve of toxic and potentially toxic chemical agents. Some of these chemicals are contained in the pesticides, paints, degreasers, preservatives, detergents, oven cleaners, insecticides, and even shampoos sold ubiquitously over the counter to consumers.[20] Other elements in household waste can become hazardous during the decay and decomposition process. Either alone or in chemical consort with other wastes in a landfill, the chemical outflow from the typical household is a ticking toxic time bomb.

Research conducted in Nassau County, New York estimates that

14. Mosher, *EPA Still Doesn't Know the Dimensions of Nation's Hazardous Waste Problem*, Nat'l J., Apr. 16, 1983, at 796.

15. *Id.* EPA officials in 1983 claimed to regulate only 40-45 million tons of hazardous waste. *Id.* at 797. Inadequate recordkeeping makes it impossible for the EPA to tell whether waste generation is increasing or decreasing. *See Data on Waste Generation, Management Said Inadequate for Key Policy Decisions*, 17 Env't Rep. (BNA) 1784, 1784 (Feb. 20, 1987).

16. *See infra* text accompanying notes 102-40.

17. In warmer months yard waste increases, food waste decreases, and other wastes show various fluctuations in volumes. CAL. RECOVERY SYS., INC., *supra* note 3, at 21; Glaub, Savage & Henderson, *supra* note 4, at 204.

18. *Cf.* Glaub, Savage & Henderson, *supra* note 4, at 199-202 (finding similar composition of residential waste). The organic share is approximately 42% carbon and 40% oxygen. *Id.* at 210.

19. *Id.* at 198. Residential solid waste has a heating value of about 4,200 BTU per pound. *Id.* at 208. Given the "tipping fee" that municipalities will pay to a refuse-driven fuel facility to take MSW, it becomes very competitive to treat MSW as a prime fuel source compared to conventional fossil fuels.

20. *See generally* EPA, REP. NO EPA-600/2-80-128, SOURCES OF TOXIC COMPOUNDS IN HOUSEHOLD WASTEWATER (August 1980) (suggesting that the identification and concentration of toxic pollutants resulting from consumer products and discharged in domestic wastewater must be studied further).

in that county alone, hardware, supermarket, department, and automotive stores annually sell 288,000 gallons of consumer products containing organic carcinogens, suspected carcinogens, or other harmful organic materials.[21] Consumers dump some of these

21. J. Dowling, Report on Survey of Consumer Products Containing or Suspected of Containing Harmful Organic Chemicals and Having the Potential of Contaminating the Groundwater of Nassau County, New York 4 (May 1979) (copy on file at the *George Washington Law Review*).

chemical compounds directly onto the ground, others are discharged into cesspools and escape into the ground, and still others are disposed of in household trash and are collected for disposal at municipal solid waste landfills.

Telephone surveys reveal that the most commonly used and discarded hazardous household substances, in descending order, are household cleaners, pesticides, auto and furniture polishes, paint and paint thinners, motor oil, chemical drain openers, antifreeze, wood preservatives, and herbicides.[22] Paint products, solvents, batteries, pesticides and herbicides, adhesives, aerosols, alcohols, oils and grease, polishes and waxes, cosmetics, and dyes contain dozens of metals as well as halogenated and nonhalogenated compounds,[23] all of which qualify as hazardous substances under federal law.[24] A number of elemental metals in significant concentrations are found in MSW,[25] and both soluble fluorides and chlorides are found at average concentrations of 1,900 parts per million (ppm).[26]

The organic fraction of MSW contains both pesticides and herbicides.[27] Some pesticides found in MSW are up to thirty years old

Source: Cal. Recovery Systems Inc., North Santa Clara County Comprehensive Waste Characterization Study (1982-83), January 1984, at T3:46.

An examination of the waste stream in King County, Washington identified approximately 1,500 distinct potentially hazardous items in waste loads from ninety-one vehicles.[29] Very little effort is made to collect and contain household hazardous waste separately, and even when the effort is made, fewer than one percent of households

toxaphene. Phosphate pesticides detected in significant concentrations include diazinon, ethyl parathion, malathion, and methyl parathion (this last in the parts per million range). Chlorinated phenoxyacid herbicides detected include: 2,4-D; 2,4,5-T; and 2,4,5-TP. *Id.*

28. King County, *supra* note 22, at 22.

29. *Id.* at 3.

typically participate.[30] Such low participation rates will not begin to remove hazardous waste from the MSW stream.

Volatile organic solvents (VOCs) are a group of organic compounds of low molecular weight, and are common in many household products. The EPA lists many of these chemical compounds as priority pollutants, subject to direct regulation as toxic chemicals.[31] VOCs evaporate quickly when exposed to air at normal temperatures; however, when saturated in soil or blended with groundwater streams, VOCs remain present for extended periods of time.[32] VOCs in the ground pose a special threat when they become mobile in the soil and reach the groundwater.[33]

If dumped in a municipal solid waste landfill, these chemicals can seep or "leach"[34] into the ground and into the groundwater. After a thorough examination of hazardous constituents in household waste, one research team concluded that "[t]he volatile organic chemical species likely to contaminate groundwater enter the waste stream primarily in the form of paint and paint products, solvents, and cosmetics. The lead enters the waste stream primarily in the form of paint and paint products and in the form of batteries."[35]

The stability of VOCs in the ground is influenced by temperature,

30. Special Wastes Branch, Office of Solid Waste, EPA, Rep. No. EPA/530-SW-86-038, A Survey of Household Hazardous Wastes and Related Collection Programs 1-3 (1986) [hereinafter Household Hazardous Waste Survey] (noting that "[f]ew programs can boast participation of even 1 percent . . . and several programs report participation less than 0.2 percent"). Only one percent of Massachusetts households in a target community participate in hazardous waste material collection days. Executive Office of Envtl. Affairs, Massachusetts State House Press Files (Aug. 12, 1985).

31. *See* 40 C.F.R. § 302.4 (1988); *see also* P. Wood, R. Lang & I. Payan, Anaerobic Transformation, Transport and Removal of Volatile Chlorinated Organics in Groundwater (Sept. 1981) (unpublished research paper) (stating that many VOCs included on the EPA's priority pollutant list are found in contaminated groundwater sites) (copy on file at the *George Washington Law Review*). Typical low-solubility volatile organics found in contaminated wells include aliphatics (including propane, straight, or branched chain hydrocarbons), aromatics (benzene, toluene, ethylbenzene, etc.), chlorinated aromatics (mono- and dichlorobenzenes, etc.), halogenated alkanes (chloroethane, mythelene chloride, 1,1- and 1,1,1- chloroethanes, trihalomethanes), and chlorinated ethenes (vinyl chloride, vinylidene chloride, cis- and trans-1,2-dichloroethylene, trichloroethylene, tetrachloroethylene). *Id.*

32. *See* Sabel & Clark, *Volatile Organic Compounds as Indicators of Municipal Solid Waste Leachate Contamination*, 1984 Waste Mgmt. & Res. 119, 119 (copy on file at the *George Washington Law Review*).

33. VOCs are mobile under most soil and pH conditions, although they vary as to their solubility in water. Even the most immiscible VOCs are rendered more soluble in water if dissolved organic compounds are present. *Id.*; *see also* Council on Envtl. Quality, Contamination of Ground Water by Toxic Organic Chemicals (1981) (discussing the contamination of groundwater by the movement of waste from industrial and municipal landfills).

34. "Leachate" is liquid or water soluble contaminated substances that migrate away from the point source of contamination in groundwater or surface water, often influenced by rain and normal water table activities. Such a phenomenon is described as a "leaching" of contaminants.

35. King County, *supra* note 22, at 28.

light, soil composition, moisture, sedimentation, and the presence or absence of oxygen.[36] VOCs are not readily biodegraded or absorbed into the soil, and they can move rapidly through soil to groundwater.[37] In low concentrations these compounds can be degraded anaerobically, but not aerobically.[38]

VOCs are now present in a large number of groundwater drinking supplies nationwide. The ingestion of VOCs, even in small quantities, causes significant public health risks because many of the halogenated organic chemicals found in groundwater are suspected or confirmed carcinogens or mutagens.[39]

Contamination of groundwater at and surrounding sanitary MSW landfills has been documented in recent studies. Research of groundwater samples from twenty MSW landfills in Minnesota found that nineteen or more distinct organic pollutants were present at twelve of the landfills.[40] Of particular importance, the Minnesota data indicate that there is no chemical distinction between the type and amount of organic pollutants present at the rural—in regions where there is no manufacturing waste—and urban landfills surveyed.[41] The rural landfills, which contain only *household* waste, therefore pose contamination problems identical to the urban landfills, which contain both household and industrial (supposedly hazardous) waste. An OTA study surveying MSW facilities leaching hazardous substances revealed that "[g]enerally the contaminants found at the [sanitary] facilities and their frequency resemble what has been found at all [Superfund] sites. . . . All the information suggests that solid waste sites on the NPL [National Priority List] score similarly to NPL sites that dealt solely with hazardous wastes."[42]

Several other examples present similar findings. In Norman,

37. Sabel & Clark, *supra* note 32, at 121 (relying on an unpublished 1983 research report on groundwater contamination for the Minnesota Pollution Control Agency); Bouwer, Rittman & McCarty, *Anaerobic Degradation of Halogenated 1- and 2-Carbon Organic Compounds*, 15 Envtl. Sci. & Tech., 596, 596 (1981); *see also* Parsons & Lage, *Chlorinated Organics in Simulated Groundwater Environments*, Res. & Tech., May 1985, at 52, 57-59 (concluding that some VOCs (e.g., chlorinated alkenes) are particularly resistant to biotransformation and are therefore troublesome pollutants because they persist in the groundwater).

38. Bouwer, Rittmann & McCarty, *supra* note 37, at 599. For a discussion of the prevalence of anaerobic transformation of parent-daughter volatile organic compounds, see P. Wood, R. Lang & I. Payan, *supra* note 31, at 2-4.

39. *See* Bouwer, Rittmann & McCarty, *supra* note 37, at 596. Population groups exhibit a higher incidence of various forms of cancer from exposure to low levels of VOCs. For example, the incidence of gastrointestinal cancers increases when population groups are exposed to chlorinated water containing VOCs. Sabel & Clark, *supra* note 32, at 120.

40. Sabel & Clark, *supra* note 32, at 120-21 & Table 1.

41. *Id.* at 123.

42. Office of Technology Assessment, Superfund Strategy 131 (1985) [hereinafter Superfund Strategy]. By late 1984, the EPA had listed 538 sites on the NPL. Office of Solid Waste & Emergency Response, EPA, Extent of the Hazardous Release Problem and Future Funding Needs: CERCLA Section 301(a)(1)(C) Study 1-5 (1984). The EPA classified 163 of these sites as containing municipal refuse or as municipally owned landfills. *Id.* at 5-6. The remaining NPL sites include: commercial/industrial landfills, RCRA Subtitle C hazardous waste facilities, mining waste sites, leaking underground storage tanks, and radioactive waste sites. *See id.* at 5-2 to 5-11.

Oklahoma, the groundwater surrounding a municipal landfill, which never received appreciable amounts of industrial waste, contains hazardous substances.[43] Leachate from municipal waste landfills in the Central Valley of California contains volatile organic contaminants.[44] Sixty-seven percent of representative landfills in New Hampshire show evidence of groundwater contamination.[45] Groundwater studies in Wisconsin and New York further corroborate the presence of widespread organic contamination of groundwater.[46]

As of 1978, a comprehensive program on Long Island, New York, designed to monitor all 440 public water wells in Nassau County, established that more than sixteen percent of the wells tested were contaminated by at least one or more of the six organic chemicals monitored.[47] Although some organic compounds are not soluble in water, they are soluble in other organic compounds which are themselves water soluble.[48] Certain compounds may become carriers of other organic pollutants, allowing the pollutants to intermix with groundwater supplies.

If soil exhibits a low pH (high acidity), there may be less microbial activity, slowing the biological transformation of VOCs into daughter compounds.[49] The presence of exotic forms of chlorinated organic compounds in groundwater raises significant concern regarding the long-term impact of VOCs which penetrate the ground.[50] For example, in areas of Florida where industries use degreasing compounds that are not discovered in the well water, their progeny (in the form of daughter compounds) are nonetheless

45. *Id.* at 11 (Figure 4: Summary of Compliance Shortfalls: Representative New Hampshire Landfills and Districts (reproduced from The Landfill Threat to New Hampshire's Drinking Water: Findings and Proposals for Action (1986))). Moreover, 95% of New Hampshire landfills operate in violation of applicable law. *Id.*

46. *See* Sabel & Clark, *supra* note 32, at 125-26 (citing data from MSW leachate studies conducted in New York and Wisconsin).

47. Geraghty & Miller, Inc., Supplemental Report to the Nassau-Suffolk Regional Planning Board on the Current Status of Ground-Water Investigations for Organic Chemicals in the Nassau-Suffolk Area at 3, 6 & Table 2 (Feb. 1979) (unpublished study) (copy on file at the *George Washington Law Review*). The Nassau County monitoring wells tested positive for the following organic chemicals, in decreasing order of prevalence: 1,1,1-trichloroethane, trichloroethylene, tetrachloroethylene, chloroform, carbon tetrachloride, 1,1,2-trichloroethane, and trifluorotrichloroethane. *Id.* at 7 (Table 3).

48. Sabel & Clark, *supra* note 32, at 121; *see also supra* note 33. For example, the compounds trichloroethylene and tetrachloroethylene are not particularly soluble in water. However, more soluble compounds such as alcohol or benzene increase the solubility of the former, thereby increasing the synergistic contamination of groundwater sources when these chemicals are present in combination. *Id.*

49. *See* Parsons & Lage, *supra* note 37, at 59.

50. *Id.* at 52.

prevalent in well water.[51] This data strongly suggests that chlorinated organic solvents may be anaerobically transformed in the groundwater to exotic daughter compounds.[52] Chlorinated organic compounds can transform themselves in both sterile environments and environments where bacteria are present,[53] and recent research now suggests that VOCs can be transformed by both chemical and biological processes.[54] Viewed in its entirety, this evidence strongly supports the argument that the constituents in ordinary household wastes alone are toxic and are capable of contaminating groundwater.

Although there are fewer toxic constituents per unit of volume of MSW than industrial waste, the enormous tonnage of MSW landfilled annually yields large quantities of potentially toxic elements. There is no definitive survey measuring the percentage of household waste that is hazardous, yet a waste analysis by one of the most experienced American waste consulting teams indicates that "[h]azardous wastes make up less than 0.1% by weight of the municipal waste stream."[55] In a more detailed 1984 study, the Los Angeles County Sanitation Districts estimated that 0.00147% of all refuse discarded at five of its municipal facilities qualified as hazardous.[56] These estimates, however, may be low.[57]

Today's household waste, routinely discarded, is dissolved, cloned, and transformed in the nation's dumps. Its toxic progeny return through the tap as contaminated drinking water. The biological circle is complete. The long-term impact of MSW spills beyond the pail.

51. *Id.* That is, studies show the presence of vinyl chloride, cis- and trans-1,2-dichloroethene, and vinylidene chloride in municipal wells in areas where these substances are not used, indicating that these exotic compounds could result from transformation of chlorinated organic solvents. *Id.*

The authors observed that under methanogenic conditions, 1,2-dichloroethane, carbon tetrachloride, and chloroform were oxidized to carbon dioxide. In addition, reductive dechlorination transformed tretrachloroethene and 1,1,2,2-tetrachloroethane. *Id.* at 1286, 1293.

54. *Id.* at 1293; Parsons & Lage, *supra* note 37, at 53, 56.

55. SUMMARY OF STUDIES, *supra* note 22, at 12 (construing a 1985 project feasibility report prepared for the Northern Santa Clara County Solid Waste Management Authority based on the study by Glaub, Savage & Henderson, *supra* note 4).

56. HOUSEHOLD HAZARDOUS WASTE SURVEY, *supra* note 30, at 4-7. The Los Angeles municipal waste stream that was analyzed included some commercial as well as residential waste. *Id.* In Albuquerque the presence of hazardous waste in the residential waste stream is estimated to be 0.5 %. *Id.* at 4-11.

57. The Los Angeles project was concerned with identifying commercial size quantities, and therefore looked only for containers greater than one gallon or whole boxes containing hazardous waste. *See id.* at 4-7. This tends to undercount the actual volume of hazardous constituents.

II. Landfill Overspill: The Failure of Federal Regulation

The great bulk of hazardous waste in the United States is dumped in landfills.[58] About two thirds of this hazardous material, however, is improperly disposed of, and therefore continues to pose a potential health threat.[59] A significant part of this dumping occurs in an unregulated and unreported manner, as most regulated facilities fail to comply with the hazardous waste disposal laws.

In a study conducted for the Office of Management and Budget, the EPA found that more than sixty percent of the nation's known hazardous waste facilities fail to comply with federal groundwater monitoring requirements,[60] and more than twenty percent of inspected landfills are cited for contaminating either the air or the water.[61] Experts also posit that the liners placed in landfill sites to protect against leakage are more permeable than anticipated, resulting in potential leachate migration problems.[62]

The OTA projects that cleaning up just 10,000 of the 50,000 possibly contaminated hazardous waste (or Superfund) sites will cost several hundred billion dollars over fifty years.[63] This estimate of 10,000 possible cleanup sites does not include as many as 100,000 currently leaking underground storage tanks, and these may number as many as 350,000 within five years.[64] This multi-billion dollar price tag will be divided principally among those who own or operate the disposal sites and those who generated the hazardous substances which lie buried beneath them.[65]

62. Anderson, *Does Landfill Leachate Make Clay Liners More Permeable?*, CIVIL ENGINEERING-ASCE, Sept. 1982, at 66, 66-69. Anderson explains that the permeability of clay liners is usually tested only with relatively pure water. Actual leachates generated in landfills, however, may be highly contaminated or contain organic liquids, greatly increasing the permeability of the clay liners. *Id.*

63. SUPERFUND STRATEGY, *supra* note 42, at 3, 61. Cost estimates vary from a low range of $5.6-$33.8 billion to clean up 1,270-2,546 sites, as estimated by the General Accounting Office, to a high value of $29-92 billion to remediate 2,200-7,000 sites, projected by the National Audubon Society. The latter estimates that this cleanup could take as long as 84 years. *Id.* at 14, 62.

64. D. Feliciano, Leaking Underground Storage Tanks: A Potential Environmental Problem (Jan. 11, 1984) (unpublished report, released only to members of Congress by the Congressional Research Service, Washington, D.C.).

65. According to the OTA, more than 99% of all federal and state environmental spending is devoted to controlling pollution after the waste is generated, rather than on

In assessing the responsibility of owners and operators, the federal government has only recently acknowledged the hazardous potential of MSW landfills. In 1984, the EPA identified municipal landfills as an emerging problem area that will require intensive discovery and investigation.[66] Municipal landfills may have received hazardous wastes prior to 1980; further, unregulated small-quantity hazardous-waste generators continue to dispose of their wastes in municipal landfills, and landfills also continue to receive household solvents, cleaning materials, and pesticides.[67] Similarly, in reauthorizing the Resource Conservation and Recovery Act (RCRA)[68] in 1984, Congress took notice of the real and imminent danger of hazardous contamination at MSW sanitary landfills:

> Subtitle D facilities are the recipients of unknown quantities of hazardous waste and other dangerous materials resulting from the disposal or [sic] household waste, small quantity generator wastes and illegal dumping. Since construction, siting, and monitoring standards for these facilities are either nonexistent or less restrictive than those governing hazardous waste disposal facilities, environmental and health problems caused by Subtitle D facilities are becoming increasingly serious and widespread. A high proportion of sites listed on the National Priority List were sanitary landfills. Without the additional environmental protection that the implementation of this provision will provide, even more Subtitle D facilities are destined to become Superfund sites.[69]

About twenty percent of the National Priority List (NPL) Superfund sites are or were MSW disposal facilities.[70] This is particularly revealing given significant pressure to keep MSW sites off the NPL. This pressure originates at the state level, because designation of a government-owned and operated MSW disposal site on the NPL requires the state to pay at least fifty percent of the remediation costs and one hundred percent of the operation and

reducing the volume of hazardous waste. The latter alternative is more economical and less hazardous to human health and the environment. All hazardous wastes are amenable to waste reduction techniques and processes. SERIOUS REDUCTION, *supra* note 58, at 9, 11.

66. OFFICE OF SOLID WASTE & EMERGENCY RESPONSE, *supra* note 42, at ii, 5-1.

67. *Id.* at 5-6. Studies prepared by or for the EPA that corroborate the hazardous nature of MSW landfills include: MUNICIPAL ENVTL. RESEARCH LABORATORY, OFFICE OF RESEARCH & DEV., EPA, REP. NO. 70. SUPERFUND STRATEGY, *supra* note 42, at 11 (Table 1.1) (listing 550 Superfund sites as of 1985). The National Priorities List currently contains 797 listed sites and 378 sites proposed for listing, for a total of 1,175 sites. Telephone Inquiry to Superfund Hotline (Dec. 22, 1988) (telephone: (202) 382-3000).

management expenses incurred by the cleanup.[71] Although the state may recover this share from any municipality or county that owned or operated the facility, ultimately the assessment adversely impacts the local tax base. Similarly, the EPA—already confronting a number of states that have failed to raise the ten percent required matching funds for cleanup of privately owned sites—is reluctant to add more municipal sites to the NPL because this would raise the state's matching share to fifty percent.[72]

The OTA expects that half the future Superfund priority sites will be municipal landfills.[73] The EPA could also add sanitary waste sites that are not currently disposal sites for hazardous wastes to the growing number of Superfund sites.[74] More than fifty waste disposal facilities licensed under the RCRA interim status regulations[75] were among the first 500 sites placed on the NPL.[76] This track record does not engender confidence in the long-term security of licensed sanitary waste sites.

An EPA study reveals that only eleven percent of landfills have any type of bottom liner, only four percent employ a leachate collection and removal system, and only nineteen percent monitor the adjacent groundwater for contamination.[77] Between 1980 and 1985, the EPA closed one third of the nation's landfills because they threatened to contaminate nearby groundwater supplies, therefore failing to meet federal requirements.[78] And in 1985, the OTA concluded that "many, if not most, solid waste facilities have [posed]

71. *See* 42 U.S.C. § 9604(c)(3) (Supp. IV 1986). The state pays only 10% of remediation costs, plus all operation and maintenance expenses, if the facility was not directly or indirectly operated by the state at the time of the hazardous disposal. *Id.*; *see also infra* notes 168-70 and accompanying text (discussing the state's required contribution).

72. *See, e.g.*, SUPERFUND STRATEGY, *supra* note 42, at 27 (discussing the Seymour, Indiana site as an illustration of the problem of states being unable to meet their matching payment requirement).

73. *Id.* at 5.

74. Sanitary waste facilities are regulated under RCRA Subtitle D, 42 U.S.C. §§ 6941-6949 (1982 & Supp. IV 1986). These facilities are presumed to have accepted no hazardous wastes. RCRA Subtitle D regulates sanitary wastes at the disposal facility, rather than at the generation of sanitary waste. The mechanism for regulation is the promulgation of standards for disposal facilities and the requirement that state and regional authorities develop, subject to EPA approval, solid waste management plans. *Id.*

75. 40 C.F.R. § 265 (1987) (defining interim status standards for owners and operators of hazardous waste treatment, storage, and disposal facilities); *see also id.* § 270.70 (addressing qualifications for interim status). Interim status was a mechanism at the 1976 passage of RCRA to "grandfather" the temporary operation of existing facilities until EPA issued a permit. *See* 42 U.S.C. § 6925(e) (Supp. IV 1986).

76. SUPERFUND STRATEGY, *supra* note 42, at 138.

77. *EPA Study Finds Older, Unlined Landfills More Likely to Adversely Affect Environment*, 17 Env't Rep. (BNA) 1221, 1222 (Nov. 21, 1986).

78. *EPA Survey Finds RCRA Waste Facilities Have Declined Markedly in Number Since 1981*, 17 Env't Rep. (BNA) 1418, 1418 (Dec. 19, 1986). As of 1987, after six years of effort, only 19 of 523 hazardous waste land disposal facilities had received required EPA permits, three quarters had not yet completed applications. *Data on Waste Generation,*

and will continue to pose threats associated with the release of hazardous substances into the environment."[79]

Exclusions in federal hazardous waste regulation continue to allow disposal of some hazardous wastes at supposedly sanitary MSW disposal facilities. The Congressional Budget Office estimates that in 1983 alone over 26 million tons of hazardous waste were disposed of in what were supposed to be sanitary landfills.[80] In many municipalities wastewater treatment plant sludges are also disposed of at sanitary landfills; these sludges can remobilize at landfills to contaminate the groundwater.[81] EPA data suggest that at 169 sites surveyed where groundwater contamination occurred, sixty-five percent were forced to abandon their use of the groundwater and replace it with costly piped water.[82]

The OTA now acknowledges that hazardous substances are leaching from a significant percentage of sanitary solid waste facilities, and concludes that household waste is a source of these hazardous substances.[83] It is unclear whether a contaminated underground aquifer can ever be restored to yield drinkable water.[84]

Today's solutions are destined to become tomorrow's crises. Even total compliance with RCRA's groundwater protection standards[85] does not alleviate the significant public health and environmental risks posed by landfilling MSW. First, both MSW and industrial landfill facilities leak; the EPA estimates that more than half of the 2,000 interim-status land disposal waste facilities are leaking and will require remediation.[86] Second, RCRA imposes no sanctions against permitted hazardous facilities provided the facilities are *designed* not to leak, although they may in fact be leaking with impunity.[87] Third, owners of RCRA-permitted facilities remain liable for only thirty years after the facility is closed.[88] The EPA has concluded that it is "inevitable" that landfills will eventually leak;[89] however, after thirty years they leak at public rather than private expense. Fourth, a number of substances trigger legal liability under the federal cleanup statute (CERCLA)[90] that are neither monitored nor regulated by the federal long-term waste management statute (RCRA).[91] Moreover, on a practical level hazardous chemicals could be leaking into the groundwater from RCRA-permitted MSW facilities without violating the RCRA permit in any way. However, their spill, leakage, or even threat of leakage would trigger CERCLA's remedial mechanisms and penalties.[92]

Stated another way, RCRA does not require the monitoring of these CERCLA "hazardous substances" because under RCRA they are not deemed "hazardous wastes."[93] Further, RCRA regulations specify groundwater contamination detection levels that are far more lenient, sometimes one thousand times more lenient, than comparable CERCLA groundwater detection standards.[94] Yet if any of these hazardous chemicals leaks in excess of the reportable

Management Said Inadequate for Key Policy Decisions, 17 Env't Rep. (BNA) 1784, 1784 (Feb. 20, 1987).

90. 40 C.F.R. § 302.4 (1988).

91. 40 C.F.R. § 261.33 (1988). The most hazardous of these chemicals include carbofuran, chlorpyrifos, diazinon, dichlone, alpha-endosulfan, beta-endosulfan, endosulfan-sulfate, endrin aldehyde, guthion, mercaptodimethur, mevinphos, and naled. SUPERFUND STRATEGY, *supra* note 42, at 148.

92. *See infra* notes 195-218 and accompanying text for a discussion of CERCLA's remedial provisions.

93. SUPERFUND STRATEGY, *supra* note 42, at 148.

94. *Id.*

Using combined data, the OTA lists the following examples of hazardous chemicals with groundwater detection levels that are higher under RCRA than under CERCLA:

Pollutant	CERCLA detection levels (ng/l) + + +	RCRA detection levels (ng/l)
dieldrin	5	2,500 +
DDT	10	4,700 +
DDE	5	5,600 +
DDD	10	2,800 +
heptachlor	5	1,900 +
heptachlor epoxide	5	2,200 +
aldrin	5	1,900 +
antimony	20,000	32,000 + +
arsenic	10,000	53,000 + +
cadmium	1,000	4,000 + +
lead	5,000	42,000 + +
selenium	2,000	75,000 + +
thallium	10,000	40,000 + +

+ U.S. Environmental Protection Agency, *Test Methods for Evaluating Solid Waste Physical/Chemical Methods*, SW 846, 2d ed. (Washington, DC: Office of Solid Waste, EPA, 1982).

quantity under CERCLA,[95] CERCLA requires that the leak be reported, cleaned up, and disposed of by a RCRA-licensed hauler at a RCRA-licensed facility.[96]

This means that a number of MSW disposal facilities that presently comply with RCRA standards could eventually become Superfund sites subject to CERCLA.[97] Nationwide, there are more than 14,000 operating municipal and sanitary landfills, and about 42,000 closed municipal and sanitary landfills.[98] In addition, the OTA estimates that there are 75,000 operating and 150,000 closed industrial landfills, and 176,242 operating and 4,731 closed surface impoundments.[99] Of these 621,000 open and closed solid waste facilities, the OTA conservatively estimates that 17,400 to 34,800 MSW sites may eventually require cleanup under Superfund.[100] This estimate is eight to seventeen times larger than the EPA's projected 2,000-site NPL.[101] The problem is immense. The common law jurisprudence struggles to embrace the technical reality of a landfill crisis of national scope.

III. Playing the Numbers: Charles George Roulette

Nowhere is this phenomenon more dramatically illustrated than at the privately owned Charles George Landfill, now an EPA Superfund site. This large dumpsite is situated on approximately seventy acres, primarily in the town of Tyngsboro in northeastern Massachusetts.[102] Like many landfills and dumps, the Charles George Landfill is located on relatively low-lying swampy marsh, which is not well-suited for residential or commercial use. The landfilling of waste materials in these verdant areas readily allows

102. EPA, SUPERFUND RECORD OF DECISION: CHARLES GEORGE, MA 1 (July 11, 1985) [hereinafter CHARLES GEORGE ROD]. Technically the site is owned by the Charles George Land Reclamation Trust. *Id.* It is located on approximately 60 acres in the southwest corner of Tyngsboro and on nine adjoining acres in Dunstable, Massachusetts. *Id.* The owner also purchased 45 acres of forest land as a buffer to the south, between the landfill and the Cannongate Condominiums. *Id.*

the percolation of liquid leachate into the water-course and water table.

About half of the existing site was opened in 1955 as a privately owned dump for the disposal and burning of Tyngsboro's municipal refuse, operating under contract with the town.[103] Mr. Charles George purchased the dumpsite in July 1967, and within thirty months acquired adjacent parcels which expanded the contiguous land area to seventy acres.[104] The site continued to operate as a municipal dump, and in 1973 the Commonwealth of Massachusetts issued a permit allowing it also to accept hazardous wastes.[105] In accordance with its annually renewed license, from January 1973 to about June 1976 the Charles George landfill accepted drummed and bulk liquid hazardous wastes and municipal refuse.[106] The EPA estimates that during this four-year period, the landfill accepted approximately 2,500 cubic yards of hazardous chemical wastes.[107]

In 1974, during the period of hazardous waste disposal, the town of Tyngsboro issued permits for development of the Cannongate Condominiums adjacent to the Charles George Landfill, and granted permission to the developers to sink water wells for the condominiums.[108]

In May 1977, after all disposal of hazardous wastes had ceased, the Tyngsboro Board of Health rescinded the permits and disal-

103. *Id.* at 3, app. A at A-1. This dump was limited to accepting municipal refuse for the town of Tyngsboro. Evidence exists that between 1955 and 1967, although supposedly authorized to operate on 30 acres, municipal waste disposal actually took place on 63.3 acres.

104. *Id.* app. A at A-1. Interestingly, this expansion of land area to the west was away from Flint Pond, bordering wetlands and the Merrimack River. Formal approval to use the entire 63.3 acres was provided by Tyngsboro on May 25, 1976, although no public hearing was held until Sept. 21, 1976, after the decision. *Id.* at A-3.

105. *Id.* at 3. Beginning in May 1973, Charles George submitted monthly operating reports, which detailed the landfill operations, to the Massachusetts Hazardous Waste Board, Division of Water Pollution Control. *See id.* app. A at A-1.

106. *Id.* at 3. The operator submitted to the commonwealth monthly hazardous waste operations reports through calendar year 1979. *Id.* app. A at A-2 to A-6.

107. *Id.* at 3. There are no precise records revealing where on the 70 acre site the hazardous wastes were disposed. There are, however, persuasive indications that the hazardous chemical wastes were buried in the western segment of the site. During the time the permit was in effect, the landfill was operated only on the westernmost 38 acres of the current site. *See id.* app. A at A-3. It is therefore suspected that the chemical waste was buried in this area. Aerial photographs of the Charles George Landfill taken in 1973 and 1976 indicate trenches at the site's western end that may have been used for landfilling chemical waste. ECOLOGY & ENV'T, INC., FIELD INVESTIGATION OF UNCONTROLLED HAZARDOUS WASTE SITES/FIT PROJECT 2-3 (1982) (hydrogeologic study of Charles George Landfill vicinity prepared for EPA) (copy on file at the *George Washington Law Review*).

108. These condominiums comprise 96 units located about 500 feet south of the landfill. Other single-family residences are also within a 500 foot radius of the site. All were originally supplied by private drinking water wells. CHARLES GEORGE ROD, *supra* note 102, at 1.

lowed any dumping at the landfill.[109] Nonetheless, landfill operations continued to accommodate Tyngsboro's refuse. To remedy repeated alleged violations of Massachusetts environmental statutes, Charles George entered into a consent decree with the commonwealth requiring George to provide for leachate control, thereby allowing the site to continue operating as a sanitary MSW landfill.[110] In May 1979, based on water samples, the Tyngsboro Board of Health revoked its existing permits for the ninety percent of the site that operated within town boundaries and ordered the dump to close immediately.[111] However, there was apparently no enforcement of this order and the site continued to operate as a refuse dump, accepting garbage from Tyngsboro.[112]

In December 1980, volatile organic compound contamination was discovered in the wells serving the Cannongate Condominiums, and later contamination was discovered in numerous groundwater monitoring wells.[113] In October 1981, during CERCLA's first year of operation, the Charles George Landfill was listed as an EPA Superfund site.[114] Yet the site still continued to operate as a solid waste refuse dump for Tyngsboro. In April 1982, based on continuing alleged violations, some dating back to 1976 when the first government inspections were conducted,[115] the Tyngsboro Board of Health unanimously suspended the Charles George Landfill license until the landfill could remedy the outstanding violations.[116]

The commonwealth closed the Cannongate Condominium drinking water wells in July 1982.[117] Private water supplies were provided to residents, first by Charles George and later by an aboveground extension of a municipal water system.[118]

The landfill finally ceased accepting municipal waste in June

109. *Id.* app. A at A-4 (meeting of May 7, 1977).

110. *Id.* at A-5 (discussing the Consent Judgment of March 30, 1978). The decree provided for implementation of leachate control measures and development of an approved engineering plan for operation of the landfill. *Id.* The plan was approved by the Massachusetts Department of Environmental Quality Engineering (DEQE) on June 22, 1978. *Id.* at A-6.

111. *See id.* A June 18, 1980 letter from the Massachusetts DEQE noted a host of environmental violations, including open burning of trash, improper control of surface water runoff, improper compacting of refuse, and failure to cover slopes of refuse with surface cover. *Id.* at A-7. The Department initiated legal action for failure to comply with the consent judgment. *Id.*

112. *See id.* at A-6. In June and July of 1980, active acceptance of refuse was terminated temporarily because of a fire at the site. *Id.* at A-7. In July, the bond required for the landfill expired. Despite these occurrences, the landfill reopened for operation in August 1980. *Id.* at A-7 to A-8.

1983.[119]

Hazardous leachate from the Charles George Landfill flows into a brook that feeds a marshy pond, which recharges the area aquifer and flows into the Merrimack River. The Merrimack River is the drinking water source for three downstream communities.[120] The landfill site exhibits exposed MSW on a mottled terrain of steep slopes and valleys; the lack of cover allows for precipitation and infiltration of surface waters and generates an estimated 36 million gallons of leachate annually.[121] An on-site leachate collection system often malfunctions.

The EPA estimates that more than 9,300 pounds of VOCs and more than 188,000 pounds of toxic heavy metals annually migrate off-site into neighboring groundwater.[122] This leachate contains heavy concentrations of organic contaminants, along with inorganic contaminants at levels in excess of EPA drinking water standards, including arsenic, iron, aluminum, and manganese.[123] Additionally, gas venting from the landfill emits a wide range of VOCs, including known human carcinogens such as vinyl chloride and benzene.[124]

The EPA is pursuing site remediation that encompasses capping and grading of the site,[125] surface water collection and diversion,[126] venting of gas,[127] collection of leachate, and removal of remaining

119. CHARLES GEORGE ROD, *supra* note 102, at 4.

120. *Id.* at 2. Within the immediate site vicinity are several surface water resources that are affected by contamination at the site: Dunstable Brook, Bridge Meadow Brook, and Flint Pond. Sampling data of Dunstable Brook, west of the site, indicates the presence of contaminants from the landfill. Dunstable Brook flows in a southerly direction before flowing into Bridge Meadow Brook, which discharges into Flint Pond Marsh, which in turn supplies Flint Pond. Flint Pond is a shallow pond immediately east of the landfill. The total flow distance from the confines of Bridge Meadow Brook and Dunstable Brook to the tail water of Flint Pond is about two-thirds of a mile. Sample results indicate contamination of the marsh, which is the headwater for Flint Pond proper. Flint Pond is used for recreational purposes, such as fishing, boating, and swimming. Moreover, there are 16 residences along the northern shore that use shallow wells next to the pond as their drinking water supply. The outlet of the pond discharges into the Merrimack River, further east of the site, which is the drinking water source for the downstream communities of Lowell, Lawrence, and Methuen. *See generally id.* at 1-2 (describing the landfill location and nearby water sources).

121. *Id* at 4-5.

122. *Id* at 5.

123. *See id* at Table 1 (Summary of Leachate Contaminants, Charles George Site). Organic contaminants include vinyl chloride, methylene chloride; acetone; 1,1-dichloroethane; trans-1,2-dichloroethane, 2-butanone, 4-methyl, 2-pentanone; toluene; ethyl benzene; phenol; 4-methylphenol, and benzoic acid

solid waste dumpsters.[128] Faced with several options, the EPA elected to cap the entire site with an expensive, untried, synthetic membrane,[129] which the EPA estimates will cost $12 million.[130] The cost of the other remediation measures is estimated to be almost $2 million, plus about $70,000 annually in operation and maintenance expenses.[131] The potentially responsible parties at this site estimate that the cost of remediation will approach $30 million.[132]

The EPA identified more than thirty potentially responsible parties (PRPs) who allegedly generated the 2,500 cubic yards of hazardous industrial waste disposed at the landfill between January 1973 and July 1975.[133] The EPA demanded that these private PRPs pay the entire cost of site remediation, provide alternative water supplies, and cover the cost of putting a synthetic cap over the entire seventy-acre site. The PRPs raised a number of engineering and economic objections to the EPA's decision to require the PRPs to put an untried synthetic membrane over the entire site, and also raised legal, factual, and equitable objections to the EPA's assignment of liability.[134]

In their factual objections the PRPs pointed out that only 0.06% of the volume of waste at Charles George qualifies as privately contributed hazardous industrial waste;[135] 99.9% of the volume is MSW generated primarily by Tyngsboro or other communities. The EPA has not allowed the PRPs to isolate the geographic region in which the hazardous wastes were likely buried,[136] but rather has proceeded with remediation. In addition, the EPA has failed to name as defendants the Town of Tyngsboro or any other contributors of MSW or commercial refuse.[137] Confronted with lone responsibility as a consequence of contributing less than 0.1% of the gross volume of waste, the PRPs have refused to settle with the EPA, pointing out

128. *Id.* at 13. The leachate collection system employs a peripheral slotted pipe which collects leachate and transports it to two collection dumps, where it is trucked offsite to a licensed treatment facility. *Id.*

that waste disposal at Charles George was always subject to state licensed permission and supervision.[138] Although no court has yet directly confronted the issue, there is reason to believe that if this issue proceeds to trial, the outcome may be contrary to EPA's position.

If MSW were a hazardous substance, the court would be required to apportion the cleanup share equitably between the public (municipalities) and private concerns.[139] Assuming that household waste is 0.1% hazardous by volume,[140] the hazardous component of the four million cubic yards of MSW at Charles George would net about 4,000 cubic yards, almost twice the volume of hazardous industrial waste contributed by the private PRPs. A sixty-forty MSW-private waste split of a possible $30 million cleanup responsibility at the Charles George site would still impose a significant economic burden on the more than thirty private PRPs, and would cripple Tyngsboro or even a combination of municipalities.

The Charles George case presents a graphic illustration of the real-world implications of the debate over MSW liability. At stake in this numbers game are millions of dollars of liability at thousands of sites across the nation. More fundamentally, whether public treasuries from Texas to Tyngsboro will be opened to clean up the nation's hazardous waste in a game of toxic roulette is also at stake.

IV. Absorbing Toxic Shock: The Legal Fabric

A. RCRA and CERCLA

The basic legal guidelines for regulating hazardous waste sites are embodied in two federal statutes: the Resource Conservation and Recovery Act of 1976 (RCRA)[141] and the Comprehensive Environmental, Response, Compensation and Liability Act of 1980 (CERCLA), commonly known as the "Superfund."[142] While RCRA regulates the handling of solid and hazardous waste from its generation to final disposal,[143] CERCLA authorizes the government to impose and allocate the costs incurred for the cleanup of designated hazardous sites.[144]

Most RCRA waste management regulations apply solely to pres-

138. *See* Ferrey, *supra* note 132, at 9.

139. Although legal liability at Superfund sites is joint, several, and strict, principles of equitable contribution also apply. *See infra* text accompanying notes 352-62.

140. *See supra* text accompanying notes 55-56.

144. *Id.* §§ 9601-9607.

ent and future disposal activities, and not to prior waste disposal activities at inactive sites that cause current problems.[145] However, RCRA section 7003, as amended in 1984,[146] allows the EPA to seek restitution for all cleanup response costs incurred to remedy current imminent hazards due to "past or present" activities.[147] Therefore, recent court decisions hold that RCRA may apply to inactive sites when current releases constitute a present danger.[148]

CERCLA was enacted in response to increasing concern over the problems of hazardous waste disposal.[149] CERCLA supplements RCRA by giving the government a means to take action against current problems created by past improper disposal practices.[150] CERCLA section 104[151] authorizes a government response when those responsible for a hazardous waste site are unavailable or the site is abandoned.[152] CERCLA section 107[153] allows the EPA to recover response costs for the cleanup of hazardous waste disposal which occurred at any time.[154] As one court has explained:

> There can be little doubt that [CERCLA] sections 104 and 107(a) were intended to apply retroactively. A brief review of the case law and legislative history clearly supports this proposition. It was the precise inadequacies resulting from RCRA's lack of applicability to inactive and abandoned hazardous waste disposal sites that prompted the passage of CERCLA.[155]

145. *E.g.*, United States v. Waste Indus., 556 F. Supp. 1301, 1307 (E.D.N.C. 1982) (holding that RCRA is not applicable to inactive or abandoned sites); Comment, *Private Response-Cost Recovery Actions Under CERCLA*, 34 U. KAN. L. 1. The Superfund

CERCLA established the Hazardous Substance Response Trust Fund, commonly known as the "Superfund."[156] The Superfund is used to pay for governmental response to actual and threatened releases of hazardous substances, necessary response costs incurred by any other person, and natural resource damage claims.[157] Under section 104 the government may use the Superfund whenever (1) any hazardous substance is released or there is a substantial threat of release; or (2) there is a release or substantial threat of release of any "pollutant or contaminant" that may present an imminent and substantial danger to the public health or welfare.[158] If the President determines, however, "that such [remedial] action will be done properly and promptly by the owner or operator of the facility" from which the release or threat of release emanates, or by any other responsible party, he may allow such party to carry out the action.[159]

Revenues for the original $1.6 billion trust fund were derived from sales taxes on chemical corporations, although one eighth of the Superfund's financing came from general appropriations.[160] With the passage of the Superfund Amendments and Reauthorization Act of 1986 (SARA),[161] Congress provided an $8.5 billion five-year reauthorization for the Superfund, and also expanded the

Mo. 1984) (applying CERCLA to past generators and transporters), *aff'd in relevant part, rev'd in part*, 810 F.2d 726 (8th Cir. 1986), *cert. denied*, 108 S. Ct. 146 (1987); *see also* Ohio *ex rel.* Brown v. Georgeoff, 562 F. Supp. 1300, 1314 (N.D. Ohio 1983) (applying CERCLA to past transporters); Jones v. Inmont Corp., 584 F. Supp. 1425, 1428 (S.D. Ohio 1984) (holding that CERCLA imposes liability on past generators of hazardous waste); *cf.* United States v. Northeastern Pharmaceutical & Chem. Co. (*NEPACCO II*), 810 F.2d 726, 749 (8th Cir. 1986) (holding that response costs incurred prior to CERCLA's enactment are also recoverable), *cert. denied*, 108 S. Ct. 146 (1987); United States v. Wade, 14 Envtl. L. Rep. (Envtl. L. Inst.) 20,437 (E.D. Pa. Mar. 22, 1984) (holding that CERCLA imposes liability for response costs incurred before promulgation of the National Contingency Plan (NCP), but not prior to CERCLA's enactment).

156. 42 U.S.C. § 9631(a) (1982), *repealed by* Superfund Amendments and Reauthorization Act of 1986 (SARA), Title V, § 517(c)(1), 100 Stat. 1613, 1774. For a discussion of SARA's implications for the Superfund, see *infra* notes 161-62 and accompanying text.

157. *See* 42 U.S.C. § 9611 (1982 & Supp. IV 1986). The Superfund is not used for natural resource damage claims in any year when the Superfund is needed to respond to public health threats. *See id.* § 9611(c) (Supp. IV 1986).

158. *Id.* § 9604(a)(1).

159. *Id.*

160. ALI-ABA COURSE OF STUDY, HAZARDOUS WASTES, SUPERFUND, AND TOXIC SUBSTANCES 31-32 (1983); Comment, *supra* note 145, at 114.

161. Pub. L. No. 99-499, 100 Stat. 1613 (codified as amended in scattered sections of 42 U.S.C. and the I.R.C.).

Superfund's tax base.[162] The Superfund enables the EPA, when necessary, to respond quickly to a hazardous waste release.[163] The government then acquires the right, subject to a lien on the affected property, to seek reimbursement from PRPs for costs incurred for cleanup, oversight, administration, legal removal, and resource restoration.[164] The reimbursed money is used to replenish the Superfund.[165]

Before the EPA is allowed to spend Superfund monies for remedial action, certain conditions must be met. First, the site must be included on the National Priority List (NPL).[166] Operating under the National Contingency Plan (NCP), the NPL lists facilities that are priorities for remedial action and, as much as practicable, for removal action.[167]

Second, the affected state must enter into a cooperative agreement to pay at least ten percent of the costs of the remedial action.[168] However, if the site is owned and operated by the state or one of its political subdivisions or contractors, the state or subdivision must pay at least fifty percent of the response costs, or a greater amount as the President deems appropriate considering the degree of state or subdivision responsibility for the release.[169] In addition,

162. SARA § 111, 42 U.S.C. § 9611 (Supp. IV 1986). The new tax is composed of a $2.75 billion petroleum excise tax, *id.* § 512, I.R.C. § 4611; a $1.4 billion excise tax on feedstock chemicals, *id.* § 515, I.R.C. §§ 4661-4662; a $57 million tax on imported chemical derivatives, *id.* § 515, I.R.C. §§ 4671-4672; a new $2.5 billion environmental tax on corporate alternative minimum taxable income, *id.* § 516, I.R.C. § 59A; $1.25 billion from general revenues, *id.* § 517, I.R.C. § 9507; plus a special $500 million tax on gasoline and motor fuels to fund correction of leaking underground storage tanks, *id.* §§ 521-522, I.R.C. §§ 4081, 9508. *See generally* H.R. CONF. REP. No. 962, 99th Cong., 2d Sess. 344 (containing a table of estimated revenues from the 1986 Superfund Amendments for fiscal years 1987-1992), *reprinted in* 1986 U.S. CODE CONG. & ADMIN. NEWS 3276, 3437.

163. CERCLA does not authorize governmental response to releases from consumer products. ALI-ABA COURSE OF STUDY, HAZARDOUS WASTES, SUPERFUND, AND TOXIC SUBSTANCES 6 (1982) [hereinafter 1982 ALI-ABA COURSE OF STUDY].

164. 42 U.S.C. §§ 9607(l)-(m), 9612(c)(1)-(3) (1982 & Supp. IV 1986). This lien is subordinate to preexisting liens perfected before notice or filing of the government lien. *Id.* § 9607(l) (Supp. IV 1986).

165. *Id.* § 9612(c)(3) (1982).

166. 40 C.F.R. § 300.66(c)(2) (1988); *see also id.* pt. 300, app. B (listing sites included on the NPL); McChesney, *supra* note 149, at 10,042 (citing 47 Fed. Reg. 10,992 (1982) (codified at 40 C.F.R. § 300.67(a) (1988))).

167. 42 U.S.C. § 9605(a)(8)(A) (Supp. IV 1986). The states are primarily responsible for deciding which releases are priorities. Upon submission of these priority lists to the EPA, the EPA consolidates them into the NPL. At least one site from each state will, as far as practicable, be ranked in the top 100. *Id.* § 9605(a)(8)(B). The criteria for determining priority are based on

> [the] relative risk or danger to public health or welfare or the environment . . . taking into account to the extent possible the population at risk, the hazard potential of the hazardous substances at such facilities, the potential for contamination of drinking water supplies, the potential for direct human contact, the potential for destruction of sensitive ecosystems . . . State preparedness to assume State costs and responsibilities, and other appropriate factors.

Id. § 9605(a)(8)(A).

168. *Id.* § 9604(c)(3)(C)(i).

169. *Id.* § 9604(c)(3)(C)(ii). As a practical matter, the EPA demands no more than the applicable 10% or 50% share. If a federal facility is responsible for the release of hazardous waste, however, Superfund monies may not be used for remedial action. 1982 ALI-ABA COURSE OF STUDY, *supra* note 163, at 11.

170. 42 U.S.C. § 9604(c)(3)(A)-(B) (Supp. IV 1986). The federal government is increasingly categorizing more expenses as "remedial" rather than "maintenance" to alleviate any cash burden on states.

171. *See* 42 U.S.C. § 9605 (Supp. IV 1986); Exec. Order No. 12,580, 3 C.F.R. 193 (1987) (delegating responsibility for revision of the NCP and other duties under § 9605 to the EPA), *reprinted in* 42 U.S.C. § 9615 app. note at 1054 (Supp. IV 1986).

172. *See* OFFICE OF EMERGENCY & REMEDIAL RESPONSE, EPA, THE EFFECTIVENESS OF THE SUPERFUND PROGRAM: CERCLA SECTION 301(a)(1)(A) STUDY 1-5, 1-8 (1984) (Final Report). As of 1984, 10,700 sites had preliminary assessments completed; 3,600 sites had inspection completed; and 1,700 sites were scored for NPL ranking. *Id.* at E-3.

About five percent of the CERCLIS sites are placed on the NPL and become eligible for cleanup. *See id.* at 1-13 (stating that as of 1984, 538 sites from CERCLIS's inventory of 10,700 were listed on the NPL). The CERCLIS inventory, as of February 1989 containing slightly over 30,000 sites, continues to grow as new sites are investigated. Telephone Inquiry to CERCLIS Hotline (Feb. 10, 1989).

CERCLIS, originally known as the Emergency and Remedial Response Information System (ERRIS), is an information tracking system for potentially hazardous sites. There is no formal publication of this tracking system. One may gain access to CERCLIS data either by contacting the EPA headquarters or regional offices, or by calling the CERCLIS hotline at (202) 252-0056.

173. By the end of fiscal year 1982, the EPA had initiated only 54 remedial investigations and feasibility studies (RI/FSs); by the end of fiscal year 1984, a total of 315 RI/FSs were begun, of which over 82% had been initiated since the beginning of fiscal year 1983. OFFICE OF EMERGENCY & REMEDIAL RESPONSE, EPA, *supra* note 172, at 1-27 & Exhibit 1-5 (Superfund Program: Remedial Investigation and Feasibility Studies). In fiscal year 1982, EPA initiated 57 removal actions; in fiscal year 1984, 204 were initiated. *Id.* at 2-22 (Exhibit 2-5. Superfund Removals Initiated by Fiscal Years). By the end of fiscal year 1984, the Superfund financed remedial design activities at 34 sites and remedial construction at 29 sites. In addition, PRPs initiated remedial design and construction at 22 sites. *Id.* at 1-32 to 1-33.

174. SARA § 116, 42 U.S.C. § 9616 (Supp. IV 1986). It is expected that the President will add 1,600-2,000 sites to the NPL by 1988. H.R. CONF. REP. No. 962, 99th Cong., 2d Sess. 229 (1986). Within 36 months of SARA's October 1986 passage, 275 RI/FSs are to be commenced. 42 U.S.C. § 9616(d) (Supp. IV 1986). Within 36 months the President is also directed to begin remediation at an additional 175 sites; within 24

the state must assume all future site maintenance costs and must provide a proper hazardous waste disposal facility in-state to receive any transported hazardous substances.[170]

2. *EPA Administration*

The EPA is charged with assessing all potential hazardous waste sites for remedial action.[171] The EPA performs a preliminary assessment off-site to determine general priorities among sites, and the information is filed in the Comprehensive Environmental Response, Compensation and Liability Information System (CERCLIS), an EPA inventory of hazardous waste sites.[172] Although the EPA's pace has accelerated, the Superfund program has been slow to initiate and complete remedial actions,[173] even though the recent Superfund amendments impose stringent time schedules.[174]

The EPA employs a Hazard Ranking System (HRS) to score the

potential risk presented by various sites to determine which qualify for priority ranking on the NPL.[175] This score assigns to each site a relative numerical value, based on the risk posed by hazardous substances and the imminence of that risk.[176] Only when a site is placed on the NPL by virtue of a high HRS score is it eligible for EPA remedial action.[177]

Although the NCP provides extensive guidance for selecting an appropriate remedial action plan, it does not dictate how clean a site must become to satisfy Superfund criteria.[178] The 1986 Superfund Amendments, for the first time, mandate that the extent of cleanup must meet or exceed the standards applicable to other federal public health and environmental statutes.[179] If material is removed for disposal off-site, the material must be handled and contained in a manner consistent with RCRA;[180] containment on-site must comply with the Clean Air Act,[181] the Clean Water Act,[182] and the Safe

months after this, the President is expected to commence on-site remediation at 200 additional sites. *Id.* § 9616(e).

175. OFFICE OF EMERGENCY & REMEDIAL RESPONSE, EPA, *supra* note 172, at 1-11 to 1-12. The 1986 Superfund amendments require the President, within 24 months, to promulgate new hazardous ranking system (HRS) procedures proposed by the EPA. 42 U.S.C. § 9605 (Supp. IV 1986). The proposed revision of HRS is presented at 52 Fed. Reg. 11,513 (1987). The HRS must adequately evaluate toxicity, quantity, and concentration of wastes under the 1986 Amendments. *Id.*

176. An HRS score of 28.5, which reflects a combined value of three categories of ranking for ground water, surface water, and air threat, is sufficient to place a site on the NPL in its rank order. If a leaking site is close to surface water, buildings, or populations, its HRS score is increased. These criteria are proxies, if inexact proxies, for the threat posed to human health and the environment. *See* OFFICE OF EMERGENCY & REMEDIAL RESPONSE, EPA, *supra* note 172, at 1-11 to 1-13 & n.5; *see also* 42 U.S.C. § 9605(c) (Supp. IV 1986) (establishing the hazard ranking system to assess the relative degree of risk posed by sites under review).

177. Office of Emergency & Remedial Response, EPA, *supra* note 172, at 1-16.

178. When a site is placed on the NPL, the EPA may have only a rudimentary data base about the nature of the problem presented by the site. The EPA will also have done little or no work in determining which type of cleanup actions may be appropriate at the site. This knowledge base is acquired during the Remedial Investigation, which may well follow after the site is designated an NPL site. *See generally* 40 C.F.R. § 300.68(d) (1988) (requiring a Remedial Investigation/Feasibility Study (RI/FS) to gather sufficient information to determine the nature of the threat and the extent of necessary remedial action); *infra* notes 184-86 and accompanying text (discussing the RI/FS procedures).

179. SARA § 121, 42 U.S.C. § 9621(d) (Supp. IV 1986). The Superfund Amendments direct the President to ensure compliance with the Safe Drinking Water Act, Pub L. No. 93-527, 88 Stat. 1660 (1974) (codified as amended predominantly in scattered sections of 42 U.S.C.), and the Clean Water Act, 33 U.S.C.A. §§ 1251-1387 (West 1986 & Supp. 1988). *See* SARA § 121, 42 U.S.C. § 9621(d) (Supp. IV 1986).

180. *See* SARA § 121, 42 U.S.C. § 9621(d)(3) (Supp. IV 1986); *see also infra* text accompanying notes 384-404 (outlining RCRA's provisions).

181. 42 U.S.C. §§ 7401-7642 (1982 & Supp. IV 1986). This Act regulates only a few of the scores of chemicals present at Superfund sites. The Act regulates only chemicals that, via the medium of air, pose a risk through inhalation. *See also* SARA § 121, 42 U.S.C. § 9621(d)(2) (Supp. IV 1986) (providing that hazardous substances remaining onsite must meet the standards of the Clean Air Act).

182. 33 U.S.C.A. §§ 1251-1387 (West 1986 & Supp. 1988). This Act regulates only chemicals present in surface water. However, leaking hazardous waste landfills pose an additional risk to groundwater. *See* SARA § 121, 42 U.S.C. § 9621(d) (Supp. IV 1986) (providing that remedial action must meet the water quality criteria of the Clean Water Act).

Drinking Water Act.[183] Although each of these federal statutes provides specific standards, each affects only one medium and route of exposure to hazardous constituents; there is no comprehensive multi-media regulation.

The EPA conducts a Remedial Investigation/Feasibility Study (RI/FS) for each site.[184] The RI/FS consists of two studies: the first characterizes environmental conditions at the site;[185] the second details a series of engineering alternatives for site remediation.[186] Based on alternatives developed in the RI/FS, the EPA must select an appropriate cleanup option after considering cost, technology, reliability, and their relevant effects on public health.[187] This determination is set forth in the EPA Record of Decision (ROD).[188] If PRPs negotiate a voluntary cleanup with the EPA, they can conduct and control much of the work which would otherwise be undertaken by the EPA.[189] There can be significant cost-savings to PRPs who voluntarily assume the cleanup responsibility.[190]

Under CERCLA section 104, as amended by SARA, remedial or removal actions are not required if the President determines that such actions will be done properly by any "responsible" party.[191] Furthermore, in the absence of state cost-sharing, the EPA must cease its response action after either $2 million has been spent or twelve months have passed since the response was initiated.[192]

183. Pub. L. No. 93-527, 88 Stat. 1660 (1974) (codified as amended predominantly in scattered sections of 42 U.S.C.). This Act sets standards only for drinking water supplies, which are not always affected at Superfund sites, and then only for compounds that cause significant risk to human health through a pathway of ingestion. The health advisories issued under the Act consider short-term impacts, and do not consider long-term carcinogenic results. The 1986 Superfund Amendments take special cognizance of protecting drinking water supplies. *See* SARA §§ 118, 121, 42 U.S.C. §§ 9618, 9621 (Supp. IV 1986).

184. 40 C.F.R. § 300.68(d) (1988).

185. The Remedial Investigation indentifies the source and extent of contamination and pathways of possible migration or release into the environment. It also identifies the potential environmental or human risks. *Id.*

186. The Feasibility Study details alternatives for cleanup, with estimates of costs and environmental impact. *Id.*

187. *Id.* § 300.68(i).

188. The ROD selects an alternative and then subjects it to public comment before finalizing the choice. *Id.* § 300.67(d).

189. *See* 42 U.S.C. §§ 9604, 9622 (Supp. IV 1986); 50 Fed. Reg. 5034-44 (Feb. 5, 1985); Stoll & Graham, *Need for Changes in EPA's Settlement Policy*, 1 NAT. RESOURCES & ENV'T 7, 7 (1985).

190. According to a September 1986 report by the EPA Inspector General, the EPA experiences serious cost-control problems when it oversees remediation. *Current Developments*, 18 Env't Rep. (BNA) 4, 4-5 (May 1, 1987); *see also* Anderson, *Negotiation and Informal Agency Action: The Case of Superfund*, 1985 DUKE L.J. 261, 301-02 (noting that cleanup costs incurred by EPA might average 30-40% more than those incurred by PRPs).

191. 42 U.S.C. § 9604(a)(1) (Supp. IV 1986)

192. SARA § 104(c), 42 U.S.C. § 9604(c)(1) (Supp. IV 1986) (doubling the dollar amount and time for response that existed in CERCLA as originally enacted).

However, these limits are extended if the EPA determines that "(i) continued response actions are immediately required to prevent, limit, or mitigate an emergency, (ii) there is an immediate risk to public health or welfare or the environment, and (iii) such assistance will not otherwise be provided on a timely basis."[193] In addition, section 104 empowers the EPA to investigate and demand any information needed to determine the extent of the problem.[194]

B. *CERCLA's Legal Tools*

CERCLA's legal mechanisms are activated when there is a release[195] or threatened release of a hazardous substance[196] from a waste facility, which causes the "incurrence of response costs."[197] Persons in charge of a facility must notify the National Response Center (NRC) as soon as they are aware of any hazardous substance release that equals or exceeds the reportable quantity established for that substance under CERCLA section 103.[198] The NRC need not be notified if such release is a federally permitted release,[199] although state and federal permits may require the reporting of certain releases to the NRC.[200] A fine in accordance with U.S. Code title 18 or imprisonment for up to three years (or up to five years for a second or subsequent conviction) is imposed for failure to provide

193. *Id.*.

194. *Id.* § 9604(e)(2). PRPs are required to respond to information requests from the EPA. *Id.*; *see also* United States v. Charles George Trucking Co., 624 F. Supp. 1185, 1187-88 (D. Mass. 1986) (discussing the permissible scope of information requests under 42 U.S.C. § 9604(e)(2)).

195. CERCLA defines "release" as "any spilling, leaking, pumping, pouring, emitting, emptying, discharging, injecting, escaping, leaching, dumping, or disposing into the environment." 42 U.S.C. § 9601(22) (Supp. IV 1986).

196. Hazardous substances are broadly defined to include those chemicals listed as hazardous under provisions other environmental statutes, namely: RCRA, 42 U.S.C. § 6903(5), 6921 (1982); the Clean Water Act; 33 U.S.C. § 1321 (b)(2)(A) (1982); the Clean Air Act, 42 U.S.C. § 7412(a)(1) (1982); the Toxic Substances Control Act, 15 U.S.C. § 2602(2)(A), (9) (1982); and CERCLA, 42 U.S.C. § 9601(14) (Supp. IV 1986). The EPA may designate as hazardous additional substances if their release "may present substantial danger to the public health or welfare or the environment." *Id.* § 9602(a).

197. 42 U.S.C. § 9607(a)(4) (Supp. IV 1986). The term "facility" includes:

> (A) any building, structure, installation, equipment, pipe or pipeline (including any pipe into a sewer or publicly owned treatment works), well, pit, pond, lagoon, impoundment, ditch, landfill, storage container, motor vehicle, rolling stock, or aircraft, or (B) any site or area where a hazardous substance has been deposited, stored, disposed of, or placed, or otherwise come to be located; but does not include any consumer product in consumer use or any vessel.

Id. § 9601(9); *see also infra* note 223 (discussing the broad construction of the term "facility").

198. 42 U.S.C. § 9603(a) (1982); *see* 40 C.F.R. § 302.6 (1988); 50 Fed. Reg. 13,456, 13,456-65 (1985). Final regulations for all reportable quantities must be published by April 30, 1988. SARA § 102, 42 U.S.C. § 9602 (Supp. IV 1986).

199. *See* 40 C.F.R. § 302.6 (1988); 50 Fed. Reg. at 13,456-65; *see also* 42 U.S.C. § 9601(10) (Supp. IV 1986) (defining "federally permitted release").

200. For example, discharge permits issued pursuant to the Clean Air Act, 42 U.S.C. §§ 7401-7642 (1982 & Supp. IV 1986), or the Clean Water Act, 33 U.S.C.A. §§ 1251-1387 (West 1986 & Supp. 1988), can require the reporting of releases in excess of those allowed by the permit.

timely notice.[201]

CERCLA endows the EPA with two primary tools for responding to the release or threatened release of a hazardous substance. The EPA may either (1) commence a response action under section 104,[202] or (2) initiate an enforcement action under section 106.[203]

1. *EPA Response Actions: Section 104*

Under section 104 the EPA is authorized to take direct actions, consistent with the NCP, to abate the pollution from a release or substantial threatened release of a hazardous substance,[204] or from a release or substantial threatened release of any "pollutant or contaminant."[205] Before the government may initiate a response action, however, there must exist an imminent and substantial threat to the public health or welfare.[206] If a responsible party is later found, both the federal and state governments, or any other person incurring cleanup costs consistent with the NCP, may seek reimbursement under section 107.[207]

The EPA is given broad authority under section 104.[208] The EPA may take short-term removal action[209] to stop the immediate threat

201. 42 U.S.C. § 9603(b) (1982 & Supp. IV 1986); *see also* SARA § 109(c), 42 U.S.C. § 9609 (Supp. IV 1986) (authorizing various civil penalties and awards).

202. 42 U.S.C. § 9604 (Supp. IV 1986). "'[R]esponse' means remove, removal, remedy, and remedial action." *Id.* § 9601(25). For the definition of "removal action," see *infra* note 209.

203. *Id* § 9606. *See generally CERCLA 1985: A Litigation Update*, 15 Envtl. L. Rep. (Envtl. L. Inst.) 10,395, 10,396 (1985) [hereinafter *CERCLA 1985*] (describing the injunctive relief available under CERCLA section 106 and the penalties for noncompliance).

204. 42 U.S.C. § 9604(a)(1) (Supp. IV 1986). The 1986 Superfund amendments clarify that "release" includes "the abandonment or discarding of barrels, containers, and other closed receptacles containing any hazardous substance or pollutant or contaminant." SARA § 101(22), 42 U.S.C. § 9601(22) (Supp. IV 1986).

205. 42 U.S.C. § 9604(a)(1) (Supp. IV 1986). The term "pollutant or contaminant" includes, but is not limited to:

> any element, substance, compound, or mixture, including disease-causing agents, which after release into the environment and upon exposure, ingestion, inhalation, or assimilation into any organism, either directly from the environment or indirectly by ingestion through food chains, will or may reasonably be anticipated to cause death, disease, behavioral abnormalities, cancer, genetic mutation, physiological malfunctions (including malfunctions in reproduction) or physical deformations, in such organisms or their offspring; except that the term "pollutant or contaminant" shall not include petroleum, including crude oil or any fraction thereof which is not otherwise specifically listed or designated as a hazardous substance under [section 9601(14)(A)-(F)] and shall not include natural gas, liquefied natural gas, or synthetic gas of pipeline quality (or mixtures of natural gas and such synthetic gas).

Id § 9601(33).

206. *Id* § 9604(a)(1).

207. *Id* § 9607(a).

208. *See CERCLA 1985*, *supra* note 203, at 10,397-98.

209. Removal actions are defined as:

posed by the release,[210] long-term remedial action to remedy the entire environmental contamination,[211] or a combination of both. These long- and short-term cleanup measures, however, must comport with the NCP.[212]

2. *EPA Imminent Hazard Authority: Section 106*

The imminent hazard authority of CERCLA section 106 provides

---

the cleanup or removal of released hazardous substances from the environment, such actions as may be necessary taken in the event of the threat of release of hazardous substances into the environment, such actions as may be necessary to monitor, assess, and evaluate the release or threat of release of hazardous substances, the disposal of removed material, or the taking of such other actions as may be necessary to prevent, minimize, or mitigate damage to the public health or welfare or to the environment, which may otherwise result from a release or threat of release.

42 U.S.C. § 9601(23) (Supp. IV 1986). In addition, the term "removal action" includes "action taken under section 9604(b) of this title." *Id.*; *see also* SARA § 104(b), 42 U.S.C. § 9604(b) (Supp. IV 1986) (providing that the EPA may make additional studies and investigations in connection with hazardous releases or threats thereof).

210. 42 U.S.C. § 9604(a)(1) (Supp. IV 1986). Actions taken under section 104(b) of CERCLA, as incorporated in the definition of "removal actions," include:

> [u]ndertak[ing] such investigations, monitoring, surveys, testing, and other information gathering as [the President] may deem necessary or appropriate to identify the existence and extent of the release or threat thereof, the source and nature of the hazardous substances, pollutants or contaminants involved, and the extent of danger to the public health or welfare or to the environment. In addition, the President may undertake such planning, legal, fiscal, economic, engineering, architectural, and other studies or investigations as he may deem necessary or appropriate to plan and direct response actions, to recover the costs thereof, and to enforce the provisions of this chapter.

Id. § 9604(b)(1).

Given this broad definition of "removal actions" and its inclusion in the statutory section authorizing "response," the courts have found the following to be "response costs" recoverable under section 107(a):

(1) The costs of investigations, monitoring, and testing to identify the nature and extent of the release or threatened release, *see* New York v. Shore Realty Corp., 759 F.2d 1032, 1043 (2d Cir. 1985); United States v. Conservation Chem. Co., 619 F. Supp. 162, 186 (W.D. Mo. 1985); Colorado v. ASARCO, Inc., 616 F. Supp. 822, 829 (D. Colo. 1985); New York v. General Elec. Co., 592 F. Supp. 291, 297-99 (N.D.N.Y. 1984); United States v. Northeastern Pharmaceutical & Chem. Co. (*NEPACCO I*), 579 F. Supp. 823, 850 (W.D. Mo. 1984), *aff'd in relevant part, rev'd in part*, 810 F.2d 726 (8th Cir. 1986), *cert. denied*, 108 S. Ct. 146 (1987);

(2) The costs of investigations, monitoring, and testing to identify the extent of the danger to public health or welfare or the environment, *see Shore Realty Corp.*, 759 F.2d at 1043; *Conservation Chem. Co.*, 619 F. Supp. at 186; *NEPACCO I*, 579 F. Supp. at 850; and

(3) The costs of planning and implementing the response action, *see Shore Realty Corp.*, 759 F.2d at 1043; *Conservation Chem. Co.*, 619 F. Supp. at 186; *NEPACCO I*, 579 F. Supp. at 850.

211. 42 U.S.C. § 9604(a)(1) (Supp. IV 1986); *see id.* § 9601(24) (defining "remedy" and "remedial action"). Long-term remediation efforts undertaken by the EPA must involve only those sites on the National Priority List. *See Shore Realty Corp.*, 759 F.2d at 1046. This long-term method is favored by the recent Superfund Amendments. *See* SARA § 121, 42 U.S.C. § 9621(b) (Supp. IV 1986).

212. 42 U.S.C. § 9604(a)(1) (Supp. IV 1986). The burden is on the complaining party to demonstrate that an EPA action is not consistent with the NCP. *Cf.* United States v. Northeastern Pharmaceutical & Chem. Co. (*NEPACCO II*), 810 F.2d 726, 747-48 (8th Cir. 1986) (stating that response costs incurred by the government are conclusively presumed to be "reasonable," because CERCLA § 107(a)(4)(A), 42 U.S.C. § 9607(a)(4)(A) (Supp. IV 1986) "does not refer to 'all *reasonable* costs' but simply to 'all costs'" (emphasis supplied by the court)), *cert. denied*, 108 S. Ct. 146 (1987).

the EPA with a second principal enforcement tool.[213] Upon the EPA's determination that an "imminent and substantial endangerment to the public health or welfare or the environment" is posed by "an actual or threatened release of a hazardous substance from a facility," the EPA is authorized to take such action "as may be necessary to protect public health and welfare and the environment," after the affected state is notified.[214] Under section 106, therefore, the EPA may compel responsible parties to abate releases or threatened releases of hazardous materials, by requesting the Attorney General to seek relief in federal district court (section 106 civil action), or by issuing such orders as may be necessary to protect the public (section 106 administrative orders).[215]

It is the EPA's practice, whenever possible, to allow those responsible for a release or threatened release to undertake the cleanup, thereby preserving limited CERCLA funds for other problem sites.[216] The district court may fine those who willfully violate or fail to comply with a section 106 order up to $25,000 per day.[217] In addition, responsible parties who, "without sufficient cause," fail to comply with a section 104 or 106 order may be held liable for punitive damages three times the amount of response costs incurred by the government as a result of the failure to comply.[218]

Although not originally specified in CERCLA, the EPA in practice employs a third alternative. Because of the considerable power granted to the government under sections 106 and 107, the EPA is in a strong position to encourage voluntary cleanups through informal negotiations and settlement.[219] This additional enforcement method embodies the EPA's policy of forcing those responsible for hazardous substance releases to take voluntary action as often as possible.[220]

3. *CERCLA Liability: Section 107*

Section 107, CERCLA's liability provision, attaches liability for (1) all removal or remedial costs incurred by federal or state governments that are not inconsistent with the national contingency plan;[221] (2) "any other necessary costs of response incurred by any

---

213. 42 U.S.C. § 9606 (1982 & Supp. IV 1986).

214. *Id.* § 9606(a) (1982).

215. *Id.* Section 106 directs the federal courts to use their equitable powers to cause those responsible to abate the danger caused by the release or threatened release. *Id.*

216. EPA, GUIDANCE MEMORANDUM ON USE AND ISSUANCE OF ADMINISTRATIVE ORDERS UNDER SECTION 106(A) OF CERCLA, *reprinted in* 1982 ALI-ABA COURSE OF STUDY, *supra* note 163, at 168, 171.

217. 42 U.S.C. § 9606(b) (Supp. IV 1986).

218. *Id.* § 9607(c)(3) (1982).

219. *CERCLA 1985*, *supra* note 203, at 10,396.

220. *Id.*

221. 42 U.S.C. § 9607(a)(4)(A) (Supp. IV 1986). Cost recovery actions by states com-

other person consistent with the national contingency plan;" and (3) "damages for injury to, destruction of, or loss of natural resources, including the reasonable costs" for damage assessment.[222]

Section 107 designates four categories of "persons" potentially liable under CERCLA for these costs. (1) current owners or operators of facilities,[223] (2) owners or operators of facilities at the time of hazardous substance disposal,[224] (3) anyone who arranged in any way for the disposal, treatment, or transport of hazardous substances (generators of the hazardous substances),[225] and (4) those who transport hazardous substances to a chosen site "from which there is a release, or a threatened release which causes the incurrence of response costs, of a hazardous substance."[226] The definition of "person" includes individuals, all forms of business enterprises, and governmental entities.[227]

monly occur. *CERCLA 1985*, *supra* note 203, at 10,399 (citing, for example, New York v. Shore Realty Corp., 759 F.2d 1032 (2d Cir. 1985)). Further, at least one court has held that a municipality qualifies as a state. *Id.* (citing Mayor of Boonton v. Drew Chem. Corp., 15 Envtl. L. Rep. (Envtl. L. Inst.) 20,962 (D.N.J. 1985)).

222. 42 U.S.C. § 9607(a)(4)(B)-(C) (Supp. IV 1986); *see also* 43 C.F.R. § 11 (1987) (providing procedures to assess and determine compensation for natural resource damages).

223. 42 U.S.C. § 9607(a)(1) (Supp. IV 1986). For the definition of "facility," see *supra* note 197. The definition of "facility" is intentionally expansive: "[T]he definition of 'facility' is necessarily a broad one. It explicitly defines facility as, among other things, any site or area where a hazardous substance has been deposited, stored, disposed of, or otherwise come to be located." 126 CONG. REC. 31,967 (1980) (remarks of Rep. Florio); *see also* United States v. Conservation Chem. Co., 619 F. Supp. 162, 185 (W.D. Mo. 1985) (stating that the term facility "includes every place where hazardous substances come to be located"); United States v. Ward, 618 F. Supp. 884, 895 (E.D.N.C. 1985) (holding that the term "facility" includes roadside ditches where contaminated oil was spread); New York v. General Elec. Co., 592 F. Supp. 291, 296 (N.D.N.Y. 1984) (finding a congressional intent to reach any site containing hazardous wastes and not merely a particular category of disposal sites); *cf.* United States v. Metate Asbestos Corp., 584 F. Supp. 1143, 1148 (D. Ariz. 1984) (requiring a plaintiff to show that a hazardous substance has been placed or is located in an area for the area to be considered a facility).

224. 42 U.S.C. § 9607(a)(2) (Supp. IV 1986). CERCLA gives "disposal" the broad meaning set forth in section 1004 of the Solid Waste Disposal Act, 42 U.S.C. § 6903(3) (1982): the "discharge, deposit, injection, dumping, spilling, leaking, or placing of any solid waste or hazardous waste into or on any land or water so that such . . . waste or any constituent thereof may enter the environment or be emitted into the air or discharged into any waters, including ground waters." 42 U.S.C. § 9601(29) (Supp. IV 1986) (cross-referencing 42 U.S.C. § 6903).

225. *Id.* § 9607(a)(3).

226. *Id.* § 9607(a)(4). CERCLA's definition of "release" encompasses any movement of a hazardous substance into the environment: "'release' means any spilling, leaking, pumping, pouring, emitting, emptying, discharging, injecting, escaping, leaching, dumping, or disposing *into the environment*." *Id.* § 9601(22) (emphasis added). The coordinate definition of "environment" is equally broad: "'[E]nvironment' means (A) the navigable waters, the waters of the contiguous zone, and the ocean waters . . . and (B) any other surface water, ground water, drinking water supply, land surface or subsurface strata, or ambient air within the United States or under the jurisdiction of the United States." *Id.* § 9601(8).

227. *Id.* § 9601(21). "'Person' is defined as an "individual, firm, corporation, association, partnership, consortium, joint venture, commercial entity, United States Government, State, municipality, commission, political subdivision of a State, or any interstate body." *Id.* "It is well established that a state or local government may be an owner or operator under CERCLA." *CERCLA 1985*, *supra* note 203, at 10,401; *see, e.g.*, Artesian Water Co. v. Government of New Castle County, 605 F. Supp. 1348, 1354 (D. Del. 1985) (holding that the county government falls within CERCLA's definition of "person"). Earlier drafts of CERCLA also included municipalities and governmental entities

Municipalities typically engage in one or more of four primary relationships when handling the solid waste generated within their borders. Municipalities may (1) collect and transport MSW to disposal sites or landfills; (2) collect MSW from residences, unload it at a transfer station, and contract with a third party to transport the MSW in large-load quantities to a disposal site or landfill; (3) contract with third parties for curbside collection and transport of MSW to a disposal site or landfill; or (4) provide no collection or transport services, requiring residents to self-haul MSW.

The waste handled by municipalities can be strictly residential, or a combination of residential and commercial collection. If MSW were characterized as a hazardous substance for purposes of CERCLA, the mix of refuse contributed to a landfill could have significant repercussions for municipalities. As discussed below, however, MSW may fall within a CERCLA exemption.[228]

A municipal or county governmental entity may own a landfill where MSW is disposed, or a municipal agency may operate an MSW landfill as either owner or assignee. The extent of a municipality's MSW role—generating, handling, or arranging for disposal of MSW on one hand, or actually owning or operating the disposal facilities on the other—determines potential municipal liability. Emerging federal law defines the boundaries of this liability.

V. Mending the Fabric: The Common Law of Liability

CERCLA was a quickly passed compromise bill that left many unanswered questions with respect to its liability scheme.[229] More than any other American pollution statute, CERCLA is shaped by the common law.[230] Congress left a key gap in the statutory

in their definitions of "person." *See, e.g.*, S. 1325, 96th Cong., 1st Sess. § 2, 125, CONG. REC. 14,389 (1979) (defining "person" to mean "an individual, firm, corporation, association, partnership, joint venture, or government entity"); S. 1480, 96th Cong., 1st Sess. § 2, 125, CONG. REC. 17,989 (1979) (defining "person" as defined in section 502 of the Clean Water Act). As amended, S. 1480 also included "municipality" in its definition of "person." S. 1480, 96th Cong. 2d Sess. § 101, 125, CONG. REC. 30,917 (1980) (as amended).

228. *See infra* notes 274-78 and accompanying text.

229. *See* Grad, *supra* note 150, at 1-2. For a discussion of the perhaps deliberate vagueness drafted into CERCLA to gain initial adoption, see Rogers, *The Generators' Dilemma in Superfund Cases*, 12 Envtl. L. Rep. (Envtl. L. Inst.) 15,049, 15,049-50 (1982).

230. This is due in part to the lack of detail in drafting. The heart of CERCLA, its liability provision, was deleted in the rush for enactment before the end of both the 96th Congress and the Carter presidency. United States v. A & F Materials Co., 578 F. Supp. 1249, 1253 (S.D. Ill. 1984). Congress looked to the common law developed under other statutes, and this reliance emerged as the federal district courts interpreted CERCLA. *See, e.g.*, Dedham Water Co. v. Cumberland Farms Dairy, Inc., 805 F.2d 1074, 1084 (1st Cir. 1986) (noting that Congress expanded the jurisdiction of the courts in response to a perceived gap in the CERCLA jurisdictional scheme). This is also due in part to the rushed compromise and last minute amendments that ensured the Act's passage:

> CERLCA was enacted on December 11, 1980 in the last days of the 96th

language describing the bases for imposing liability: whether a strict liability or negligence standard should apply, and whether liability is joint and several or individual. The government, as plaintiff, has argued that joint, several, and strict liability should attach through a de minimus or attenuated showing of causation.[231]

The government as plaintiff is compiling a successful record of CERCLA enforcement. Because CERCLA incorporates by reference section 311 of the Clean Water Act,[232] which holds violators strictly liable for damages,[233] courts have overwhelmingly held that strict liability applies to PRPs for cost recovery actions under CERCLA section 107, regardless of any negligence by owners, operators, transporters, or generators.[234] Although the final version of

Congress. The final version of the Act was conceived by an ad hoc committee of Senators who fashioned a last minute compromise that enabled the Act to pass. As a result, the statute was hastily and inadequately drafted. *A & F Materials Co.*, 578 F. Supp. at 1253. This rapid birth process left little authoritative legislative history, and a resultant statutory ambiguity to be interpreted by the courts.

231. *See, e.g.*, United States v. Bliss, 667 F. Supp. 1298, 1309-10 (E.D. Mo. 1987) (adopting the government's argument that traditional tort notions, such as proximate cause, do not apply, and that CERCLA requires only a relaxed standard of causation); United States v. Conservation Chem. Co., 619 F. Supp. 162, 236-37 (W.D. Mo. 1985) (upholding the government's assertion that it is unnecessary to "fingerprint" a particular generator's waste to establish liability; one need only show that the defendant's waste was disposed of at the site and that the substance that makes the waste hazardous is also present at the site); *cf.* City of New York v. Exxon Corp., 633 F. Supp. 609, 620 (S.D.N.Y. 1986) (requiring the city to show a causal connection between hazardous substances in defendant's waste and the response costs incurred at the city's landfills).

232. 33 U.S.C.A. § 1321 (West 1986 & Supp. 1988); 42 U.S.C. § 9601(32) (Supp. IV 1986) (providing that liability under CERCLA shall be construed as the standard of liability under title 33, section 1321).

233. *See* 33 U.S.C.A. § 1321 (West 1986 & Supp. 1988). As one senator explained:

> Unless otherwise provided in this act, the standard of liability is intended to be the same as that provided in section 311 of the Federal Water Pollution Control Act (33 U.S.C. 1321). I understand this to be a standard of strict liability.
>
> It is intended that issues of liability not resolved by this act, if any, shall be governed by traditional and evolving principles of common law. An example is joint and several liability. Any reference to these terms has been deleted, and the liability of joint tort feasors will be determined under common or previous statutory law.

126 CONG. REC. 30,932 (1980) (remarks of Sen. Randolph); *see also id.* at 31,965 (statement of Rep. Florio) ("With respect to strict liability, this bill contains no significant change from that in our earlier bill. . . . Thus, the absence of negligence is not a defense to liability.").

234. *See* Bulk Distrib. Centers, Inc. v. Monsanto Co., 589 F. Supp. 1437, 1443 n.15 (S.D. Fla. 1984); United States v. Conservation Chem. Co., 589 F. Supp. 59, 62 (W.D. Mo. 1984); United States v. Northeastern Pharmaceutical & Chem. Co. (*NEPACCO I*), 579 F. Supp. 823, 843-44, 847 (W.D. Mo. 1984), *aff'd in relevant part, rev'd in part*, 810 F.2d 726 (8th Cir. 1986), *cert. denied*, 108 S. Ct. 146 (1987); United States v. Argent Corp., 21 Env't Rep. Cas. (BNA) 1354, 14 Envtl L. Rep. (Envtl. L. Inst.) 20,616 (D.N.M. 1984); United States v. South Carolina Recycling & Disposal, Inc. (*SCRDI*), 653 F. Supp. 984, 991 n.2 (D.S.C. 1984); United States v Ottati & Goss, Inc., 630 F. Supp 1361, 1392-93 (D.N.H. 1985); United States v. Price, 577 F. Supp. 1103, 1113-14 (D.N.J 1983); United States v. Chem-Dyne Corp., 572 F. Supp. 802, 804-07 (S.D. Ohio 1983); Philadelphia v. Stepan Chem. Co., 544 F. Supp. 1135, 1140 n.4 (E.D. Pa. 1982); *cf* United States v. Cauffman, 21 Env't Rep. Cas. (BNA) 467, 15 Envtl. L. Rep. (Envtl L. Inst.) 2016 (C.D. Cal. 1984) (stating that the government need not prove proximate cause); United States v. Wade, 546 F. Supp. 785, 793-94, (E.D. Pa. 1982) (finding a non-negligent off-site generator not liable), *appeal dismissed*, 713 F.2d 49 (3d Cir. 1983).

CERCLA deleted all reference to joint and several liability,[235] courts have determined that PRP liability is joint and several if there is no basis for dividing the responsibility for the injury.[236] Plaintiffs are therefore not required to link their response costs with particular releases by particular defendants, because to require such "fingerprinting" of wastes would eviscerate CERCLA's liability provisions and would be inconsistent with Congress's intent.[237]

Moreover, courts have not required a showing of proximate cause to impose liability on the generators of wastes sent to Superfund sites,[238] despite legislative history suggesting that proof of causation is required before liability may be imposed.[239] Courts have held that sufficient causation exists if the generators' wastes are on site, and a threatened release of *any* hazardous substance requires some EPA response action.[240] Thus, once plaintiffs show that a hazardous substance was released from a "facility," and that they incurred "response costs" to address a hazardous substance of the type released, plaintiffs have established the requisite causation. Moreover, for purposes of CERCLA's cleanup requirements, the EPA can compel remediation on a showing of potential endangerment although no

235. *See* 126 CONG. REC. 31,965 (1980).

236. *See* Colorado v. ASARCO, Inc., 608 F. Supp. 1484, 1486 (D. Colo., 1985); United States v. Ward, 618 F. Supp. 884, 893 (E.D.N.C. 1985); United States v. Stringfellow, 20 Env't Rep. Cas. (BNA) 1905, 1909, 14 Envtl. L. Rep. (Env't L. Inst.) 20,381, 20,385 (C.D. Cal. 1984); *Bulk Distrib. Centers, Inc.*, 589 F. Supp. at 1443; *NEPACCO I*, 579 F. Supp. at 845; *Conservation Chem. Co.*, 589 F. Supp at 63; *SCRDI*, 653 F. Supp. at 994; *Chem-Dyne Corp.*, 572 F. Supp. at 810; United States v. Wade, 577 F. Supp. 1326, 1338-39 (E.D. Pa. 1983). *But see* New York v. Shore Realty Corp., 759 F.2d 1032, 1042 (2d Cir. 1985) (stating that joint and several liability is not absolute under certain circumstances).

237. *See* Violet v. Picillo, 648 F. Supp. 1283, 1292 (D.R.I. 1986) (stating that to establish waste and the harm caused by the release at a particular site, "CERCLA only requires that the plaintiff prove . . . that the defendant deposited his hazardous waste at the site and that the hazardous substances contained in the defendant's waste are also found at the site"); *Wade*, 577 F. Supp. at 1332-33 (to same effect); *see also Shore Realty*, 759 F.2d at 1044-45 (declining to find a causation requirement in CERCLA § 107(a)).

238. *SCRDI*, 653 F. Supp. at 992; *Wade*, 577 F. Supp. at 1333-34; *see* 126 CONG. REC. 26,786 (1980) (statement of Rep. Stockman).

239. The House Report states:

> The Committee intends that the usual common law principles of causation, including those of proximate causation, should govern the determination of whether a defendant "caused or contributed" to a release or threatened release. . . . The Committee intends that for liability to attach under this section, the plaintiff must demonstrate a causal or contributory nexus between the acts of the defendant and the conditions which necessitated response action under section 3041.

H.R. REP. NO. 1016, 96th Cong., 2d Sess., pt. 1, 33-34, *reprinted in* 1980 U.S. CODE CONG. & ADMIN. NEWS 6119, 6136-37.

240. *See* United States v. Ottati & Goss, Inc., 630 F. Supp. 1361, 1393-94 (D.N.H 1985); *Wade*, 577 F. Supp. at 1332-34; *see also* United States v. Hardage, 18 Env't Rep. Cas. (BNA) 1685, 1686, 13 Envtl. L. Rep. (Envtl. L. Inst.) 20,188, 20,189 (W.D. Okla. 1982) (finding strict liability for persons contributing to the handling, transportation or disposal of hazardous wastes that substantially endanger health or the environment).

actual harm is present.[241]

Any quantity, level, or concentration of a hazardous substance as defined by CERCLA, is sufficient to trigger liability for any class of PRP generators.[242] Indeed, one court has held that there is no requirement to show that a defendant's waste remains on site to hold the defendant liable for remediation.[243]

Recently, courts have also held that a showing of proximate cause is not required before liability may be imposed on current or former owners or operators of disposal sites.[244] Under section 107 lessors of Superfund sites during the time of disposal may also be held liable for cleanup costs.[245] A showing of proximate cause is required, however, before imposing liability on transporters of hazardous substances, whom both the statute[246] and a few cases[247] link to cleanup costs only if they were responsible for selecting the disposal site. In one instance transporter liability was found to attach to a party who cleaned up one contaminated site by transporting wastes to a second site which subsequently became contaminated.[248]

CERCLA authorizes imposing liability on those having no ongoing relationship with a contaminated site, and courts have generally held that this retroactive liability does not violate the requirements

241. *See, e.g.*, United States v. Mirabile, 15 Envtl. L. Rep. (Envtl. L. Inst.) 20,992, 20,993 (E.D. Pa. Sept. 4, 1985) (stating that a threatened release is sufficient to compel remediation); *see also* cases cited *supra* note 240.

242. Eagle-Picher Indus. v. EPA, 759 F.2d 922, 927 (D.C. Cir. 1985); United States v. Conservation Chem. Co., 619 F. Supp. 162, 238 (W.D. Mo. 1985); United States v. Carolawn Co., 21 Env't Rep. Cas. (BNA) 2124, 2126 (D.S.C. 1984). *Contra* United States v. Ottati & Goss, Inc., 8 Chemical & Radiation Waste Litigation Rep. 674, 677 (D.N.H. July 25, 1984) (finding that trace amounts of heavy metals below EPA threshold levels for hazardous wastes are not "hazardous substances" for CERCLA purposes).

243. *See* United States v. South Carolina Recycling & Disposal, Inc. (*SCRDI*), 653 F. Supp. 984, 992 (D.S.C. 1984).

244. *See* New York v. Shore Realty Corp., 759 F.2d 1032, 1043-44 (2d Cir. 1985); United States v. Cauffman, 21 Env't Rep. Cas. (BNA) 2167, 2168 (C.D. Cal. 1984); *see also* United States v. Price, 523 F. Supp. 1055, 1073-74 (D.N.J. 1981) (holding subsequent landowners liable merely by virtue of "studied indifference" to hazardous condition), *aff'd*, 688 F.2d 204 (1st Cir. 1982).

Section 107 authorizes imposing liability on former owners and operators of disposal sites. *See* 42 U.S.C. § 9607(a) (Supp. IV 1986) (as modified by SARA § 101(f), 42 U.S.C. § 9601(35) (Supp. IV 1986)). However, former owners and operators during a period when no hazardous substances were disposed may logically avail themselves of third-party defenses. *See infra* note 257.

245. United States v. Northeastern Pharmaceutical & Chem.Co. (*NEPACCO I*), 579 F. Supp. 823, 840-43 (W.D. Mo. 1984), *aff'd in part, rev'd in part*, 810 F.2d 726 (8th Cir. 1986), *cert. denied*, 108 S. Ct. 146 (1987); *SCRDI*, 653 F. Supp. at 1003; United States v. Argent, 21 Env't Rep. Cas. (BNA) 1354, 1356, 14 Envtl. L. Rep. (Envtl. L. Inst.) 20,616, 20,617 (D.N.M. 1984).

246. 42 U.S.C. § 9607(a)(4) (Supp. IV 1986).

247. United States v. Ottati & Goss, Inc., 630 F. Supp. 1361, 1402-05 (D.N.H. 1985); *SCRDI*, 653 F. Supp. at 1005; *see* United States v. Conservation Chem. Co., 619 F. Supp. 162, 191 (W.D. Mo. 1985); *NEPACCO I*, 579 F. Supp. at 847.

248. United States v. South Carolina Recycling & Disposal, Inc. (*SCRDI*), 653 F. Supp. 984, 1005-06 (D.S.C. 1984). This continuing liability is limited by the recent Superfund amendments. Contractors who undertake response actions in a non-negligent manner are granted immunity from federal (though not state) CERCLA liability. The EPA can also grant limited immunity to contractors who are not able to obtain liability insurance on reasonable terms. *See* SARA § 119, 42 U.S.C. § 9619(a)(1), (c)(1)-(14) (Supp. IV 1986).

of due process.[249] Although a municipality may have ceased to generate or transport MSW to a Superfund site prior to CERCLA's enactment, this alone will not relieve the municipality from liability. Former generators of any hazardous substance remain liable.[250] Even if the wastes, once safely disposed of, are subsequently and perhaps illegally removed to a second site where contamination occurs, the original generator remains liable.[251]

Former transporters of hazardous substances who selected the disposal site also remain liable.[252] Former owners who owned the site at any time when hazardous substances were disposed of remain liable as well.[253] However, former owners who did not own the site during a period of hazardous waste disposal, who did not know that any hazardous substance was disposed at the site, and who exercised due care, are not liable under section 107.[254] The sale of a site, which subsequently poses a threat, leaves liable both the former owner who owned the site during the period of hazardous waste disposal, and the current owners purchasing with actual or constructive knowledge of likely contaminants, whether or not current disposal occurs.[255]

Former owners and operators of abandoned hazardous waste dis-

249. *SCRDI*, 653 F. Supp. at 997 (citing Usery v. Turner Elkhorn, 428 U.S. 1 (1976)); *Ottati & Goss, Inc.*, 630 F. Supp. at 1398; *Conservation Chem. Co.*, 619 F. Supp. at 221-22; United States v. 250. Missouri v. Independent Petrochemical Corp., 610 F. Supp. 4, 5 (E.D. Mo. 1985); Jones v. Inmont Corp., 584 F. Supp. 1425, 1428-29 (S.D. Ohio 1984); United States v. A & F Materials, 578 F. Supp. 1249, 1257 (S.D. Ill. 1984); United States v. Northeastern Pharmaceutical & Chem. Co. (*NEPACCO I*), 579 F. Supp. 823, 839, 847; United States v. Stringfellow, 20 Env't Rep. Cas. (BNA) 1912, 1915, 14 Envtl. L. Rep. (Envtl. L. Inst.) 20,388, 20,389 (C.D. Cal. 1984); United States v. Wade, 546 F. Supp. 785, 793 (E.D. Pa. 1982).

251. *Independent Petrochemical Corp.*, 610 F. Supp. at 5; *see also* Violet v. Picillo, 648 F. Supp. 1283, 1285 (D.R.I. 1986) (finding generator liable for the ultimate disposal of waste diverted by the transporter from the site selected by the generator to a second site); United States v. Conservation Chem. Co., 619 F. Supp. 162, 234 (W.D. Mo. 1985) (stating that generators are liable for waste trans-shipped to unknown second sites). In the Cannons superfund litigation the EPA has alleged that generators are liable for all costs where a disposal site owner illegally moved waste to two other locations and thereby caused contamination. *See infra* note 272 and accompanying text.

252. *NEPACCO I*, 579 F. Supp. at 846-47; *Georgeoff*, 562 F. Supp at 1309-14.

253. United States v. Carolawn Co., 14 Envtl. L.Rep. (Envtl. L. Inst.) 20,699, 20,700 (D.S.C. 1984); United States v. Reilly Tar & Chem. Co., 546 F. Supp. 1100, 1113 (D. Minn. 1982).

254. *See* 42 U.S.C. § 9607(b)(3) (1982); SARA § 101(35), 42 U.S.C. § 9601(35) (Supp. IV 1986).

255. The 1986 Superfund Amendments created an "innocent owner" defense to CERCLA liability for defendants who acquired the disposal site after the disposal or placement of the hazardous material, provided: (1) the defendant did not know or have reason to know of the hazardous material at the time the property was acquired; (2) the defendant is a governmental entity and acquired the property by escheat, involuntary

posal sites also remain potentially liable.[256] Unless PRPs can avail themselves of one of the extremely limited defenses provided by statute,[257] or equitable defenses developed at common law such as laches,[258] estoppel,[259] unclean hands,[260] and others,[261] liability is

transfer, eminent domain, or the like, or (3) the defendant inherited the property. SARA § 101(l), 42 U.S.C. § 9601(35) (Supp. IV 1986).

Under CERCLA the corporate veil can also be pierced. Corporate officers of a generator company, if they personally arranged for disposal of waste or had direct supervision, are liable under sections 106 and 107. *See, e.g.*, United States v. Northeastern Pharmaceutical & Chem. Co. (*NEPACCO II*), 810 F.2d 726, 744 (8th Cir. 1986) (holding that an individual who participated in conduct that violated CERCLA may be held personally liable), *cert. denied*, 108 S. Ct. 146 (1987); United States v. Conservation Chem. Co., 619 F. Supp. 162, 190 (W.D. Mo. 1985) (holding that corporate officials who actively participate in the management of a disposal facility may be held personally liable); *Carolawn Co.*, 14 Envtl. L. Rep. (Envtl. L. Inst.) at 20,700 (stating that ownership, control, authority, or participation in management results in individual liability); Escude Cruz v. Ortho Pharmaceutical Corp., 619 F.2d 902, 907 (1st Cir. 1980) (stating that personal liability may be found when the corporate officer was the guiding spirit behind the wrongful conduct). Shareholders also can be held liable under section 107(a) in certain circumstances. New York v. Shore Realty Corp., 759 F.2d 1032, 1039, 1052 (2d Cir. 1985) (holding stockholder of corporation that purchased the dump site liable when such stockholder had been warned about potential problems); United States v. Mottolo, 605 F. Supp. 898, 913-14 (D.N.H. 1985) (imposing individual liability on president/shareholder who participated in disposal activities); United States v. Northeastern Pharmaceutical & Chem. Co. (*NEPACCO I*), 579 F. Supp. 823, 848-49 (W.D. Mo. 1984) (imposing liability when stock ownership plus active management were present), *aff'd in part, rev'd in part*, 810 F.2d 726 (8th Cir. 1986), *cert. denied*, 108 S. Ct. 146 (1987).

256. 42 U.S.C. § 9607(a)(2) (Supp. IV 1986); *see also* SARA § 101, 42 U.S.C. § 9601(35)(c) (Supp. IV 1986) (providing that the amended section on defenses for new owners shall not diminish the liability of former owners or operators); *Shore Realty Corp.*, 759 F.2d at 1044 (noting that under CERCLA, former owners or operators are liable "only if they owned or operated the facility 'at the time of disposal of any hazardous substance'" (quoting CERCLA § 107(a))).

257. *See* 42 U.S.C. § 9607(b) (1982). These defenses are available when releases of hazardous substances are caused by (1) acts of war, (2) acts of God, or (3) acts of unrelated third parties with whom a PRP has no direct or indirect contractual link, where the PRP exercises due care with respect to any hazardous substances. *See id.* The recent Superfund Amendments clarify the conditions of a contractual relationship pertaining to this third defense. *See* SARA, §§ 101(35), 119, 42 U.S.C. §§ 9601(35), 9619 (Supp. IV 1986). Analogous precedent exists under similar statutory provisions of section 311 of the Clean Water Act, 33 U.S.C.A. § 1321(i)(1) (West 1986 & Supp. 1988). *See* Minneapolis Park & Recreation Bd. v. United States, 231 Ct. Cl. 738, 739 (1982); Travelers Indem. Co. v. United States, 230 Ct. Cl. 867, 868-69 (1982).

258. The equitable doctrine of laches may be applied if a plaintiff is responsible for undue delay in asserting his legal rights, resulting in prejudice to the defendant. *E.g.*, Cobb v. Prokop, 557 F. Supp. 391, 397 (D. Mass. 1983). Section 107(b) does not prohibit, inter alia, defenses such as laches. *Conservation Chem. Co.*, 619 F. Supp. at 206 (citing Mardan Corp. v. C.G.C. Music, Ltd., 600 F. Supp. 1049, 1056 n.9 (D. Ariz. 1984), *aff'd*, 804 F.2d 1454 (9th Cir. 1986)). A "'determination of whether the doctrine of laches should bar a claim requires consideration of all the circumstances of a particular case.'" *Id.* (quoting United States v. Reilly Tar & Chem. Corp., No. 4-80-469, slip. op. at 5 (D. Minn. June 14, 1984)). Laches is also a defense to a section 107(a) suit, which is essentially an equitable claim seeking reimbursement for monies spent. *See* United States v. Mottolo, 605 F. Supp. 898, 909 (D.N.H. 1985) (dictum).

The United States Supreme Court has held that the defense of laches is not available against the government, even in equitable actions, if the government is enforcing a public right or protecting a public interest. Utah Power & Light Co. v. United States, 243 U.S. 389, 409 (1917). Lower courts have therefore recognized that this defense may not be asserted against the government in a CERCLA action. *See Mottolo*, 605 F. Supp. at 909; *see also* United States v. Dickerson, 640 F. Supp. 448, 451 (D. Md. 1986) (granting government's motion to strike defendants' affirmative defense of laches in a CERCLA suit).

Given the strong public interest in government prosecution of CERCLA violations, it

joint, several, and strict.[262] When the dump site owner or operator is a municipality, county, or state agency, CERCLA treats the entity as a private person.[263]

seems unlikely that laches could be asserted successfully by a defendant PRP in a section 106 or section 107 action brought by the government. However, this does not rule out its use as a defense by a defendant PRP against a private party bringing a section 107 cost recovery action, or in contribution actions brought by other PRPs.

259. The basic standard for a valid estoppel is articulated in Bergeron v. Mansour, 152 F.2d 27 (1st Cir. 1945): "A person is estopped from denying the consequences of his conduct where that conduct has been such as to induce another to change his position in good faith or such that a reasonable man would rely upon the representations made." *Id.* at 30. Reliance is reasonable if the party claiming the estoppel neither knew nor should have known that its adversary's conduct was misleading. Heckler v. Community Health Servs., 467 U.S. 51, 59 (1984).

Although the equitable defense of estoppel has not been reviewed by the courts in CERCLA cases, the district court in *Conservation Chem. Co.* stated in dictum that estoppel would be an appropriate defense in section 107 actions. *Conservation Chem. Co.*, 619 F. Supp. at 206.

The Supreme Court has left open the question of whether equitable estoppel may be used against the government. *Heckler*, 467 U.S. at 60. Traditional equitable estoppel "does not apply fully in cases of estoppel against the Government. For the Government to be estopped, it is necessary not only that the party relied on the Government's conduct—the basis of the traditional doctrine—but also that the Government have engaged in "'affirmative misconduct.'" Akbarin v. INS, 669 F.2d 839, 842 (1st Cir. 1982).

It is not clear, from decisions to date, what constitutes "affirmative misconduct" for purposes of an estoppel. Neither neglect of duty, nor a failure to be of assistance, nor a failure by a government agency to respond to inquiries, constitutes sufficient "affirmative misconduct" by the government to warrant an estoppel. Simon v. Califano, 595 F.2d 121, 125 (9th Cir. 1979) (neglect of duty); Lavin v. Marsh, 644 F.2d 1378, 1384 (9th Cir. 1981) (failure to assist); Precious Metals Assocs., Inc., v. Commodity Futures Trading Comm'n, 620 F.2d 900, 909 (1st Cir. 1980) (failure to respond). Moreover, even when affirmative misconduct and reasonable reliance occur, it is not clear that the government should be estopped. The Supreme Court has indicated that if estoppel would threaten a public interest, courts should be reluctant to apply this defense. *Heckler*, 467 U.S. at 60-61; *see Akbarin*, 669 F.2d at 842.

260. *See* Kalik v. Allis-Chalmers Corp., 658 F. Supp. 631, 637-38 (W.D. Pa. 1987); Mardan Corp. v. C.G.C. Music Ltd., 600 F. Supp. 1049, 1057-58 (D. Ariz. 1984). Courts have recognized that the defense of unclean hands may be asserted against the government, but have suggested that the doctrine is unlikely to bar successfully the government's claims under CERCLA. *See Conservation Chem. Co.*, 619 F. Supp. at 206; *Mardan*, 600 F. Supp. at 1057.

261. As a defense, 42 U.S.C. § 9612(d) (Supp. IV 1986) provides a statute of limitations allowing three years from discovery for the initiation of damage actions and six years after completion of response action for cost recovery actions. As another defense, most courts agree that Congress has not authorized nationwide service of process for CERCLA actions. *See, e.g., In re* Acushnet River & New Bedford Harbor Proceedings Re Alleged PCB Pollution, 675 F. Supp. 22, 29 & n.7 (D. Mass. 1987); Welmer v. Syntex Agribusiness, Inc., 616 F. Supp. 27, 28 (E.D. Mo. 1985); Violet v. Picillo, 613 F. Supp. 1563, 1573 (D.R.I. 1985). Only one court has found that CERCLA authorizes nationwide service of process for abatement actions under section 106. *See* United States v. Bliss, 108 F.R.D. 127, 134-35 (E.D. Mo. 1985).

Finally, it may be possible to interpose the defense of unjust enrichment to prevent a landowner from obtaining contribution or indemnification. *Cf.* Gould v. American Hawäiian S.S. Co., 387 F. Supp. 163, 171 (D. Del. 1974) (denying contribution in a federal securities action on unjust enrichment grounds), *vacated on other grounds*, 535 F.2d 761 (3d Cir. 1976).

262. *See supra* text accompanying notes 234-36.

263. 42 U.S.C. § 9601(21) (Supp. IV 1986); *see, e.g.*, Artesian Water Co. v. Govern-

A municipality may also find itself in the unenviable position of currently or formerly owning a sanitary landfill where hazardous industrial or commercial waste was illegally dumped. Under CERCLA precedent, "by virtue of their studied indifference to the hazardous condition," an otherwise innocent owner remains subject to CERCLA liability.[264] If a governmental entity is a co-owner or co-operator of a waste disposal facility and not directly prosecuted as a PRP, the entity may still be liable for indemnification or contribution costs to the co-owners.[265] Municipal owners and operators of landfills are jointly, severally, and strictly liable for all cleanup costs, including those incurred prior to CERCLA's enactment.[266]

Municipalities have a dual role under CERCLA. First, by virtue of their inclusion in the definitional section, municipalities as defendants can be held liable for threats posed by hazardous substances for which they are responsible as generators, transporters, owners, or operators.[267] Second, municipalities as plaintiffs can also recover the costs they incurred in their cleanup efforts. CERCLA section 107 authorizes recovery by a state government for natural resources damages, and courts have upheld a municipality's possible status as both plaintiff and defendant.[268]

Obviously, municipalities and municipal officials in their official capacities do not "generate" or create MSW or its potentially hazardous constituents. However, municipalities do conduct, sanction, or arrange for the collection and disposal of MSW. The degree of municipal responsibility for waste disposal ranges from a limited role in which the municipality contracts away its disposal responsi-

ment of New Castle County, 605 F. Supp. 1348, 1355 (D. Del. 1985) (finding that Congress did not intend to differentiate between governmental and nongovernmental entities for purposes of CERCLA liability).

264. United States v. Price, 523 F. Supp. 1055, 1073 (D.N.J. 1981), *aff'd*, 688 F.2d 204 (3d Cir. 1982); *see also* City of Philadelphia v. Stepan Chem. Co., 544 F. Supp. 1135, 1143 (E.D. Pa. 1982) (dictum) (hypothesizing that a municipality might be liable to federal or state governments for response costs even if the city did not voluntarily permit hazardous waste disposal on its property).

265. Velsicol Chem. Corp. v. Reilly Tar Chem. Corp., 21 Env't Rep. Cas. (BNA) 2,118, 2,121, 15 Envtl. L. Rep. (Envtl. L. Inst.) 20,103, 20,105-06 (E.D. Tenn. 1984). Cost recovery actions can be maintained by any PRP who incurs cleanup costs against other non-contributing PRPs. *See* United States v. New Castle County, 642 F. Supp. 1270, 1276 (D. Del. 1986); United States v. Medley, 17 Envtl. L. Rep. (Envtl. L. Inst.) 20,297, 20,298 (D.S.C. 1986); Pinole Point Properties v. Bethlehem Steel Corp., 596 F. Supp. 283, 290-91 (N.D. Cal. 1984).

266. United States v. Shell Oil Co., 605 F. Supp. 1064, 1079 (D. Colo. 1985); Mayor of Boonton v. Drew Chem. Corp., 621 F. Supp. 663, 668 (D.N.J. 1985); *cf.* United States v. Northeastern Pharmaceutical & Chem. Co. (*NEPACCO II*), 810 F.2d 726, 741 (8th Cir. 1986) (stating that off-site generators and transporters of hazardous waste are strictly liable for cleanup costs, including those resulting from activities prior to CERCLA's enactment), *cert. denied*, 108 S. Ct. 146 (1987).

267. *See* 42 U.S.C. § 9601(21) (Supp. IV 1986) (including municipality in the definition of a "person" under CERCLA). *But cf. id.* § 9601(20)(D) (providing state or local government limitation to definition of "owner or operator" if ownership was acquired involuntarily through bankruptcy, tax delinquency, abandonment, or other sovereign functions).

268. *See Drew Chem. Co.*, 621 F. Supp. at 667 (construing the definition of "state" in CERCLA to include municipalities for purposes of both liability and standing to sue); *Stepan Chem. Co.*, 544 F. Supp. at 1141-43 (indicating that municipality can be either plaintiff or defendant).

bility to private companies in some communities, to a total pail-to-dump control in others.[269] In no event is either municipal solid waste or its hazardous components formally "owned" by the municipality. However, these distinctions do not necessarily absolve a municipality from liability for hazardous constituents found in MSW for which the municipality arranges disposal. Under CERCLA section 107 possession or arranging for the treatment or disposal of hazardous substances is a sufficient nexus to establish liability as a "generator" of these substances.[270]

CERCLA is ambiguous regarding whether, in order to be characterized a "generator" of hazardous waste, the municipality must select the disposal site for MSW containing hazardous constituents. Some cases suggest that generator liability attaches only if the PRP arranged to dispose of the hazardous substances at a particular site that is later found to be contaminated.[271] Other cases, however, suggest that if the PRP arranged to send the waste somewhere for disposal, liability attaches regardless of where the hazardous substances are ultimately disposed of, provided the threatened release of the substances poses an actionable public health threat.[272] Thus, one court recently held that generators remain strictly liable for the adverse impacts of the wastes they created; defenses such as lack of negligence or exercise of due care against transporter or site owner, or operator diversion of the wastes, may not be used to avoid liability, although such defenses may be relevant to apportionment of liability.[273]

One possible defense to liability exists if MSW is recycled as an input into a refuse-derived-fuel or waste-to-energy facility. Such facilities escape RCRA regulation.[274] In *United States v. A & F Materials*

269. *See supra* text following note 227.

270. 42 U.S.C. § 9607(a)(3) (Supp. IV 1986).

271. *See supra* notes 246-48 and accompanying text.

272. The EPA has negotiated with more than 380 PRPs for contributions to cleanup costs at four Cannons Engineering Corporation Superfund sites under this theory. In the Cannons matter, the owner of the disposal facility, licensed by the state of Massachusetts, illegally dumped excess waste at two unowned out-of-state locations. The EPA entered a settlement with all but two dozen PRPs to undertake cleanup at the original and the unauthorized contaminated sites. *See* 19 Env't Rep. (BNA) 615 (Aug. 12, 1988). *See generally* Ferrey, *supra* note 132 (suggesting that all PRPs remain liable for costs of cleanup and damages).

273. United States v. Conservation Chem. Co., 619 F. Supp. 162, 204 (W.D. Mo. 1985).

274. RCRA provides that a resource recovery facility will not be subject to standard RCRA regulation if it burns only household waste plus other non-hazardous waste and does not accept hazardous wastes as defined in RCRA. 42 U.S.C. § 6921(i) (Supp. IV 1986).

Unsuccessful legislation was introduced in 1987 and 1988 by Representative Florio that would require the EPA to regulate MSW incineration under RCRA. *See* H.R. 4902, 100th Cong., 2d Sess. (1988); H.R. 2787, 100th Cong., 1st Sess. (1987); H.R. 2517, 100th Cong., 1st Sess. (1987); H.R. 2516, 100th Cong., 1st Sess. (1987). The EPA pro-

Co.,[275] the district court suggested that, although conventional wastes can be sold for reprocessing, generator liability remains with the seller if the seller knows that some hazardous wastes will require disposal after reprocessing.[276] Although no court has yet addressed the issue of liability for reprocessed or recycled MSW, the court's reasoning in *A & F Materials Co.* suggests that cities and towns that incinerate their MSW, knowing that hazardous substances will remain in the bottom ash, may still be held liable if the hazardous residue is not disposed of properly.

By contrast, communities that convert their MSW to energy using state-of-the-art gasification technologies[277] apparently escape generator liability under the court's reasoning in *A & F Materials Co.*, because a municipality is excused from generator liability if the hazardous substance is sold as a product.[278] The substance must, therefore, be considered a product rather than a waste for the governmental entity to escape liability under the *A & F Materials Co.* rationale.

VI. The Shield of the Sovereign

States and municipalities are created pursuant to sovereign powers. This benign birth shields states and muncipalities, in certain circumstances, from the slings and arrows of outrageous legal fortune. In assessing the extent of CERCLA liability, it is therefore critical that courts determine whether Congress has abrogated state sovereign immunity, whether that immunity extends to municipalities, and whether there are independent bases in state law for municipal immunity.

A. State Sovereign Immunity

CERCLA on its face appears to include in its liability scheme all governmental entities as "persons" and imposes liability on any generator of a hazardous substance, or on the owner or operator of a facility from which there has been a release or threatened release of a hazardous substance that causes the incurrence of response

posed requiring pollution control devices on new and (eventually) on existing municipal incinerators. *See* 52 Fed. Reg. 25,399 (1987) (to be codified at 40 C.F.R. pt. 60); Wall St. J., July 2, 1987, at 30.

275. 582 F. Supp. 842 (S.D. Ill. 1984).

276. *Id.* at 845. The court distinguished the situation where a party sells the hazardous substance for use in a manufactured product without arranging for the disposal of the hazardous substance or end-product. In this instance, there is no disposal and therefore no liability. *See id.*

277. For example, Power Recovery Systems, Inc., in Cambridge, Massachusetts, developed advanced gasification technologies to use refuse-derived-fuel to drive internal combustion engines or boilers, with virtually no pollution emitted and no hazardous quantities in the residue.

278. United States v. Westinghouse Elec. Corp., 22 Env't Rep. Cas. (BNA) 1,231, 1,233, 14 Envtl. L. Rep. (Envtl. L. Inst.) 20,483, 20,484 (S.D. Ind. 1983) (stating that a manufacturer of a hazardous *product* that eventually turns up in waste is not liable as a generator); *cf.* New York v. General Elec. Co., 592 F. Supp. 291, 297 (N.D.N.Y. 1984) (stating that sale of *waste* products does not remove liability from generator).

costs.[279] Such sweeping liability is consistent with the fundamental objective of CERCLA, which courts have interpreted as the abatement of hazardous substance threats "by placing the ultimate financial burden upon those responsible for the danger."[280] CERCLA appears to include governmental entities as potentially responsible parties unless there is a sovereign immunity bar.

Section 107(g) of CERCLA expressly waives *federal* sovereign immunity for cleanup actions brought against federal agencies.[281] However, CERCLA and its legislative history are silent with respect to state sovereign immunity otherwise granted by the Eleventh Amendment.[282]

Read literally, the Eleventh Amendment appears to protect a state only from suits brought in federal court by individuals who are not citizens of that state.[283] Through a long history of judicial interpretation, however, the states enjoy more extensive immunity from suit than the literal interpretation of the Eleventh Amendment would suggest.[284] The Eleventh Amendment is interpreted as a plenary

279. *See supra* text accompanying notes 223-27.

280. City of Philadelphia v. Stepan Chem. Co., 544 F. Supp. 1135, 1142-43 (E.D. Pa. 1982). For further discussion of potential liability under CERCLA, see FMC Corp. v. Northern Pump Co., 668 F. Supp. 1285, 1289 (D. Minn. 1987); Artesian Water Co. v. Government of New Castle County, 659 F. Supp. 1269, 1280-81 (D. Del. 1987); Idaho v. Bunker Hill Co., 635 F. Supp. 665, 671 (D. Idaho 1986); and United States v. Conservation Chem. Co., 628 F. Supp. 391, 417-20 (W.D. Mo. 1985).

281. CERCLA § 107(g), 42 U.S.C. § 9620(a)(1) (Supp. IV 1986), states in pertinent part:

> Each department, agency, and instrumentality of the United States (including the executive, legislative, and judicial branches of the government) shall be subject to, and comply with, this chapter in the same manner and to the same extent, both procedurally and substantively, as any nongovernmental entity, including liability under section 9607 of this title.

Id.

282. U.S. CONST. amend. XI. The Eleventh Amendment states: "The Judicial power of the United States shall not be construed to extend to any suit in law or equity, commenced or prosecuted against one of the United States by Citizens of another State, or by Citizens or Subjects of any Foreign State."

283. Fletcher, *A Historical Interpretation of the Eleventh Amendment: A Narrow Construction of an Affirmative Grant of Jurisdiction Rather than a Prohibition Against Jurisdiction*, 35 STAN. L. REV 1033, 1060 (1983).

284. *See, e.g.*, Pennhurst State School & Hosp. v. Halderman, 465 U.S. 89 (1984) (holding that a federal court cannot award injunctive relief against state officers on the basis of state law); Edelman v. Jordan, 415 U.S. 651 (1974) (holding that the Eleventh Amendment bars retroactive payment from public funds in the state treasury when the state has not consented to suit); Hans v. Louisiana, 134 U.S. 1, 20-21 (1890) (stating that the state's consent to suit is required unless the suit involves a state contract conferring property or rights). Some scholars argue that the Eleventh Amendment was never intended to reach cases involving federal question jurisdiction, but rather only diversity jurisdiction. *See, e.g.*, Amar, *Of Sovereignty and Federalism*, 96 YALE L.J. 1425, 1474-75 (1987) (arguing that the Eleventh Amendment was adopted to eliminate two categories of diversity jurisdiction, i.e., "those involving noncitizen or foreign plaintiffs and state defendants," but was not designed to bar jurisdiction in federal question and admiralty cases). The present CERCLA issues devolve from federal question jurisdiction and a construction of the Commerce Clause, U.S. CONST. art. I, § 8, cl. 3. If correct, this

grant of sovereign immunity to the states as parties to private actions brought in federal court.[285] The doctrine of sovereign immunity therefore precludes a litigant from asserting an otherwise meritorious claim against a party with sovereign attributes unless the sovereign consents to be sued.[286]

The Supreme Court requires an explicit showing of congressional intent before finding a statutory abrogation of state sovereign immunity: "Because of the Eleventh Amendment, States may not be sued in federal court unless they consent to it in unequivocal terms or unless Congress, pursuant to a valid exercise of power, unequivocally expresses its intent to abrogate the [state's sovereign] immunity."[287]

For purposes of CERCLA liability, the question raised is whether the definition of "person" in CERCLA section 101(21),[288] which includes a "state,"[289] indicates an unequivocal expression of congressional intent to abrogate state sovereign immunity.

1. Union Gas *and* Conservation Chemical

The Court of Appeals for the Third Circuit recently answered this question in a different fashion before and after enactment of the 1986 Superfund Amendments. Initially, in *United States v. Union Gas Co. (Union Gas I)*,[290] a majority of a three-judge panel declared that states are immune from private cost recovery suits for monetary damages initiated under CERCLA.[291] In this case, the Union Gas Company (Union Gas) had argued that CERCLA sections 107(a) and 101(21), read together, clearly indicated that Congress intended to abolish state sovereign immunity.[292] In rejecting this argument, the *Union Gas I* majority stated:

> The United States is included in the definition of person in § 9601(21); therefore, if § 9607(a) were indeed an abrogation of states' sovereign immunity then that section would waive the United States' immunity as well. However, a separate CERCLA provision, § 96[20(a)] explicitly waives federal sovereign immunity. This implies that § 9607(a) does not waive federal immunity, for otherwise § 96[20(a)] would be superfluous.[293]

Because abrogation of a state's sovereign immunity requires a clear showing of congressional intent, the court concluded that CERCLA sections 107(a) and 101(21) did not permit the private cost recovery suit initiated by Union Gas.[294]

In a vigorous dissent, Judge Higginbotham argued that Congress's intent to abrogate state sovereign immunity in CERCLA cost recovery actions was clear:

> When a statute in its definitional section declares unequivocally that the term "person" includes a *State* . . . the explicit language of Congress should not be disregarded where there is no legislative history suggesting that Congress did not mean what they said when they used the word "state." Instead of giving Congress the presumption that they know what a state is, the majority seems to assume that judges have a better mastery and understanding of the English language than does Congress, and thus they roam through inconclusive legislative history to "demonstrate" that Congress did not mean state when they included that specific phrase in the key definitional section of the statute.[295]

With the passage of the 1986 Superfund Amendments, the Supreme Court vacated the decision below and remanded to the Third Circuit for reconsideration.[296] In *United States v. Union Gas Co. (Union Gas II)*,[297] the Third Circuit concluded that the new definition of "owner or operator" in CERCLA after the SARA amendments[298] compelled the unmistakable conclusion that Congress intended to abrogate state sovereign immunity so that states would be subject to suit as would any other party.[299]

---

would support an argument that the Eleventh Amendment is inapplicable in this case. *See also* Tribe, *Intergovernmental Immunities in Litigation, Taxation, and Regulation: Separation of Powers Issues in Controversies About Federalism*, 89 HARV. L. REV. 682, 686 (1976) (stating that "in ratifying the constitutional plan, the states surrendered sovereign immunity from suits testing the constitutional limits of state action" (footnote omitted)).

285. *Pennhurst*, 465 U.S. at 98-99.

286. *Id.*; *see also* Franchise Tax Bd. v. United States Postal Serv., 467 U.S. 512, 525 (1983) (holding that the statutory provision that the Postal Service can "sue and be sued" waives soverign immunity in administrative proceedings as well as in federal court); United States v. Mitchell, 445 U.S. 535, 539 (1980) (noting that the United States, as sovereign, is immune from suit absent its consent), *aff'd*, 463 U.S. 206 (1983).

287. Green v. Mansour, 474 U.S. 64, 68 (1985) (citing Pennhurst State School & Hosp. v. Halderman, 465 U.S. 89, 99 (1984)).

288. 42 U.S.C. § 9601(21) (1982 & Supp. IV 1986).

289. *Id.*

290. 792 F.2d 372 (3d Cir. 1986).

291. In *Union Gas I*, the United States sued the Union Gas Company (Union Gas) in federal court under CERCLA to recoup $450,000 in response costs and under the Clean Water Act to recover $270,000 in damages. As to the amount claimed under CERCLA, Union Gas filed a third-party complaint against the state and the borough, claiming that they "negligently caused, or contributed to, the discharge of coal tar into Brodhead Creek" by their recent excavation and earlier construction of levees and dikes, and thus were liable for the cleanup costs. *Id.* at 374-75.

292. *Id.* at 379. The argument proceeds as follows: (1) section 107(a) states that "any person who owns or operates a hazardous waste site is liable for clean-up costs;" (2) "the state owns the land . . . where the hazardous waste is deposited;" (3) section 101 specifies that "a state is a person for purposes of CERCLA;" therefore (4) "the state is jointly liable for the costs of the clean-up." *Id.*

293. *Id.*

294. *Id.* at 380.

295. *Id.* at 383. The provision in CERCLA waiving federal immunity was originally codified at 42 U.S.C. § 9607(g). Due to later amendments, however, that provision can be found at 42 U.S.C. § 9620(a). 42 U.S.C. §§ 9607(g), 9620(a) (1982 & Supp. IV 1986).

296. Union Gas v. Pennsylvania, 479 U.S. 1025 (1987).

297. 832 F.2d 1343 (3d Cir. 1987).

298. SARA § 101(b)(1), (f), 42 U.S.C. § 9601(20)(D) (Supp. IV 1986).

299. *Union Gas II*, 832 F.2d at 1350. The court was critical of the fact that the congressional waiver of states' sovereign immunity was found in a definitional section rather than in the body of the Act. However, the court concluded that the definition evidenced a clear congressional intent. *See id.* at 1348-49.

The fact that Congress did not specifically waive state sovereign immunity from citizen suits to enforce CERCLA convinced the court in *Union Gas II* that Congress otherwise intended immunity to be waived. The court found that SARA's legislative history corroborated this view[300] and dismissed any problem with the new law's retroactive application.[301] At the state's request, the Supreme Court on March 21, 1988 granted certiorari to again review this decision.[302] Seventeen states joined Pennsylvania's request.[303]

Although decided prior to SARA's enactment, the district court in *United States v. Conservation Chemical Co*[304] reached the same conclusion as the court in *Union Gas II*. In *Conservation Chemical*, the court concluded that CERCLA's legislative history indicated a clear congressional intent to abrogate state immunity in citizen suits to enforce CERCLA.[305] In that case the original generator defendants had become third-party plaintiffs seeking a ruling that would hold other responsible parties, including the state, liable to the defendants for a portion of the response costs that they would incur.[306] Following the recommendations of a Special Master, the court construed CERCLA sections 107(a) and 101(21) and found that Congress, when passing CERCLA, intended to waive both state and federal governmental immunity.[307]

2. *The 1986 Superfund Amendments (SARA)*

The 1986 Superfund Amendments, enacted after both *Union Gas I* and *Conservation Chemical*, contain two provisions affecting the survival of Eleventh Amendment immunity.[308] First, the general sav-

300. *Id.* at 1349; *see* H.R. CONF. REP. No. 962, 99th Cong., 2d Sess. 185-86, *reprinted in* 1986 U.S. CODE CONG. & ADMIN. NEWS 3276, 3278-79. However, this legislative history contains, at best, an implied rather than an express waiver of sovereign immunity.

301. *Union Gas II*, 832 F.2d at 1356-57. The law in effect at the time of appeal is to be applied, even if it has evolved or is contrary to the law at the time of original trial court decision. *Id.*; *see* United States v. Schooner Peggy, 5 U.S. (1 Cranch) 103, 110 (1801); Dedham Water Co. v. Cumberland Farms Dairy, Inc., 805 F.2d 1074, 1084 (1st Cir. 1986).

302. Pennsylvania v. Union Gas Co., 108 S. Ct. 1219 (1988).

303. *See Supreme Court to Hear Pennsylvania Case Disputing States' Immunity Under CERCLA*, Toxics L. Rep. (BNA) 1183, 1183 (Mar. 30, 1988).

304. 9 Chemical & Radiation Waste Litigation Rep. 945 (W.D. Mo. Mar. 13, 1985) (denying third party defendants' motions to dismiss on the basis of sovereign immunity).

305. *See id.* at 950 (Special Master's recommendation regarding the sovereign immunity motions). The Special Master's recommendation was independently reviewed and adopted by the court. *Id.* at 945. For a recent decision *contra*, see United States v. Freeman, 680 F. Supp. 73, 77-78 (W.D.N.Y. 1988) (holding that Congress has no power to abrograte Eleventh Amendment immunity under the Commerce Clause).

306. *Conservation Chem. Co.*, 9 Chemical & Radiation Waste Litigation Rep. at 947. All four governmental entities which were joined as third-party defendants—the City of Wichita, Kansas, the City of Pleasant Hill, Missouri, the University of Kansas, and the curators of the University of Missouri—filed motions to dismiss the third-party complaint on grounds of sovereign immunity. *Id.*

307. *See id.* at 950 (Special Master's recommendation) (concluding that the "explicit inclusion of states and their political subdivisions as 'persons' potentially liable to private parties under § 107 is clear evidence of Congress's intent to abrogate Eleventh Amendment protection"); *see also id.* at 945 (adopting the Special Master's recommendation).

308. The legislative history of SARA is silent on both of these contradictory decisions. *See generally* H.R. CONF. REP. No. 962, 99th Cong., 2d Sess. 183, *reprinted in* 1986 U.S. CODE CONG. & ADMIN. NEWS 3276 [hereinafter SARA CONFERENCE REPORT].

ings clause in the 1986 Superfund Amendments provides that nothing in the Amendments "shall . . . affect or modify in any way the obligations or liabilities of any person under other Federal law."[309] The Conference Report does not explain this provision.[310] This could be read to reinforce the *Union Gas I* majority's demand for an express unequivocal waiver of state sovereign immunity.

Second, the 1986 Superfund Amendments enunciate that state or local governments are not liable as owners or operators if they inherit the site in their capacity as sovereign, assuming they do not in any way contribute to contamination at the site.[311] The amendments do add, however, that a

> State or local government which has caused or contributed to the release or threatened release of a hazardous substance from the facility . . . shall be subject to the provisions of this Act in the same manner and to the same extent, both procedurally and substantively, as any nongovernmental entity, including liability under section 107.[312]

SARA's legislative history sheds little light on Congress's reasons for adding these provisions.[313] However, these modifications appear to support the contention that Congress intended to waive sovereign immunity under CERCLA, although there is no express waiver of immunity in this language. Rather, such waiver is implied by the affirmative statement of local liability if there is any causal contribution by a governmental entity. The SARA Conference Report confirms that state and local governments that dispose of their wastes at a site are liable for contribution under section 113.[314] In a later section of the amendments, citizen suits are authorized to the extent permitted by the Eleventh Amendment.[315] Whether Congress waived Eleventh Amendment state sovereign immunity, therefore, remains in some dispute.

By their own actions, states may also waive their Eleventh Amendment immunity.[316] In *United States v. Mottolo*,[317] a New Hampshire

district court found an implied waiver of sovereign immunity when the state initiated suit as party plaintiff against PRP defendants, thereby impliedly waiving its Eleventh Amendment immunity as to any related counterclaim or defense arising out of the same event.[318] Therefore, the state, by initiating or joining prosecution, may not assert sovereign immunity as a defense to a related counterclaim to its own liability.[319] The waiver in *Mottolo*, however, would not extend to a private PRP seeking contribution where damages are owed solely to the United States as plaintiff or to unrelated affirmative claims.[320]

B. *Municipal and Local Governmental Immunity*

Sovereign immunity under the Eleventh Amendment extends to state agencies and departments.[321] Some non-state agencies exercising state power are also permitted to invoke the Eleventh Amendment to protect the state treasury from liability that would have essentially the same practical consequences as a judgment against the state itself.[322] Whether the state is "the real party in interest" is a question of federal law in Eleventh Amendment cases, and federal courts must examine the powers, characteristics, and relationships created by state law in order to determine whether the suit is, in reality, against the state itself.[323] Local governmental entities could, in limited circumstances, be considered an arm of the state, thereby invoking the protection of the state's Eleventh Amendment immunity.[324] To determine whether the suit is against the state, and therefore barred by the Eleventh Amendment, courts typically consider the degree of local autonomy and control and whether the funds to defray an award would be derived from the state treasury.[325]

The Supreme Court has consistently refused to construe the Eleventh Amendment as affording protection to political subdivisions such as counties and municipalities, although such entities exercise a "slice of state power."[326] Similarly, one district court ruled that Eleventh Amendment sovereign immunity does not extend to independent political entities of the state, municipalities, or local enti-

317. 605 F. Supp. 898 (D.N.H. 1985).
318. *Id.* at 910-11.
319. With only one district court opinion as precedent, however, other states could dispute this implied waiver concept.

ties created by municipal authority in CERCLA actions.[327] By its terms, Eleventh Amendment protection is only available to "one of the United States."[328] A municipality that owns or operates a hazardous waste site should not be able to raise Eleventh Amendment immunity as a defense to a private action initiated under CERCLA to recover cleanup expenses.[329]

No independent source of municipal sovereign immunity exists, notwithstanding the Eleventh Amendment. In the early nineteenth century, local governmental officials claimed that counties, cities, and other municipal corporations should benefit from sovereign immunity to protect these local governments from suits in the federal courts. The Supreme Court has held on numerous occasions that political subdivisions do not have the benefit of sovereign immunity.[330] Local governments are considered municipal corporations; they exist at the pleasure of the state and have never been considered sovereigns in their own right.[331] As such, they may sue and be sued. Moreover, outside the realm of CERCLA liability, the Supreme Court has concluded that there is no tradition of immunity for municipal corporations and that neither history nor policy supports granting immunity to municipalities when a statute is otherwise silent.[332] A municipality should therefore not be afforded governmental immunity as a defendant in a CERCLA suit.

Although a municipality may not have independent sovereign immunity, two doctrines exist that afford municipalities, in limited situations, protection from tort liability by affording them protection under the state's immunity.[333] The first doctrine distinguishes be-

327. United States v. Conservation Chem. Co., 9 Chemical & Radiation Waste Litigation Rep. 945, 948 (W.D. Mo. Mar. 13, 1985) (Special Master's recommendation regarding sovereign immunity motions, adopted by the court after independent review).
328. U.S. CONST. amend. XI.
329. This lack of Eleventh Amendment immunity from suits by third parties is distinct from municipalities' rights as plaintiffs under CERCLA. State, and in some cases municipal, governmental entities exerting enforcement powers can recover expenditures under CERCLA section 107. *See* New York v. Shore Realty Corp., 759 F.2d 1032, 1047 (2d Cir. 1985). One court construed municipalities as "states" for purposes of plaintiff cost recovery based on a broad reading of the remedial goals of CERCLA. Mayor of Boonton v. Drew Chem. Corp., 621 F. Supp. 663, 665 (D.N.J. 1985). Another court, however, found that municipalities could not avail themselves of "state" status, but still allowed them to recover costs as would a private plaintiff who incurred cleanup expenses under CERCLA. City of Philadelphia v. Stepan Chem. Co., 544 F. Supp. 1135, 1140-43 (E.D. Pa. 1985).
330. Cowles v. Mercer County, 74 U.S. (7 Wall.) 118, 121 (1868); Levy Court v. Coroner, 69 U.S. (2 Wall.) 501, 507-08 (1864); Weightman v. Washington, 66 U.S. (1 Black) 39, 49-52 (1861).
331. Cooper, *The Supreme Court on Governmental Liability*, 16 ADMIN. & SOCIETY 259, 273 (1984).
332. *See* Owen v. City of Independence, 445 U.S. 622, 638 (1980) (holding that municipalities may not assert "good faith" qualified immunity under the Civil Rights Act of 1873, 42 U.S.C. § 1983 (1982)).
333. *See generally Owen*, 445 U.S. at 644-50 (discussing the application of two common

tween a municipality's "governmental" and "proprietary" functions.[334] A city is immune from suit for actions undertaken in its governmental capacity; however, when exercising its proprietary functions, a city is held to the same standards of liability as those applied to private corporations.[335] The second doctrine provides a municipality with absolute immunity from suits stemming from its "discretionary" or "legislative" activities, but affords qualified immunity from suits arising from "executive" or "ministerial" activities.[336]

These two doctrines do not serve to immunize municipalities from liability for their share of cleanup costs under CERCLA. First, garbage collection services provided by cities are not traditionally considered exclusively governmental functions.[337] Rather, a city is acting more properly in its proprietary capacity when it provides such services. Second, garbage collection services do not involve any legislative or discretionary action by cities or municipalities, but are rather ministerial services provided by local governments. Third, CERCLA liability is not conventional tort liability. States and municipalities that handle solid or hazardous wastes are not immune from regulation or liability under the reservation-of-rights guaranteed to the states by the Tenth Amendment.[338] The exceptions that may otherwise shield municipal activities therefore do not apply to a municipality's handling and disposal of solid and hazardous waste.

If a state enacts a statute attempting to exempt a political subdivision from liability for CERCLA offenses, that statute is ineffective. In *Lincoln County v. Luning*,[339] the Supreme Court correctly held that a state statute purporting to exempt a county from amenability to suit, except in the courts of the county, cannot defeat the federal jurisdiction granted by the Constitution.[340] By granting jurisdiction to the federal courts, CERCLA allows the courts to impose liability on political subdivisions, notwithstanding any state or local laws to the contrary.

In *Artesian Water Co. v. Government of New Castle County*,[341] a Delaware district court held that CERCLA mandated the legal responsibility of political subdivisions for the response costs incurred in taking removal or remedial action at sites owned or operated by these subdivisions.[342] In its defense, the county argued that the Delaware Tort Claims Act immunized it from an action for cleanup

law doctrines providing for municipal immunity and the policy behind each of these doctrines); Cooper, *supra* note 331, at 263-64 (same).

cost recovery under CERCLA.[343] The court found that the Delaware Tort Claims Act conflicted with the liability provisions of CERCLA, and that the Act was preempted under the Supremacy Clause of the United States Constitution.[344] Therefore, the county was not allowed to interpose the defense of state tort immunity as a bar to Artesian's claims under CERCLA. The court distinguished its decision from *Union Gas I*, because in *Artesian Water* the county conceded that it was not protected by the Eleventh Amendment, whereas in *Union Gas I* the state maintained that it was protected by Eleventh Amendment sovereign immunity.[345]

CERCLA authorizes the United States to initiate legal action against states in federal court notwithstanding the guarantees of the Eleventh Amendment.[346] The Third Circuit's decision in *Union Gas I* only protects states from being sued by private third parties. Municipalities, however, have no immunity; therefore the shield of the sovereign does not shelter municipalities that generate solid wastes from liability under CERCLA.

VII. Catch 22: When Separate is Not Equal

Without the shield of sovereign immunity at the local level, a municipality would face joint, several, and strict liability should the hazardous constituents in MSW trigger the liability provisions of CERCLA. However, there still remain a number of procedural hurdles to be surmounted before a private PRP can reach a municipality. These hurdles are not presented to the same degree when the EPA decides to prosecute municipalities.

The EPA includes municipalities as PRP-defendants when a municipality is either the current owner or operator of a dumpsite containing hazardous substances, or the previous owner or operator at the time of hazardous waste disposal.[347] The EPA does not, however, name as PRP-defendants municipal generators of MSW if the dumpsite was privately owned and received both municipal solid *and* industrial hazardous waste.[348] This category includes a significant

343. *Id.* at 1353.

344. *Id.* The Supremacy Clause requires that where state and federal law conflict, state law must yield. *See* Michigan Canners & Freezers Assoc., Inc. v. Agricultural Mktg. & Bargaining Bd., 467 U.S. 461 (1984). State law is preempted to the extent it actually conflicts with federal law, that is, when it is impossible to comply with both state and federal law, Florida Lime & Avocado Growers, Inc. v. Paul, 373 U.S. 132, 142-43 (1963); or where state law stands as an obstacle to the accomplishment of the full purposes and objectives of Congress, Hines v. Davidowitz, 312 U.S. 52, 67 (1941).

345. *Artesian Water*, 605 F. Supp. at 1355.

346. *See* 42 U.S.C. § 9601(21) (Supp. IV 1986).

348. *See supra* notes 102-40 (discussing the EPA's position regarding the cleanup of the Charles George Superfund site).

percentage of the Superfund sites included on the NPL.[349]

In those situations in which the EPA initiates prosecution, it is possible to consolidate all private and public PRPs in a single action. Yet the courts allow the EPA the discretion to name PRPs as defendants in litigation. PRPs who are not sued are not "indispensable parties" for the purpose of Rule 19 of the Federal Rules of Civil Procedure.[350] Instead, joinder of PRPs under Rule 14 impleader is possible, although permissively granted by the courts.[351] Although defendants may not succeed in forcing the EPA to name municipalities as PRPs, Rule 14 impleader and contribution actions can be utilized to bring municipalities into litigation and to impose liability on them. Indeed, the 1986 Superfund Amendments explicitly establish a right to contribution.[352]

There appears to be little long-term consequence of the EPA's

349. About 75% of the sites on the NPL will have fewer than 50 PRP generators; as many as 25% will exhibit more than 50 PRP generators. Presentation by Lee M. Thomas, EPA Assistant Administrator for Solid Waste Emergency Response & Gene A. Lucero, Director, EPA Office of Waste Programs Enforcement, Aspen Institute Conference on Superfund, Wye River Plantation, Maryland (Nov. 29-30, 1985).

Northeastern Pharmaceutical & Chem. Co., Inc. (*NEPACCO I*), 579 F. Supp. 823, 845 n.26 (W.D. Mo. 1984), *aff'd in part, rev'd in part*, 810 F.2d 726, 741 (8th Cir. 1986), *cert. denied*, 108 S. Ct. 146 (1987); United States v. A & F Materials Co., 578 F. Supp. 1249, 1261 (S.D. Ill. 1984); United States v. Cauffman, 15 Envtl. L. Rep. (Envtl. L. Inst.) 20,161, 20,161-62 (C.D. Cal. Oct. 23, 1984). In *Conservation Chem. Co.*, the court refused joinder of 46 other alleged contributing generators under Rule 19, citing the traditional rule that "one tortfeasor may not compel the joinder of other alleged joint tortfeasors." United States v. Conservation Chem. Co., 589 F. Supp. 59, 63 (W.D. Mo. 1984).

351. *See A & F Materials*, 578 F. Supp. at 1261. Joinder is permissive where liability is joint and several. *See* FED. R. CIV. P. 20. Joinder of the United States involuntarily is not permitted in CERCLA actions. *See* New Jersey Dep't of Envtl. Protection v. Gloucester Envtl. Management Servs., Inc., 26 Env't Rep. Cas. (BNA) 1443, 1445 (D.N.J. 1987); *In re* Hemingway Transport, Inc., 25 Env't Rep. Cas. (BNA) 1791, 1795 (Bankr. D. Mass. 1987).

352. 42 U.S.C. § 9613(f)(1) (Supp. IV 1986). This statute provides that

> Any person may seek contribution from any other person who is liable or potentially liable under section 9607(a) of this title, during or following any civil action under section 9606 of this title or under section 9607(a) of this title. Such claims shall be brought in accordance with . . . the Federal Rules of Civil Procedure, and shall be governed by Federal law. In resolving contribution claims, the court may allocate response costs among liable parties using such equitable factors as the court determines are appropriate. . . .

Id. The 1986 amendments provide a three-year statute of limitations for private contribution actions, running from either the date of judgment in a cost recovery action or the date of an administrative order regarding de minimus or other settlement. *Id.* § 9613(g)(3); *see also id.* § 9622(g)-(h) (providing settlement authority).

Even before CERCLA was amended, several courts and commentators had suggested that a right to contribution is consistent with CERCLA's statutory scheme. *Conservation Chemical*, 619 F. Supp. at 227-29; Wehner v. Syntex Agribusiness, Inc., 616 F. Supp. 27, 31 (E.D. Mo. 1985); United States v. South Carolina Recycling & Disposal, Inc. (*SCRDI*), 653 F. Supp. 984, 995 & n.8 (D.S.C. 1984) (dicta); United States v. Chem-Dyne Corp., 572 F. Supp. 802, 807 n.3 (S.D. Ohio 1983) (dicta); Smith, *A Right to Contribution in Superfund Cost-Recovery Actions*, 8 Chemical & Radiation Waste Litigation Rep. 41, 50 (1984); Note, *The Right to Contribution for Response Costs Under CERCLA*, 60 NOTRE DAME L. REV. 345, 357-61 (1985). The original legislative history of CERCLA also evidences a congressional concern for equitable rights of contribution. *See* 126 CONG. REC. 26,781-87, 30,932-33, 31,930-44 (1980).

prosecutorial habit of naming private, but not municipal, solid waste generators as PRPs for the cleanup of Superfund sites. The right to contribution appears to offer the possibility for all PRPs, either by cross-claims or in a later contribution action, to spread damages equitably among all those responsible.[353] Yet named defendants have several difficulties to overcome before they can successfully obtain contribution.

To begin, defendants have the burden of proving the divisibility of damages.[354] In one case, the defendants sought to apportion damages and base divisibility on waste volume; yet because the court could not determine the exact amount of chemicals or noxious matter attributable to each defendant, the court decided that the defendants' liability was joint, several and indivisible.[355] Three courts, in dicta, have also indicated that waste volume alone is not an appropriate basis for the division of damages.[356] These courts suggest that the division of damages must be based on risk, toxicity, and migratory potential.[357] This may be a difficult, if not impossible, burden for a PRP to sustain.

Defendants seeking contribution may also be thwarted by several affirmative defenses. Although CERCLA recognizes only three statutory defenses,[358] *all* equitable defenses should be fully available in contribution actions for purposes of apportioning liability.[359] Con-

353. 42 U.S.C. § 9613(f)(1) (Supp. IV 1986).

354. *SCRDI*, 653 F. Supp. at 994; United States v. Ottati & Goss, Inc., 630 F. Supp. 1361, 1395-96 (D.N.H. 1985); Colorado v. ASARCO, Inc., 608 F. Supp. 1484, 1487-91 (C.D. Colo. 1985); United States v. Wade, 577 F. Supp. 1326, 1337-39 (E.D. Pa. 1983); United States v. Chem-Dyne Corp., 572 F. Supp. 802, 810-11 (S.D. Ohio 1983); *see* United States v. Dickerson, 640 F. Ill. 1984) (adopting Gore amendment legislative history for apportionment).

355. *Ottati & Goss*, 630 F. Supp. at 1396. *But see* Advance Circuits, Inc. v. Carriere Properties, No. C8-87-1436 (Minn. Ct. App. Feb. 9, 1988) (unpublished opinion) (LEXIS, States library, Minn file) (apportioning liability for costs among site owners and generators).

356. *See SCRDI*, 653 F. Supp. at 994-95; *A & F Materials*, 578 F. Supp. at 1256; *Chem-Dyne Corp.*, 572 F. Supp. at 811.

357. In *A & F Materials*, 578 F. Supp. at 1255-57, the court makes reference to the amendment proposed by Representative Gore that was not enacted. The Gore amendment would have permitted a court to divide liability according to criteria of due care exercised, toxicity and volume of waste, direct responsibility of the PRP in the disposal activity, and other factors. *Id.*

358. *See supra* note 257.

359. *Cf.* United States v. Conservation Chem. Co., 619 F. Supp. 162, 204-06 (W.D. Mo. 1985) ("Equitable defenses are proper under CERCLA in determining liability, the nature of the remedy and the amount of damage."); Marden Corp. v. C.G.C. Music Ltd., 600 F. Supp. 1049, 1057-58 (D. Ariz. 1984) (dismissing CERCLA claim on basis of equitable defense of unclean hands). *But see* Mola Dev. Corp. v. United States, 22 Env't Rep. Cas. (BNA) 1443, 1447 (C.D. Cal. 1985) (implying that only the three statutory defenses are available in private cost recovery actions). For a discussion of equitable defenses, see *supra* notes 257-61.

sequently, the litigation process of apportioning liability in a distinct contribution action among private and public PRPs may be more convoluted and less expeditious than in a section 107 cost recovery action pursued by the EPA against all PRPs.

Further, the ability of private PRPs to reach public PRPs has not been resolved. Private PRPs can avail themselves of third-party status under CERCLA section 107.[360] Yet if the public PRP against whom contribution is sought is entitled under the evolving common law to utilize the Eleventh Amendment shield of sovereignty, a contribution action may not be available to private PRPs. If the Court's rationale in *Union Gas I* prevails,[361] state government PRPs will be able to assert their immunity to contribution claims, although municipal PRPs generally will not.

In addition, the Superfund Amendments provide the EPA with the ability to settle with selected PRPs, including the power to grant releases from additional prosecution or contribution actions.[362] This discretion, if not judiciously applied, can further compound the settlement and contribution imperfections and uncertainties facing named PRPs.

When the EPA designates selected PRPs without commencement of litigation, another dilemma confronts these named PRPs. Under CERCLA sections 104 and 106, the EPA can offer or demand that those jointly and severally liable PRPs undertake remediation activities at a contaminated site. Yet without litigation, the PRPs pursued by the EPA cannot maintain an action for contribution nor cross-claim against other PRPs ignored by the EPA. Until the named PRP incurs remediation costs consistent with the NCP, it appears that no contribution or other claim can be effectively pursued against unnamed PRPs.[363] Moreover, without litigation and the attendant discovery rights, the named PRP cannot effectively assess the strengths or weaknesses of its claims against unnamed PRPs, possible defenses, nor all the pertinent facts. It must therefore decide whether to comply with an EPA section 104 settlement offer or section 106 order in a partial vacuum.

In such a situation, a Catch-22 exists. If a named PRP elects not to engage voluntarily in early remedial actions, the remediation eventually imposed on the PRP by the EPA may be more expensive than necessary.[364] In addition, the PRP may be liable for treble

361. *See supra* text accompanying notes 290-94.

362. 42 U.S.C. §§ 9613(f)(2), 9622(f)-(g) (Supp. IV 1986).

363. Artesian Water Co. v. Government of New Castle County, 659 F. Supp. 1269, 1291-92 (D. Del. 1987), *aff'd*, 851 F.2d 643 (3d Cir. 1988); Pinole Point Properties, Inc. v. Bethlehem Steel Corp., 596 F. Supp. 283, 286, 289-90 (N.D. Cal. 1984); United States v. Northeastern Pharmaceutical & Chem. Co. (*NEPACCO I*), 579 F. Supp. 823, 850-51 (W.D. Mo. 1984), *aff'd in part, rev'd in part*, 810 F.2d 726 (8th Cir. 1986), *cert. denied*, 108 S. Ct. 146 (1987); Dedham Water Co. v. Cumberland Farms Dairy, Inc., 588 F. Supp. 515, 517-18 (D. Mass. 1983).

364. It is generally thought that EPA-initiated actions are more expensive than identical PRP-initiated cleanups. Yet to date, no district court has agreed to enjoin a cleanup action ordered by the EPA on the grounds that its costs were excessive or inappropriate.

damages due to the violation of an EPA administrative order.[365] On the other hand, it is difficult for a PRP to voluntarily commit to a remediation effort before knowing the capability and willingness of unnamed PRPs to contribute.

The lack of interlocutory review of EPA administrative decisions, statutorily enshrined by the 1986 Superfund amendments, compounds this dilemma.[366] Although PRPs in a section 107 cost recovery action may challenge any costs incurred for cleanup undertaken to comply with the EPA's directives,[367] the courts will not sanction this review until all cleanup costs are incurred.[368] To make informed and cost-effective settlement and remediation decisions at Superfund sites, a PRP needs to know at least two important facts: what the cost is and who will share in the payment of that cost. Without litigation, a PRP who ignores a section 104 offer or a section 106 demand does not know, and loses control over, eventual remediation costs. Conversely, a PRP who elects to effect remediation does not know how many other parties will share in the costs at the time critical cleanup decisions are made. Without both pieces of

Even when courts have found that EPA-imposed cleanup actions are arbitrary and capricious, they have refused to halt their completion. *See* Industrial Park Dev. Co. v. EPA, 604 F. Supp. 1136, 1143-44 (E.D. Pa. 1985) (denying plaintiff's motion for preliminary relief, in spite of plaintiff's strong showing of EPA's arbitrary and capricious behavior, because plaintiff failed to show that irreparable injury would occur absent injunctive relief). Instead, the court in *Industrial Park* held that the propriety of the EPA cleanup would be an issue for cost recovery against the PRP under section 106. *Id.* at 1145. For a discussion of EPA's cleanup actions priced at more than the least available cost, see *supra* note 190.

365. 42 U.S.C. §§ 9606, 9607(c)(3) (1982).

366. SARA § 113(c), 42 U.S.C. § 9613(h) (Supp. IV 1986). Several courts have heard preenforcement challenges to section 106 administrative orders as violative of fundamental due process rights under the statute. The courts reaching the question are split. The courts in United States v. Reilly Tar & Chemical Corp., 606 F. Supp. 412 (D. Minn. 1985), and in Wagner Electric Corp. v. Thomas, 612 F. Supp. 736 (D. Kan. 1985), found that PRPs raising good faith challenges to section 106 administrative orders have "sufficient cause" to obviate treble damages; other courts, notably Aminoil, Inc. v. EPA, 599 F. Supp. 69, 75 (C.D. Cal. 1984) and Industrial Park Development Co. v. EPA, 604 F. Supp. 1136 (E.D. Pa. 1985) (motion for summary judgment), found the statutory scheme of daily penalties and treble damages to have a coercive effect violative of fundamental due process.

Under RCRA, whose cleanup actions are not predicated on "imminent and substantial endangerment," one court suggests that preenforcement review may be appropriate. *See* E.I. duPont de Nemours & Co. v. Daggett, 610 F. Supp. 260, 263 (W.D.N.Y. 1985).

368. *Id.* EPA Records of Decisions, the government plan implementing cleanup, are not reviewable. Lone Pine Steering Comm. v. EPA, 600 F. Supp. 1487 (D.N.J.), *aff'd*, 777 F.2d 882 (3d Cir. 1985), *cert. denied*, 476 U.S. 1115 (1986); United States v. Outboard Marine Corp., 104 F.R.D. 405 (N.D. Ill. 1984), *aff'd*, 789 F.2d 497 (7th Cir.), *cert. denied*, 479 U.S. 961 (1986); *cf.* United States v. United Nuclear Corp., 610 F. Supp. 527 (D.N.M. 1985) (holding that the EPA determination that hazardous substances were being released was not final agency action and thus was not subject to judicial review). Similarly, conduct of the government's Remedial Investigation and Feasibility Study (RI/FS) is not independently reviewable. *Id.* at 528; Wheaton Indus. v. EPA, 15 Envtl. L. Rep. (Envtl. L. Inst.) 20,950 (D.N.J. July 11, 1985).

...formation, an effective and equitable settlement and remediation process is hampered.

VIII. Household Waste: RCRA Doublespeak

If municipalitites arranging for disposal of MSW can be PRPs under CERCLA, the factual and legal issue remains: Is MSW a legally hazardous substance?[369] As a matter of prosecutorial discretion, the EPA uniformly answers this question in the negative in scores of prosecutions nationwide. The EPA's answer allocates responsibility for hundreds of billions of dollars of long-term liability solely to private PRPs at mixed public/private sites. This Article contends that the EPA's interpretation of this critical CERCLA enforcement responsibility is legally unsound.

As a general rule, the EPA's construction of CERCLA's liability provisions should be accorded deference by a reviewing court.[370] When sufficiently reasonable, the EPA's construction should be respected absent clear congressional intent to the contrary.[371] However, an agency's reversal of its internal enforcement position mitigates against judicial deference to the agency's position.[372] As demonstrated below, the EPA has taken contradictory enforcement positions on the issue of municipal liability for hazardous constituents in MSW.[373] In light of this conflict, there is no uniform agency interpretation to which a court can properly defer.

In the absence of clear statutory guidance, courts should determine congressional intent.[374] CERCLA's original legislative history, however, contains no language clarifying the liability status of municipalities.[375] Although there is a vague reference to municipal liability in the 1986 Superfund Amendments, the legislative history of the amendments fails to explain this reference.[376] The Supreme Court has stated that "[s]ubsequent legislation declaring the intent of an earlier statute is entitled to great weight in statutory construction."[377] However, if that subsequent legislation is equally ambiguous, it provides little guidance.[378] Moreover, according to the Supreme Court, " '[i]t is the intent of the Congress that enacted [the section] that controls' " and not the intent of a subsequent Congress.[379] A reviewing court must therefore fashion congressional intent from the whole cloth of the originally enacted CERCLA.

369. *See generally* Gaynor, *Municipalities as PRPs: Changing the Dynamics of Selecting the Remedy*, Toxics L. Rep. (BNA) 375 (Aug. 17, 1988) (discussing EPA's increased attention to the emerging problems that municipal landfills and the treatment of municipalities present in the Superfund program).

370. *See* Chevron U.S.A. Inc. v. Natural Resources Defense Council, Inc., 467 U.S. 832, 842-66 (1984); Bulk Distrib. Centers, Inc. v. Monsanto Co., 589 F. Supp. 1437, 1448 (S.D. Fla. 1984).

A. CERCLA's Additive Definition of "Hazardous Substance"

In its haste for passage, Congress avoided fashioning a prescriptive definition of "hazardous substances" that CERCLA would regulate. Rather, Congress chose to include by reference all substances that the EPA deemed hazardous pursuant to four existing statutes. This also vested the EPA with lead agency administrative responsibilities.[380]

CERCLA's definition of a hazardous substance is additive. Any substance that falls within one of five definitional references is a hazardous substance for CERCLA purposes.[381] Moreover, even if a substance is purposely excluded from the hazardous substance defi-

380. For examples of delegation of lead agency responsibility, see TSCA § 26, as amended, 15 U.S.C. § 2625 (1982 & Supp. IV 1986); Federal Water Pollution Control Act, § 501, 33 U.S.C.A. § 1361 (West 1986 & Supp. 1988); RCRA § 3008, 42 U.S.C. § 6928 (1982 & Supp. IV 1986); CERCLA § 106, 42 U.S.C. § 9606 (1982 & Supp. IV 1986).

381. CERCLA defines a hazardous substance as:

> (A) any substance designated pursuant to section 1321(b)(2)(A) of title 33, (B) any element, compound, mixture, solution or substance designated pursuant to section 9602 of this title, (C) any hazardous waste having the characteristics identified under or listed pursuant to section 3001 of the Solid Waste Disposal Act [42 U.S.C. 6921] (but not including any waste the regulation of which under the Solid Waste Disposal Act [42 U.S.C. 6901 et seq.] has been suspended by Act of Congress), (D) any toxic pollutant listed under section 1317(a) of title 33, (E) any hazardous pollutant listed under section 112 of the Clean Air Act [42 U.S.C. 7412], and (F) any imminently hazardous chemical substance or mixture with respect to which the Administrator has acted pursuant to section 2606 of title 15.

42 U.S.C. § 9601(14) (Supp. IV 1986).

nition under one reference, it is still a hazardous substance under CERCLA if it is included by another.[382]

By far the most comprehensive list of hazardous substances that CERCLA incorporates by reference is that maintained pursuant to RCRA.[383] RCRA and CERCLA are interwoven in a helix legal definition: RCRA forms the messenger RNA that carries the definitional lifecode to CERCLA enforcement actions.

1. CERCLA's Incorporation of RCRA's Provisions

RCRA is a complex statute. Enacted in 1976 to protect the public health and to encourage the recycling, reuse, and treatment of hazardous wastes,[384] RCRA requires that anyone who generates,[385] transports,[386] treats, stores, or disposes[387] of hazardous wastes must notify the EPA and comply with RCRA requirements.[388]

a. RCRA's Regulatory Structure

The EPA's primary responsibilities under RCRA are ministerial, including issuing permits for the handling, transportation, storage, and disposal of hazardous wastes,[389] as well as inspection, testing,

382. *See infra* text accompanying notes 431-42. By statute, the term "hazardous substance" does not include: "petroleum, including crude oil or any fraction thereof which is not otherwise specifically listed or designated as a hazardous substance . . . and the term does not include natural gas, natural gas liquids, liquefied natural gas, or synthetic gas usable for fuel (or mixtures of natural gas and such synthetic gas)." *Id* § 9601(14) (Supp. IV 1986).

383. *Id* §§ 6901-6987 (1982 & Supp. IV 1986).

384. *Id* § 6902 (Supp. IV 1986). In RCRA section 1003, as amended, Congress declares it to be the national policy that, "wherever feasible, the generation of hazardous waste is to be reduced or eliminated as expeditiously as possible. Waste that is nevertheless generated should be treated, stored, or disposed of so as to minimize the present and future threat to human health and the environment." *Id* § 6902(b).

385. *Id* § 6922. RCRA section 3002, as amended, states that the EPA "shall promulgate regulations establishing such standards applicable to generators of hazardous waste . . . as may be necessary to protect human health and the environment." *Id* § 6922(a). These standards are set forth in 40 C.F.R. § 262 (1988).

386. 42 U.S.C. § 6923 (1982 & Supp. IV 1986). RCRA section 3003, as amended, requires the EPA to promulgate standards to govern transporters of hazardous waste. *Id.* § 6923(a). These standards are set forth in 40 C.F.R § 263 (1988).

387. 42 U.S.C. § 6924 (Supp. IV 1986). RCRA section 3004, as amended, authorizes the EPA to establish regulations applicable to owners and operators of hazardous waste treatment, storage and disposal facilities. The regulations require that accurate records be kept of the types of hazardous wastes that are treated, stored and disposed of at the facility, and that the manner in which these hazardous wastes are treated, stored and disposed conform to methods approved by the EPA. In addition, the location, design and construction of the facilities must meet with EPA's approval. The owners and operators of such facilities are also responsible for adequately training personnel and having the financial assets available for corrective action when necessary. *Id* § 6924(a)

388. §§ 6902, 6922-6924 (1982 & Supp. IV 1986)

389. *Id* § 6925. RCRA section 3005, as amended, requires the EPA to "promulgate regulations requiring each person owning or operating an existing facility or planning to construct a new facility for the treatment, storage or disposal of hazardous waste" to obtain a permit. *Id.* § 6925(a) (Supp. IV 1986). This section also allows the EPA to determine what information an applicant for a permit must provide, including information concerning estimates of the "composition, quantities and concentrations of hazardous waste . . . proposed to be disposed of, treated, transported or stored," as well as the frequency and rate at which such operations will take place. *Id* § 6925(b) (1982). Under this section, permits are to be issued for a fixed term (not to exceed ten years).

and monitoring.[390] The EPA has delegated its primary enforcement responsibility to state environmental protection agencies in thirty-eight states,[391] where state RCRA programs impose standards that are at least as strict as federal standards. Although RCRA in its pure form is a waste management statute, RCRA as modified by Congress increasingly reflects the failure of past waste management efforts.

Due to persistent groundwater contamination problems near landfills, the 1984 amendments to RCRA[392] require a complete ban on land disposal of untreated hazardous wastes to be in effect by 1990, unless specifically exempted by the EPA after review.[393] The 1984 amendments additionally require the retrofitting of operational and existing hazardous waste surface impoundments with a double-liner, a leachate collection and groundwater monitoring system,[394] minimum technology requirements for new land disposal facilities,[395] and waste minimization and reduction efforts.[396] With

and provisions for the EPA to review an operation and its permit and to make necessary modifications to the permit are outlined. *Id* § 6925(c) (Supp. IV 1986). The EPA's regulations for such permits are set forth in 40 C.F.R § 270 (1988).

390. 42 U.S.C. § 6927 (1982 & Supp. IV 1986). RCRA section 3007, as amended, provides that any EPA representative or any representative from a state with an authorized waste program may request information and records of any person who generates, stores, treats, transports, or handles hazardous waste, and that information must be furnished. *Id* § 6927(a) (1982). To enforce the provisions of this chapter, officers, employees, or representatives of the EPA may inspect and obtain samples of hazardous wastes from places where it has been generated, stored, treated, disposed of, or transported from. *Id*
