Sunshine Canyon Landfill Draft SEIR 91-0377 ZC/GPA
SCH # 92041053

Project Description

Consisting of the development, operation, maintenance and monitoring of a Class III, non hazardous solid waste landfill (herein, City/County Landfill on proposed project). A portion of the proposed City/County Landfill footprint is located on ±194 acres within the City portion of Sunshine Canyon and provides an estimated net airspace disposal capacity of 55 million tons within the City.

Initially, the City and County landfill areas would be operated separately and provide an average daily capacity of 5,000 tons per day (tpd) in the City and 6,000 tpd in the County. However, within 18 to 24 months following the commencement of landfilling operations in the City, the City and County landfilling operations would be subsequently combined into a single landfill operation and at one working face area. This would allow for an average waste intake of 11,000 tpd. The combined development of land within both jurisdictions would result in one landfill footprint being constructed in Sunshine Canyon. The landfill footprint configuration would ultimately encompass ±451 acres.

NOTICE OF COMPLETION AND AVAILABILITY OF
DRAFT SUBSEQUENT ENVIRONMENTAL IMPACT REPORT NO. 91-0377-ZC/GPA

SITE LOCATION: 14747 San Fernando Road, Sylmar, CA 91342

A development project has been proposed for this site, for which the captioned draft subsequent environmental impact report has been prepared. The project is described at: Consisting of the development, operation, maintenance, and monitoring of a Class III, nonhazardous solid waste landfill (herein, City/Country Landfill on proposed project). A portion of the proposed City/County Landfill footprint is located on ±194 acres within the City portion of Sunshine Canyon and provides an estimated net airspace disposal capacity of 55 million tons within the City.

Initially, the City and County landfill areas would be operated separately and provide an average daily capacity of 5,000 tons per day (tpd) in the City and 6,000 tpd in the County. However, within 18 to 24 months following the commencement of landfilling operations in the City, the City and County landfilling operations would be subsequently combined into a single landfill operation and at one working face area. This would allow for an average waste intake rate of 11,000 tpd. The combined development of land within both jurisdictions would result in one landfill footprint being constructed in Sunshine Canyon. The landfill footprint configuration would ultimately encompass ±451 acres.

Anticipated significant effects on the environment are: Earth Resources, Air Quality, Surface and Groundwater, Biological Resources, Noise, Light and Glare, Land Use, Natural Resources, Risk of Upset, Population, Housing, Right-of-Way and Access, Transportation and Circulation, Public Services, Energy Conservation, Utilities, Safety, Aesthetics/View and Cultural Resources

If you wish to review a copy of the draft subsequent environmental impact report (EIR) or the documents referenced in the DEIR, you may do so at 221 N. Figueroa Street, Room 1500, Los Angeles. Copies of the DEIR are also at the following locations:

NOTICE OF COMPLETION AND AVAILABILITY OF DRAFT SUBSEQUENT ENVIRONMENTAL IMPACT REPORT NO. 91-0377-ZC/GPAS
SITE LOCATION: 14747 San Fernando Road, Sylmar, CA 91342

A development project has been proposed for this site, for which the captioned draft subsequent environmental impact report has been prepared. The project is described as: Consisting of the development, operation, maintenance, and monitoring of a Class III, nonhazardous solid waste landfill (herein, City/County Landfill or proposed project.) A portion of the proposed City/Council Landfill footprint is located on +/- 194 acres within the City portion of Sunshine Canyon and provides an estimated net airspace disposal capacity of 65 million tons within the City.

Initially the City and County landfill areas would be operated separately and provide an average daily capacity of 5,000 tons per day (tpd) in the City and 6,000 tpd in the County. However, within 18 to 24 months following the commencement of landfilling operations in the City, the City and County landfilling operations would be subsequently combined into a single landfill operation and at one working face area. This would allow for an average waste intake rate of 11,000 tpd. The combined development of land within both jurisdictions would result in one landfill footprint being constructed in Sunshine Canyon. The landfill footprint configuration would ultimately encompass +/- 451 acres.

Anticipated significant effects on the environment are: Earth Resources, Air Quality, Surface and Groundwater, Biological Resources, Noise, Light and Glare, Land Use, Natural Resources, Risk of Upset, Population, Housing, Right-of-Way and Access, Transportation and Circulation, Public Services, Energy Conservation, Utilities, Safety, Aesthetics/View and Cultural Resources.

If you wish to review a copy of the draft subsequent environmental impact report (EIR) or the documents referenced in the DEIR, you may do so at 221 N. Figueroa Street, Room 1500, Los Angeles. Copies of the DEIR are also at the following locations:

CD indicates the City Council District.

NEGATIVE DECLARATIONS
PUBLICATION OF ENVIRONMENTAL NOTICES

AD 226-97: Sobelair proposes to provide service at Los Angeles International Airport (LAX) using FAA Part 36 Stage III noise compliant B767-300 ER series aircraft. The proposed project includes 0.86 average daily passenger operations when LAX reaches 65 million annual passengers (MAP). For information, contact Los Angeles World Airports at (310) 646-3853.

AD 229-97: Aeroflot proposes to provide service at Los Angeles International Airport (LAX) using FAA Part 36 Stage III noise compliant IL96-300 series aircraft. The proposed project includes 0.6 average daily passenger operations when LAX reaches 65 million annual passengers (MAP). For information, contact Los Angeles World Airports at (310) 646-3853.

MND 241-97-PL: Zone Variance for a one-story 4 unit 3,249 square-foot auto mall with a 3,190 square-foot canopy in the R1-1 zone. Conditional Use and Commercial Corner Review for auto service station and for a 2,465 square-foot mini-market with sale of beer and wine for off-site consumption in the C2 zone, on a vacant ±30,000 square-foot (0.7 acre) lot with 10 parking spaces for the mini-market and 10 additional spaces for the auto mall. The two zones on the total project are [Q]C2-1 and R1-1. 8300 Bardwell Avenue and adjacent lots between Roscoe Boulevard and Ventura Canyon Avenue; Mission Hills - Panorama City - Sepulveda. C.D. #2. Reference No. 97-0152. (213) 580-5547. Review Period Ends: August 13, 1997. Documents are available for REVIEW at: 221 N. Figueroa Street, 15th Floor, Los Angeles, CA 90012.

MND-242-97-PL: Zone Change from [Q]C2-1 to [T][Q]M-1 for an existing truck and axle repair with two-stories and 8,790 square-feet of floor space (7,200 square-foot shop and 1,590 square-foot office) on a 33,541 square-foot (0.77 acre) lot with 22 parking spaces in the [Q]C2-1 zone. Hours of operation are 6:00 a.m. to 7:00 p.m. Monday through Saturday. 9211-9227 San Fernando Road between Wicks Street and Allegheny Street; Sun Valley. C.D #7. Reference No. 97-0154. (213) 580-5547. Review Period Ends: August 13, 1997. Documents are available for REVIEW at: 221 N. Figueroa Street, 15th Floor, Los Angeles, CA 90012.

MND-243-97-PL: Conditional Use to add a drive-through with a 40 square-foot order booth to an existing 2,572 square-foot McDonalds restaurant and a Zone Variance to encroach in the P-1VL zone as well as to relocate an existing 50-foot pole sign from C2-1VL to P-1VL on a 22,500 square-foot (0.517 acre) lot in the C2-1VL and P-1VL zones with 26 parking spaces. Hours of operation are 5:00 a.m. to 1:00 a.m. daily. 11840 Balboa Boulevard between Lorillard Street and Midwood Drive; Granada Hills - Knollwood C.D. #12. Reference No. 97-0208. (213) 580-5547. Review Period Ends: August 13, 1997. Documents are available for REVIEW at: 221 N. Figueroa Street, 15th Floor, Los Angeles, CA 90012.

MND-244-97-PL: Conditional Use to convert an existing, vacated two-story over basement 55,149 square-foot facility to a correctional facility for temporary housing of minor offenders for up to 90 days while undergoing work and educational training. There will be 108 units on a 24,135 square-foot (0.55 acre) lot with 50 parking spaces in the C2-2 zone. Hours of operation are 24 hours daily. 2307 West 6th Street between Park View Street and Grand View Street; Westlake. C.D. #1. Reference No. 97-0209. (213) 580-5547. Review Period Ends: August 13, 1997. Documents are available for REVIEW at: 221 N. Figueroa Street, 15th Floor, Los Angeles, CA 90012.

MND-245-97-PL: Conditional Use Permit for a Commercial Corner Review to permit the construction of an automobile service station with a mini-market to operate 24 hours a day, seven days a week, with less than 50% of the exterior walls having transparent windows and to allow an existing pole sign to remain on the lot. The existing service station and auto repair facility will be demolished and a new 2,929 square-foot mini-market will be built with 8 gasoline pumping stations and 9 parking spaces. 575 West Pacific Coast Highway; Wilmington-Harbor City. C.D. #15. Reference No. 97-0211. (213) 580-5547. Review Period Ends: August 13, 1997. Documents are available for REVIEW at: 221 N. Figueroa Street, 15th Floor, Los Angeles, CA 90012.

MND-246-97-PL: Conditional Use, Commercial Corner Review and Site Plan Review to demolish a 1,987 square-foot building and replace it with a new 3,220 square-foot building with (1) 3 car wash bays (2) 3 tandem smog check/auto repair bays, and (3) a snack shop, on a 12,940 square-foot (0.3 acre) lot with 14 parking spaces in the C4-1XL zone. Zone Variance to allow the newly constructed facility in the C4 zone. Yard Variance for (1) 0-foot landscape area on Melrose Avenue (2) cut corner in lieu of 5-foot landscape width required (3) delete the requirement for on-site trees on at least 50% parking area. Hours of operation are: (1) car wash: 24 hours daily (2) smog check: 7:00 a.m. to 7:00 p.m. daily (3) retail (snacks and coffee) 6:00 a.m. to 8:00 p.m. daily. 5925 Melrose Avenue between Cole Avenue and Cahuenga Avenue; Hollywood. C.D. #4. Reference No. 97-0219. (213) 580-5547. Review Period Ends: August 13, 1997. Documents are available for REVIEW at: 221 N. Figueroa Street, 15th Floor, Los Angeles, CA 90012.

DRAFT EIRs

It has been determined that the following proposed projects have a significant effect on the environment and draft Environmental Impact Reports (EIRs) have been prepared.

EIR No. 91-0377-ZC/GPA. A draft subsequent environmental impact report (EIR) has been prepared for the following project.

Project Description: Consisting of the development, operation, maintenance, and monitoring of a Class III, nonhazardous solid waste landfill (herein, City/County Landfill on proposed project). A portion of the proposed City/County Landfill footprint is located on ±194 acres within the City portion of Sunshine Canyon and provides an estimated net airspace disposal capacity of 55 million tons within the City.

Initially, the City and County landfill areas would be operated separately and provide an average daily capacity of 5,000 tons per day (tpd) in the City and 6,000 tpd in the County. However, within 18 to 24 months following the commencement of landfilling operations in the City, the City and County landfilling operations would be subsequently combined into a single landfill operation and at one working face area. This would allow for an average waste intake rate of 11,000 tpd. The combined development of land within both jurisdictions would result in one landfill footprint being constructed in Sunshine Canyon. The landfill footprint configuration would ultimately encompass ±451 acres.

Project Location: 14747 San Fernando Road, Sylmar

Significant Effects: Earth Resources, Air Quality, Surface and Groundwater, Biological Resources, Noise, Light and Glare, Land Use, Natural Resources, Risk of Upset, Population, Housing, Right-of-Way and Access, Transportation and Circulation, Public Services, Energy Conservation, Utilities, Safety, Aesthetics/View and Cultural Resources.

Council District No.: 12

Please submit any comments on the draft EIR, in writing and reference the EIR file number above, by Oct. 31, 1997 to Hadar Plafkin, City Planning Department, 221 N. Figueroa Street, Room 1500, Los Angeles, CA 90012. Copies of the documents referenced in the draft EIR, and the draft EIR, are available for review in the City Planning Department. Copies of the draft EIR are also available at the following branch libraries:

Canoga Park Branch, 7260 Owensmouth Ave., Canoga Park, CA 91303-1529
Chatsworth Branch, 21052 Devonshire St., Chatsworth, CA 91311-2314
Granada Hills Branch, 10640 Petit Ave., Granada Hills, CA 91344-6452

SACRAMENTO, CA 95826

FILED SEP 4 1997 STATE CLEARINGHOUSE

Subject: SCH# 92041053 - DRAFT SUBSEQUENT ENVIRONMENTAL IMPACT REPORT (DSEIR) FOR THE SUNSHINE CANYON LANDFILL, (SWIS# 19-AA-0853), LOS ANGELES COUNTY

California Integrated Waste Management Board (IWMB) staff have reviewed the DSEIR for the proposed expansion and operation of Sunshine Canyon Landfill. Staff's understanding of the proposed project follows:

The City of Los Angeles is designated as lead agency for the proposed project located within its jurisdiction. The County is a responsible agency for the proposed project. Upon certification of the final SEIR by the City, the County may use this document to form the environmental basis for subsequent discretionary actions.

The proposed project area is 1,102 acres; 494 acres in the City of Los Angeles, and 608 acres in the County of Los Angeles. The proposed City/County Landfill footprint in the City will occupy 194 acres within the City and then extend onto 42 acres within the County, and ultimately connect vertically and horizontally with the approved County landfill which consists of 215 acres.

Prior to or concurrent with the City/County Landfill Project approval by the City, both jurisdictions will execute an agreement that would exercise common power over the entire property (approximately 1,102 acres) and recognize existing discretionary approvals, contractual agreements or other arrangements.

Proposed uses on City acreage include the following:
1. Establishment of a green waste composting and wood waste recycling area (15 acres, 250 tons of material per day)
2. Construction of an access roadway
3. Construction of administrative offices, learning center and parking
4. Installation of a Plant Materials Center (nursery facility)
5. Installation of landfill gas flaring stations
6. Construction of leachate treatment/control systems/storage tank
7. Construction of sedimentation basins
8. Installation of a water storage tank

Proposed and existing uses on County property include the following:
1. Expansion of landfill footprint by 42 acres
2. Existing landfill footprint on 215 acres
3. Construction of an access roadway
4. Construction of administrative office and parking
5. Construction of scale house/maintenance yard
6. Installation of a water storage tank
7. Construction of leachate treatment/control systems/storage tank
8. Installation of landfill gas flaring stations
9. Removal of a sedimentation basin

Staff offer the following comments;

The Overview of the document indicates that an average of 11,000 tons per day (tpd) of waste is to be disposed at the facility. It also states that 11,000 tpd would be the maximum amount of waste accepted at the facility. The Project Description indicates an average of 11,000 tpd. Section 2.6.2 indicates that 12,100 tpd is the maximum anticipated quantity of waste deposited per operating day. What is the maximum anticipated quantity of waste to be disposed and materials to be processed at the facility? It would be helpful if a proposed maximum permitted daily tonnage instead of an average daily tonnage were consistently incorporated into the document. 1

The Project Description includes a discussion of SubTitle D requirements, and mentions the use of 30 ml high density polyethylene (HDPE) as part of the liner system. Figure 2.7-2 indicates that 60 ml HDPE would be used at this facility. In order to avoid confusion, it may be useful to state clearly which thickness of HDPE would be used as part of the liner system. 2

Section 4.1 Grading. Approximately 451 acres are to be graded, in three sequences. How much material is to be excavated? 3 Is blasting part of the excavation? If so, there may be substantial noise, air and dust impacts associated with the activity. 4 Where is the stockpiled material to be stored? 5

Grading is to take place in the expansion area, which has a potential for landslides. Construction activities would commence at the top of slide areas to retain slope stability. The landfill is in close proximity of the Santa Suzana and Northridge faults, and is in an area where liquefaction may pose a threat to landfill liner and leachate collection system integrity. 6

Although slope stability does not fall under IWMB's regulatory authority, we ask that actual design of the landfill reflect measures to minimize indirect impacts associated with potential problems with slope stability.

Thank you for the opportunity to review this document. Please contact me at (916) 255-4708 if you have any questions.

Subject: SUNSHINE CANYON LANDFILL SCH #: 92041053

Dear HADAR PLAFKIN:

The State Clearinghouse has submitted the above named draft Environmental Impact Report (EIR) to selected state agencies for review. The review period is now closed and the comments from the responding agency (ies) is (are) enclosed.

These comments are forwarded for your use in preparing your final EIR. Should you need more information or clarification, we recommend that you contact the commenting agency (ies).

This letter acknowledges that you have complied with the State Clearinghouse review requirements for draft environmental documents, pursuant to the California Environmental Quality Act. Please contact us at (916) 445-0613 if you have any questions regarding the environmental review process. Remember to refer to the project's eight-digit State Clearinghouse number so that we may respond promptly.

Sincerely,

Antero A. Rivasplata

Subject: SUNSHINE CANYON LANDFILL SEIR 91-0377 SCH #: 92041053

Dear HADAR PLAFKIN:

The State Clearinghouse has submitted the above named draft Environmental Impact Report (EIR) to selected state agencies for review. The review period is now closed and the comments from the responding agency(ies) is(are) enclosed. On the enclosed Notice of Completion form you will note that the Clearinghouse has checked the agencies that have commented. Please review the Notice of Completion to ensure that your comment package is complete. If the comment package is not in order, please notify the State Clearinghouse immediately. Remember to refer to the project's eight-digit State Clearinghouse number so that we may respond promptly. 7

Please note that Section 21104 of the California Public Resources Code required that:

> "a responsible agency or other public agency shall only make substantive comments regarding those activities involved in a project which are within an area of expertise of the agency or which are required to be carried out or approved by the agency."

Commenting agencies are also required by this section to support their comments with specific documentation.

These comments are forwarded for your use in preparing your final EIR. Should you need more information or clarification, we recommend that you contact the commenting agency(ies).

This letter acknowledges that you have complied with the State Clearinghouse review requirements for draft environmental documents, pursuant to the California Environmental Quality Act. Please contact at (916) 445-0613 if you have any questions regarding the environmental review process. 8

Sincerely,

Antero A. Rivasplata

RE: Comments on the Draft Subsequent Environmental Impact Report for the Sunshine Canyon Landfill Project - SCAG No. I 9700400

Dear Mr. Plafkin:

Thank you for submitting the **Draft Subsequent Environmental Impact Report for the Sunshine Canyon Landfill Project** to SCAG for review and comment. As areawide clearinghouse for regionally significant projects, SCAG assists cities, counties and other agencies in reviewing projects and plans for consistency with regional plans.

The attached detailed comments are meant as administrative comments to provide guidance for considering the proposed project within the context of our regional goals and policies. SCAG's policy level review will be initiated with the presentation of the proposed Sunshine Canyon Landfill Project to SCAG's Standing Committee on Implementation (SCI) on October 9, 1997 at 11:15 am at the SCAG office in Los Angeles. You are cordially invited to attend this meeting and answer any questions of the elected official members of the SCI. If you have any questions regarding the attached comments, please contact Bill Boyd at (213) 236-1960. He will be contacting you with further information concerning this SCI meeting.

Sincerely,

J. DAVID STEIN
Manager, Performance Assessment
and Implementation

JDS:lj

**COMMENTS ON THE CITY OF LOS ANGELES
SUNSHINE CANYON LANDFILL
DRAFT SUBSEQUENT ENVIRONMENTAL IMPACT REPORT**

PROJECT DESCRIPTION

The proposed Project consists of the development , operation, maintenance, and monitoring of a Class III, nonhazardous solid waste landfill (City/County Landfill). The Project site is located in Sunshine Canyon, due south of the intersection of Interstate 5 and the State Route 14 junction. It is accessible off of San Fernando Road. A portion of the proposed City/County Landfill footprint is located on approximately 194 acres within the City of Los Angeles (City). In order to facilitate the design of the proposed project, an area of approximately 42 acres in the County of Los Angeles (County) would be developed. This acreage would be engineered to ultimately connect, both vertically and horizontally, to the proposed landfill in the City and the operational County Landfill (existing landfill footprint of approximately 215 acres).

Initially, these landfill areas would be operated separately and provide an average daily capacity of 5,000 tons per day (tpd) in the City and 6,000 tpd in the County. Within 18 to 24 months, following the commencement of landfilling operations in the City, landfilling operations would be combined into a single landfill operation and at one working face area. This would allow for an average waste intake rate of 11,000 tpd. This landfill footprint configuration would ultimately encompass approximately 451 acres and result in a net disposal capacity of 90 million tons. This footprint includes the operational County Landfill with an approved permitted capacity of 17 million tons.

The landfill would be operated 16 hours per day (i.e., 5:00 a.m. to 9:00 p.m., Monday through Saturday), 6 days per week, two shifts per day. At maximum operation, the landfill would employ 35 people, in addition to the 52 employees currently employed at the County Landfill.

The Project also consists of developing and operating numerous ancillary areas and facilities to support landfilling operations at the City/County Landfill. These would include: administrative offices, caretaker trailer, lunchroom/locker building, employee parking, environmental learning center, green waste/wood waste recycling area, plant materials center (or nursery) , scale house and check-in facility. The following environmental protection and control systems would be installed during the development of the City/County Landfill: subdrain system, foundation layer, liner system, leachate collection and removal system, surface water drainage controls, sedimentation basin, landfill gas collection and flaring system, and groundwater protection.

In order to eliminate potential environmental impacts, the proposed Project includes a number of

disposal site control measures or features, including: litter prevention and control, dust abatement, vector and bird control, noise control, odor control, fire control, hazardous waste exclusion and visual/landscaping buffer areas. In addition to these control measures or features, basic safety features would be provided, such as emergency shutoffs for all equipment, interlocking systems, for safe, coordinated startup and shutoff of connected equipment systems, protective covers for all exposed moving equipment, and adequate on-site safety features.

It is anticipated that a majority of the incoming wastes disposed of at the landfill would be generated in the City, surrounding communities proximate to the project site, and unincorporated areas in the County. It is also expected that refuse may be generated by other jurisdictions within the Los Angeles region. The primary form of refuse transport to the site would be transfer trucks from existing transfer stations/MRFs that are either owned, operated , or leased by the project proponent (Browning-Ferris Industries of California, Inc.). In addition to that traffic flow, wastes would be transported by municipal and private refuse-hauling vehicles collecting solid waste from various incorporated jurisdictions and unincorporated communities.

Alternatives to the proposed project include:

- No Project,
- Reduced Volume,
- Immediate Combined City/County Landfill Operations,
- Potential/Proposed Landfill Sites in Los Angeles County,
- Out-of- County Landfill Sites,
- Waste Management Technologies and Strategies,
- Remote Landfill Facilities In-State/Out-of-State

INTRODUCTION TO SCAG REVIEW PROCESS

The document that provides the primary reference for SCAG's project review activity is the Regional Comprehensive Plan and Guide (RCPG). The RCPG chapters fall into three categories: core, ancillary, and bridge. The Growth Management (adopted June 1994), Regional Mobility (adopted June 1994), Air Quality (adopted October 1995), Hazardous Waste Management (adopted November 1994), and Water Quality (adopted January 1995) chapters constitute the core chapters. These core chapters respond directly to federal and state planning requirements. The core chapters constitute the base on which local governments ensure consistency of their plans with applicable regional plans under CEQA. The Air Quality and Growth Management chapters contain both core and ancillary policies, which are differentiated in the comment portion of this letter. The Regional Mobility Element (RME) constitutes the region's Transportation Plan. The RME policies are incorporated into the RCPG.

Ancillary chapters are those on the Economy, Housing, Human Resources and Services, Finance, Open Space and Conservation, Water Resources, Energy, and Integrated Solid Waste Management. These chapters address important issues facing the region and may reflect other regional plans.

Ancillary chapters, however, do not contain actions or policies required of local government. Hence, they are entirely advisory and establish no new mandates or policies for the region.

Bridge chapters include the Strategy and Implementation chapters, functioning as links between the Core and Ancillary chapters of the RCPG.

Each of the applicable policies related to the proposed project are identified by number and reproduced below in italics followed by SCAG staff comments regarding the consistency of the project with those policies.

Consistency With Regional Comprehensive Plan and Guide Policies

1. The Growth Management Chapter (GMC) of the Regional Comprehensive Plan contains a number of policies that are particularly applicable to the Sunshine Canyon Landfill Project.

a. *Core Growth Management Policies*

3.01 The population, housing, and jobs forecasts, which are adopted by SCAG's Regional Council and that reflect local plans and policies, shall be used by SCAG in all phases of implementation and review.

SCAG staff comments. As SCAG has designated subregions, the City of Los Angeles part of the Project is situated in the City of Los Angeles subregion, whereas, the part of the project located in unincorporated Los Angeles County is situated in the North Los Angeles County subregion. Implementation of the project would result in the creation of approximately 35 new jobs. This would be a relatively insignificant amount of new jobs and would be within the projected growth for the area. The proposed project would help meet the need for facilities to handle existing and forecasted waste generated within the City of Los Angeles, and nearby cities and unincorporated areas in Los Angeles County. The proposed Los Angeles County Integrated Waste Management Plan and Siting Element, which includes facility needs that the Project is in part designed to meet, and is based on, adopted SCAG growth forecasts. The Draft SEIR contains a discussion of SCAG growth forecast consistency on pages 4-80 and 4-81. The Project is consistent with this core RCPG policy.

3.03 The timing, financing, and location of public facilities, utility systems, and transportation systems shall be used by SCAG to implement the region's growth policies.

SCAG staff comments: Recent studies of solid waste management issues in Southern California, including various City and County of Los Angeles studies referenced in the Draft SEIR, and the recently completed SCAG Solid Waste Task Force Report, have concluded that landfill capacity in the Southern California area has and continues to be a critical issue for local governments. Recycling efforts and the economic downturn during

the past five years have only extended the time to address increased landfill capacity or other waste management alternatives. Siting and expansion of landfills in the urban area has increasingly become more difficult, time consuming and costly. Consequently, the implementation of the proposed project could be considered as an action that would help cities and counties with their long term materials recovery and waste disposal options. This would be consistent with the objectives of the GMC to guide growth in the region and to mitigate its negative impacts. The Draft EIR contains information on phasing and timing, as stated in the above Project Description and on pages 2.-44 and 2.-45. The Project is consistent with this core RCPG policy.

b. *Ancillary Growth Management Policies*

3.05 *Encourage patterns of urban development and land use which reduce costs on infrastructure construction and make better use of existing facilities.*

SCAG staff comments. The Draft EIR, on page 4-80 and in other places throughout the document, acknowledges that Project site has available in-place infrastructure and ancillary facilities that can accommodate additional landfill development. These facilities are contained primarily in the existing active County Landfill site (entrance road, scales, administrative/training building, drainage, gas, waste treatment and water infrastructure) but also portions of the shut down City landfill site (entrance road, nursery, drainage, landfill gas and water infrastructure). Maximizing the use of these facilities helps to reduce the ultimate cost of waste management. The Project is supportive of this ancillary RCPG policy.

3.08 *Encourage subregions to define an economic strategy to maintain the economic vitality of the subregion, including the development and use of marketing programs, and other economic incentives, which support attainment of subregional goals and policies.*

SCAG staff comments. The Draft SEIR on page 4-259 acknowledges that the proposed Project is supportive of two economic development goals in the Los Angeles Citywide General Plan Framework Element (i.e., a physically balanced distribution of land uses that contributes toward and facilitates the City's long-term fiscal and economic viability, conserves natural resources, and provides adequate infrastructure and public resources; and, industrial growth that provides job opportunities for the City's residents and maintains the City's fiscal viability). It also notes that "project implementation would further minimize fuel consumption by developing a landfill in the City's jurisdiction close to wasteshed areas rather than transporting waste to other landfill locations located out-of-County: and, reduced transportation distance provides for lower tipping fees". The Project is supportive of this ancillary RCPG policy.

3.09 *Support local jurisdictions' efforts to minimize the cost of infrastructure and public service delivery, and efforts to seek new sources of funding for development and the provision of*

services.

SCAG staff comments. See SCAG staff comment on RCPG policy 3.05. The Project also includes facilities to handle green and wood waste, and integrates the resultant mulch material into the landfill daily cover program, thus saving costs and helping to keep tipping fees lower. The Project is supportive of this ancillary RCPG policy.

3.10 *Support local jurisdictions' actions to minimize red tape and expedite the permitting process to maintain economic vitality and competitiveness.*

SCAG staff comments. The Draft SEIR, in Section 2.0 (Project Description), acknowledges that the proposed Project builds upon an existing permitted County Landfill which has undergone extensive environmental review. The proposed City/County Landfill will benefit from this experience, and along with new and expanded environmental impact analysis, will help minimize red tape associated with the permitting of an expanded landfill. This in turn, will help to maintain the economic vitality and competitiveness of the combined City/County Landfill. The Project is supportive of this ancillary RCPG policy.

3.12 *Encourage existing or proposed local jurisdictions' programs aimed at designing land uses which encourage the use of transit and thus reduce the need for roadway expansion, reduce the number of auto trips and vehicle miles traveled, and create opportunities for residents to walk and bike.*

SCAG staff comments. The Draft SEIR acknowledges that the Project has a relatively insignificant number of employees and would not be subject to SCAQMD's Rule 2202. It also notes that the Project will result in 440 transfer truck trip ends daily (46% of refuse brought to site will be in transfer trucks) and 1,280 daily trip ends by curbside collection trucks. Mitigation measures are proposed to help encourage use of transfer trucks, direct truck traffic to non-peak hours and increase fees for trucks not carrying full loads. These actions will help reduce vehicle miles traveled by refuse vehicles. The Project is supportive of this ancillary RCPG policy.

3.18 *Encourage planned development in locations least likely to cause adverse environmental impact.*

SCAG staff comments. The Project is designed in a manner which will minimize adverse environmental impacts. The following objectives identified in the Draft SEIR are designed in a manner which will minimize adverse environmental impacts: ensure corporate commitment to meet environmental, health and safety goals, and exceed regulatory standards and requirements during landfilling construction, operation and closure; minimize impacts on air quality within the South Coast Air Basin by providing additional disposal capacity within the Los Angeles region, thereby reducing emissions from transporting

refuse longer distances; and, minimize significant impacts on environmental resources associated with the development of new landfill sites (i.e., proposed sites located within undisturbed canyon areas or remote desert locations) by using areas of the existing inactive landfill and other areas within Sunshine Canyon that are primarily disturbed and that have infrastructure in place to readily accommodate future development.

The mitigation measures included in the Draft EIR have been developed to address any identified adverse environmental impacts. The adequacy of project specific mitigation of impacts should be carefully considered by the City of Los Angeles and the County of Los Angeles. The Project is supportive of this ancillary RCPG policy, as it pertains to the above noted areas.

3.19 *Support policies and actions that preserve open space areas identified in local, state, and federal plans.*

SCAG staff comments. The Draft SEIR acknowledges in Section 4.14 (Public Services) that implementation of the proposed Project will result in the preservation of 987 of open space which will become part of the 8,000 acre Santa Clarita Woodlands State Park. This acreage includes 426 acres in the East Canyon dedication area for open space and recreational purposes, 81 acres dedicated for trail and road purposes, and over 480 acres of land located along the northerly and westerly boundaries of Upper Bee Canyon for wildlife preservation and recreational use. The Draft SEIR notes on page 2-85 that an existing 100 acre open space buffer area is located directly south of the inactive landfill. Within the buffer area, a voluntary tree planting program was initiated by the project proponent and over 11,000 trees have been planted, including over 1,300 coast live oak trees. The Draft SEIR also states on page 4-421 that the developer will fund one community service project within the City per year for 15 years, for such uses as construction of community swimming pools, community parks restoration or development, and community center rehabilitation or development. The Project is supportive of this ancillary RCPG policy.

3.20 *Support the protection of vital resources such as wetlands, groundwater recharge areas, woodlands, production lands, and land containing unique and endangered plants and animals.*

SCAG staff comments. The Draft EIR, in Section 4.4 (Biological Resources), acknowledges that the Project will have major impacts to biota, including: temporary and permanent impacts on biological resources (loss of over 80 acres of Venturan Coastal Sage Scrub, over 31 acres of Coast Live Oak Woodland, two populations of Slender Mariposa Lily and minimal amounts of other sensitive wildlife habitat (i.e., Southern Willow Scrub and Arroyo Willow Scrub). Development of the City/County Landfill will result in the removal of approximately 3 acres of jurisdictional waters, wetlands and riparian habitat. Impacts will also occur to the following sensitive animal species: San Diego Horned Lizard, California Gnatcatcher, Least Bell's Vireo and Western Burrowing Owl. The site does not

function as a wildlife corridor, because of previous landfill disturbance. Mitigation measures are proposed for wildlife habitat, wetlands and sensitive animal species. Additional procedures are proposed to protect migratory bird and raptor breeding sites (nests). Of special note, the existing County Landfill and shut-down City Landfill have maintained a plant materials center or nursery and revegetation program that is of major importance. The Draft SEIR notes that the existing nursery is recognized as one of the largest growers of coast live oak trees in the Southern California region and has initiated a program with Oregon State University and others to study advanced growing techniques for the coast live oaks and big-cone Douglas fir tree species. The adequacy of project specific mitigation of impacts should be carefully considered by the City of Los Angeles and the County of Los Angeles. Assuming the aforementioned mitigation actions are taken and prove effective, the Project would be supportive of this ancillary RCPG policy

3.21 *Encourage the implementation of measures aimed at the preservation and protection of recorded and unrecorded cultural resources and archaeological sites.*

SCAG staff comments. The Draft SEIR acknowledges that no sensitive cultural resources were found to be present on the surface of the site, and that only one non-significant known deposits of prehistoric or historic significance was identified during the records search. Based on this, the Draft SEIR concludes that the proposed Project will have no immediate or direct or indirect impact on cultural resources, and that if cultural resources are identified during the development process, additional studies will be undertaken and corrective actions taken. The project is supportive of this ancillary RCPG policy.

3.22 *Discourage development, or encourage the use of special design requirements, in areas with steep slopes, high fire, flood, and seismic hazards.*

SCAG staff comments. The Draft SEIR acknowledges that onsite grading activities associated with landfill cut-and-cover operations will directly impact development of approximately 451 acres and will result in the excavation of over 10 million cubic yards of material. Grading within the site would balance out over the life of the Project. Excavated soils would be used onsite as the liner foundation layer, liner operations layer, daily cover, intermediate cover, and for the vegetative or erosion control layer of the final cover. Extensive seismic investigation of the site is documented in the Draft SEIR and it states that the Northridge Earthquake produced no significant adverse impacts within the Project area. It concludes that no cumulative impacts for seismic exposure are anticipated. The Draft EIR states on page 4-40 that the landfill will be designed "to withstand the maximum probable earthquake without damage to the foundations or to the structures which control leachate, surface drainage, erosion or gas". It also notes some potential for liquefaction and slope stability (landslides) which can be easily mitigated. Mitigation measures are proposed for all adverse earth resource impacts.

The Draft SEIR documents extensive investigations of the potential risk of upset resulting

from disposal of hazardous materials, vectors, litter, employee safety and site security, human health explosion, airport safety (bird strikes) and electric and magnetic fields (two transmission lines traverse the site). Design features and mitigation measures are proposed to address any potential adverse impacts. The Draft SEIS also acknowledges some potential exists for "hot load" refuse fires, brush fires on-or off site, and subsurface refuse fire. Mitigation measures are proposed to address any adverse impacts.

The Draft SEIR states that a small portion of the project site (i.e., near the bottom of the canyon where the creek flows offsite) is designated within the 100 year floodplain. Sedimentation basins exist or are proposed to hold both predicted sediment load and provide storage capacity necessary to accommodate stormwater flow from the operational County landfill, the upper reaches of Sunshine Canyon and the proposed City/County Landfill.

The adequacy of project specific mitigation of impacts should be carefully considered by the City of Los Angeles and the County of Los Angeles. Assuming the aforementioned actions are taken and prove effective, the Project would be supportive of this ancillary RCPG policy.

3.23 *Encourage mitigation measures that reduce noise in certain locations, measures aimed at preservation of biological and ecological resources, measures that would reduce exposure to seismic hazards, minimize earthquake damage, and to develop emergency response and recovery plans.*

SCAG staff comments. Discussion of mitigation measures for most of these environmental factors is addressed under SCAG policies 3.20 and 3.22. Additionally mitigation measures are proposed to reduce noise below a level of significance. The Project is supportive of this ancillary RCPG policy.

2. The Regional Mobility Chapter (RMC) also has policies, all of which are core, that pertain to the proposed project. This chapter links the goal of sustaining mobility with the goals of fostering economic development, enhancing the environment, reducing energy consumption. promoting transportation-friendly development patterns, and encouraging fair and equitable access to residents affected by socio-economic, geographic and commercial limitations. Among the relevant policies in this chapter are the following:

Regional Streets and Highways Program Policies

4.10 *Potential down-stream congestion impacts from capacity enhancing projects will be studied.*

SCAG staff comments. The Draft SEIR in Chapter 4.13 (Transportation/Circulation) acknowledges on page 4-374 that the Project will add a maximum of 73 peak hour trips in either direction on Interstate 5. Although this volume of trips does not meet the significant impact criteria (150 or more peak hour trips) of the Los Angeles County Congestion

Management Program, the trips will add to a regionally significant AM and PM peak hour congestion problem on Interstate 5. The Draft SEIR on pages 4-346 and 347 notes that 220 transfer trucks and 640 curbside collection vehicles (daily/two-way) would use the facility. The transfer trucks are typically 60 feet long semis (23.5 ton capacity) and the curbside collection vehicles are typically 40 feet long (9 ton capacity). Project traffic distribution data on page 4-348 indicates that of the total 2,260 (daily/two-way) passenger car equivalent (PCE) trips, 10 percent (226 trips) are expected to be distributed north of the project site on I-5 and 45 percent (1,017 trips) are expected to be distributed east on I-5. The total of these I-5 trips (1,243 trips) adds to the continuing congestion problem on I-5. This is particularly significant, given the heavy-duty vehicle contribution that transfer trucks and curbside collection vehicles would add to the I-5 traffic. Although the proposed Project does not address the continuing increased congestion of I-5, it does however acknowledge responsibility to provide turn lane improvements at the I-5 /Rockford Street intersection.

SCAG's comments on the recently proposed Newhall Ranch project included the following: "*The Draft EIR indicates that capacity enhancements will be required on major highways (Interstate 5 and State Route 126), in part, to serve transportation demand generated from the Newhall Ranch Specific Plan. SCAG Regional Travel Forecast Model analysis and input on the regional transportation system from the County Transportation Commissions for the June 1997 SCAG Regional Transportation Plan indicate that for year 2020, most of Interstate 5 south of State Route 126 to State Route 14 is expected to experience delays as a percentage of travel time up to 50 to 70 percent of 1990 conditions. Furthermore, congested speeds on this segment of I-5 will be from 23 to 16 miles per hour in most areas. Greater delays and lower congested speeds south of the I-5/SR 14 intersection to I-405 are anticipated. No provisions for funding the additional improvements, including interchange enhancements, on I-5 have been identified. Funding of I-5 improvements needs to be addressed in the Final EIR, including the Newhall Ranch contribution, if any, to these improvements.* These comments are also applicable to the proposed Sunshine Canyon Landfill Project. Until the funding of congestion mitigation improvements to I-5 and impacted interchanges are resolved to the satisfaction of Caltrans, and LAMTA, the Project can not be found consistent with this core RCPG policy.

4.20 *Expanded transportation system management by local jurisdictions will be encouraged.*

4.23 *TSM activities throughout the region shall be coordinated among jurisdictions.*

SCAG staff comments. The Draft SEIR acknowledges in Section 4.13 (Transportation/Circulation) that the project design and congestion mitigation measures for arterials, impacted intersections and the access roadway into the Sunshine Canyon Landfill site reflect a sensitivity to TSM actions. The recommended automatic traffic surveillance and control (ATSC) signal improvements on San Fernando Road at the Project entrance driveway and at the intersection of San Fernando Road and Balboa Boulevard should be mitigation measures and the landfill developer should contribute their appropriate share to

these TSM improvements. The Project is conditionally consistent with these two core RCPG policies, assuming the aforementioned ATSC actions are taken.

Regional Non-Motorized Transportation Program Policies

4.25 The development of the regional transportation system should include a non-motorized transportation system that provides an effective alternative to auto travel for appropriate trips. The planning and development of transportation projects and systems should incorporate the following, as appropriate:

a " Provision of safe, convenient, and continuous bicycle and pedestrian infrastructure to and throughout areas with existing and potential demand such as activity areas, schools, recreational areas (including those areas served by trails), which will ultimately offer the same or better accessibility provided to the motorized vehicle.

b " Accessibility to and on transit (bus terminals, rail stations, Park-And-Ride lots), where there is demand and where transit boarding time will not be significantly delayed.

c " Maintenance of safe, convenient, and continuous non-motorized travel during and after the construction of transportation and general development projects. Existing bikeways and pedestrian walkways should not be removed without mitigation that is as effective as the original facility.

SCAG staff comments. Draft SEIR acknowledges on pages 4-385 through 387, that the City of Los Angeles proposes to develop a Class II bikeway along San Fernando Road and that this facility could conflict with truck access to the Project. Should this exist, a mitigation measure is proposed to address this conflict. The Draft SEIR acknowledges in Section 4.14 (Public Services) an extensive existing and proposed hiking and equestrian trail system in open space areas surrounding the Project. Consideration should be given in the long range future development of the site for open space purposes, to the inclusion of trail facilities to connect up with adjacent existing or proposed trails. The Project is consistent with this core RCPG policy.

3. The Air Quality Chapter (AQC) core actions that are generally applicable to the Sunshine Canyon Landfill Project are as follows:

5.11 Through the environmental document review process, ensure that plans at all levels of government (regional, air basin, county, subregional and local) consider air quality, land use, transportation and economic relationships to ensure consistency and minimize conflicts.

SCAG staff comments. The Draft SEIR does not acknowledge that the Project incorporates

most recently regional growth forecasts into the transportation and air quality modeling for the Project. We are unable to determine whether regional transportation/air quality impacts would be mitigated. Therefore, based on the information provided in the Draft SEIR, we are unable to find the Project consistent with this core RCPG policy.

4. The Water Quality Chapter (WQC) core recommendations and policy options relate to the two water quality goals:

- *To restore and maintain the chemical, physical and biological integrity of the nation's water (Federal Clean Water Act).*

  SCAG staff comments. The Draft SEIR appropriately acknowledges in Section 4.3 Surface and Groundwater), the manner in which the Project addresses this federal water quality goal.

- *To achieve and maintain water quality objectives that are necessary to protect all beneficial uses of all waters (State Porter-Cologne Water Quality Act).*

  SCAG staff comments. The Draft SEIR appropriately acknowledges in Section 4.3 (Surface and Groundwater) , the manner in which the Project addresses the achievement of State water quality goal.

The Water Quality Chapter's core recommendations and policy options that are particularly applicable to the Sunshine Canyon Landfill Project include the following:

11.02 Encourage "watershed management" programs and strategies, recognizing the primary role of local governments in such efforts.

SCAG staff comments. The Draft EIR references a number of "watershed management" strategies in Section 4.3 (Surface and Groundwater). The adequacy of project mitigation measures should be carefully considered by the City of Los Angeles, Los Angeles County Department of Public Works (Flood Control Division), Los Angeles Regional Water Quality Control Board and U.S. Army Corps of Engineers. The Project is consistent with this core RCPG policy.

11.05 Support regional efforts to identify and cooperatively plan for wetlands to facilitate both sustaining the amount and quality of wetlands in the region and expediting the process for obtaining wetlands permits.

SCAG staff comments. The Draft SEIR in Section 4.4 (Biological Resources) appropriately addresses the preservation and restoration of wetlands. See also previous SCAG staff comments relative to wetlands preservation and restoration under policies 3.18 and 3.20. A variety of project design features and mitigation measures are proposed relative to the

preservation and restoration of riparian ecosystem, including wetlands. The Army Corps of Engineers Section 404 permit, and ancillary wetlands restoration planning requirements will also govern the successful response to this policy. The adequacy of project mitigation measures should be carefully considered by the City of Los Angeles, Los Angeles County Department of Public Works (Flood Control Division), Los Angeles Regional Water Quality Control Board and U.S. Army Corps of Engineers. The Project is consistent with this core RCPG policy.

11.07 Encourage water reclamation throughout the region where it is cost-effective, feasible, and appropriate to reduce reliance on imported water and wastewater discharges. Current administrative impediments to increased use of wastewater should be addressed.

SCAG staff comments. The Draft EIR addresses the possible use of reclaimed groundwater and leachate, both of which are part of a comprehensive ground water management system. This water would be used onsite for landscape, irrigation, dust control, or other non-emergency need. The Project is consistent with this core RCPG policy.

5. The Integrated Solid Waste Management Chapter (ISWM) is non mandated; it is provided for information and advisory purposes. The recommendations in the chapter fulfill the chapter's objectives and do not create new legal mandates for local governments or other regional governmental organizations, like sanitation or waste management districts. The chapter includes the following appropriate policy recommendations:

14.1 Developing recycling industries and self sustaining markets for recycled materials.

SCAG staff comments. The Draft SEIR on page 2-3 acknowledges as a solid waste objective: recover, recycle, and/or reuse waste materials that would be otherwise disposed of at the City/County Landfill by providing public "drop-off", 'buyback". And greenwaste/wood waste recycling areas for local residents. The document also acknowledges on page 4-346 that at least 46 percent of the waste will be transported to the site from transfer stations or MRFs. No provision is referenced in the Draft SEIR which would support the development of recycling industries, except for green/wood waste recycling facilities, that would be developed on a 3 acre site within the Project. Consideration should be given to the development of other recycling industries at the landfill site, either as a part of the on-going landfilling activities or after the landfill is closed. The Project is supportive of this ancillary RCPC policy, as it relates to green/wood waste and the "drop-off" and "buyback" center.

14.3 Economic impacts of increased waste management costs.

SCAG staff comments. The Draft SEIR on page 2-3 acknowledges two key solid waste objectives that pertain this policy: 1) provide cost-effective disposal options for the City, County, and private haulers at a landfill facility located within the region to minimize

transportation costs; and 2) facilitate local and regional efforts directed toward attaining solid waste disposal capacity objectives for the City and County of Los Angeles contained in the California Integrated Waste Management Act of 1989 (AB 939) [and various listed City and County planning documents], and formally executed agreements between the County and the City that identify the need for maximum technically and environmentally feasible expansion of landfill sites. These objectives begin to address the critical issue of increased waste management costs. The Final SEIR should be updated to include policy reference to Chapter 14 (Integrated Solid Waste Management) of the Regional Comprehensive Plan and Guide and consideration of the various recommendations, especially those pertaining to landfills, in the April 1997, SCAG Solid Waste Task Force Report. The City/County Landfill should also consider the inclusion in the Final EIR of a mitigation measure that would include as an important goal to "accept waste only from jurisdictions in compliance with the waste diversion mandates of AB 939". The Project is supportive of this ancillary RCPG policy.

14.4 Promote new technologies.

SCAG staff comments. The Draft SEIR acknowledges that the Project will incorporate some new technology features in the design and operation of the City/County Landfill. These include the state-of-the-art Plant Materials Center, bottom composite and side-slope liner systems (including a more superior alternative side-slope liner) and an automatic tracking system to monitor and account for all incoming waste. In the evaluation of project alternatives, the Draft SEIR considered and rejected various waste management technologies and strategies, including: source reduction, recycling, composting, waste-to-energy, and the use of alternative daily cover materials. This analysis is included in Section 5.9 (Waste Management Technologies and Strategies). The Draft SEIR on page 1-14 concludes that "solid waste transformation technologies such as co-composting, pyrolysis, landfill mining, and high-volume shredding are considered speculative, and these technologies are not feasible alternatives to the proposed Project". Although the Draft SEIR acknowledges alternative waste management technologies, it does not address specific technologies in a comprehensive manner. The Project is partially supportive of this ancillary RCPG policy as it relates to the stated new technology project features, but not supportive of the policy as it relates to alternative waste management technologies.

14.5 Facilitating regional dialogue on intercounty waste disposal projects.

SCAG staff comments. The Draft SEIR presents a clear discussion of various alternative waste disposal facilities in Section 5.0 (Alternatives). The information presented is helpful in facilitating the regional dialogue on intercounty waste disposal projects. Furthermore, the Draft SEIR presents a case to support the selection of the proposed Project over the various alternatives noted in the Project Description. The Project is supportive of this ancillary RCPG policy.

Consistency with the 208 Plan for the South Coast Planning Area

Under Section 208 of the Clean Water Act, SCAG prepared the Areawide Waste Treatment Management Plan for the South Coast Planning Area in 1979 and made amendments to the plan in 1981. SCAG has been precluded from updating the plan due to lack of federal or state funds. The State Water Resource Control Board has not funded SCAG's updating of the 208 Plan for the South Coast Planning area. The growth forecasts on which the 208 plan was based and many of the plan's policies and actions are dated.

SCAG staff comments: As previously noted, the Project is consistent with SCAG's adopted population forecasts. These forecasts, however, have not been incorporated into the 208 Plan for the South Coast Planning Area. Furthermore, the various Residual Waste Management (especially Sanitary Landfill) policies and actions in the 208 Plan are dated SCAG is unable to make a finding that the Project is consistent with the 208 Plan for the South Coast Planning Area.

Conclusions and Recommendations:

(1) As noted in the staff comments, the proposed Draft Supplemental Environmental Impact Report for the Sunshine Canyon Landfill is consistent with or supports many of the core and ancillary policies in the Regional Comprehensive Plan and Guide Until the funding of congestion mitigation improvements to Interstate 5 and impacted interchanges are resolved to the satisfaction of Caltrans and LAMTA, the Project can not be found consistent with core policy 4.10. The Project is conditionally consistent with core policies 4.20 and 4.23. The Project is partially supportive of ancillary policy 14.4, but not supportive of the manner in which it addresses alternative waste management technologies. Furthermore, based on insufficient information in the Draft Supplemental Environmental Impact Report, we are unable to determine consistency with core policy 5.11.

(2) For the reasons stated herein, SCAG is unable to make a finding tht the Project is consistent with the 208 Plan for the South Coast Planning Area.

(3) All mitigation measures associated with the project should be monitored in accordance with AB 3180 requirements and reported to SCAG through the Annual Reasonable Further Progress Reports.

SOUTHERN CALIFORNIA ASSOCIATION OF GOVERNMENTS

Roles and Authorities

THE SOUTHERN CALIFORNIA ASSOCIATION OF GOVERNMENTS is a *Joint Powers Agency* established under California Government Code Section 6502 et seq. Under federal and state law, the Association is designated as a Council of Governments (COG), a Regional Transportation Planning Agency (RTPA), and a Metropolitan Planning Organization (MPO). Among its other mandated roles and responsibilities, the Association is:

! Designated by the federal government as the Region's *Metropolitan Planning Organization* and mandated to maintain a continuing, cooperative, and comprehensive transportation planning process resulting in a Regional Transportation Plan and a Regional Transportation Improvement Program pursuant to 23 U.S.C. '134(g)-(h), 49 U.S.C. '1607(f)-(g) et seq., 23 C.F.R. '450, and 49 C.F.R. '613. The Association is also the designated *Regional Transportation Planning Agency*, and as such is responsible for both preparation of the Regional Transportation Plan (RTP) and Regional Transportation Improvement Program (RTIP) under California Government Code Section 65080.

! Responsible for developing the demographic projections and the integrated land use, housing, employment, and transportation programs, measures, and strategies portions of the *South Coast Air Quality Management Plan*, pursuant to California Health and Safety Code Section 40460(b)-(c). The Association is also designated under 42 U.S.C. '7504(a) as a *Co-Lead Agency* for air quality planning for the Central Coast and Southeast Desert Air Basin District.

! Responsible under the Federal Clean Air Act for determining *Conformity* of Projects, Plans and Programs to the State Implementation Plan, pursuant to 42 U.S.C. '7506.

! Responsible, pursuant to California Government Code Section 65089.2, for *reviewing all Congestion Management Plans (CMPs) for consistency with regional transportation plans* required by Section 65080 of the Government Code. The Association must also evaluate the consistency and compatibility of such programs within the region.

! The authorized regional agency for *Inter-Governmental Review* of Programs proposed for federal financial assistance and direct development activities, pursuant to Presidential Executive Order 12,372 (replacing A-95 Review).

! Responsible for reviewing, pursuant to Sections 15125(b) and 15206 of the CEQA Guidelines, *Environmental Impact Reports* of projects of regional significance for consistency with regional plans.

! The authorized *Areawide Waste Treatment Management Planning Agency*, pursuant to 33 U.S.C. '1288(a)(2) (Section 208 of the Federal Water Pollution Control Act) .

! Responsible for preparation of the *Regional Housing Needs Assessment*, pursuant to California Government Code Section 65584(a).

! Responsible (along with the San Diego Association of Governments and the Santa Barbara County/Cities Area Planning Council) for preparing the *Southern California Hazardous Waste Management Plan* pursuant to California Health and Safety Code Section 25135.3.

RE: Comments on the Draft Subsequent Environmental Impact Report for the Sunshine Canyon Landfill Project - SCAG No. I9700400

Dear Mr. Plafkin:

This is a follow-up letter to one dated September 4, 1997. At that time I invited you to attend our next meeting of the SCAG Standing Committee on Implementation (SCI), held October 9. Since then the SCAG Regional Council has called for a General Assembly to be held on October 9 instead of the regular committee meetings.

The item on the **Draft Subsequent Environmental Impact Report for the Sunshine Canyon Landfill Project** will be heard at the November 6, 1997 SCI meeting to be held at the SCAG office in Los Angeles, starting at 11:15 a.m. 9

SCAG staff comments to the SCI differ somewhat from those we originally sent you. They reflect a new agency position on projects impacted by recent 208 Plan consistency and conformity discussions with the State California Water Resources Control Board. A copy of these comments is enclosed.

If you have any questions please contact Bill Boyd at (213) 236-1960 for further information concerning this meeting which you are invited to attend.

Sincerely,

J. DAVID STEIN
Manager, Performance Assessment
and Implementation

JDS:lj

MEMORANDUM

TO: Standing Committee on Implementation

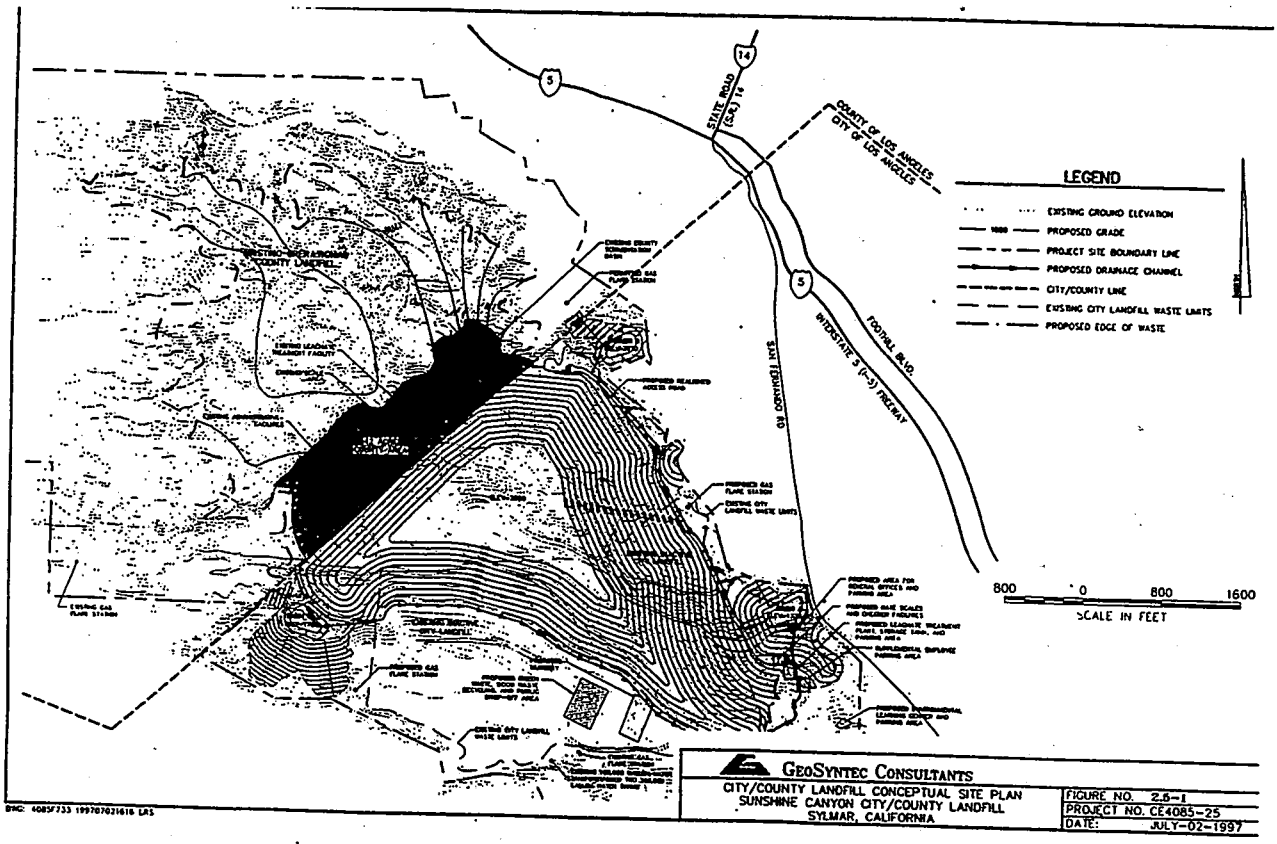
FROM: Bill Boyd, IGR Analyst, Telephone (213) 236-1960 -- boyd@scag.ca.gov

SUBJECT: Sunshine Canyon Landfill Draft Subsequent Environmental Impact Report

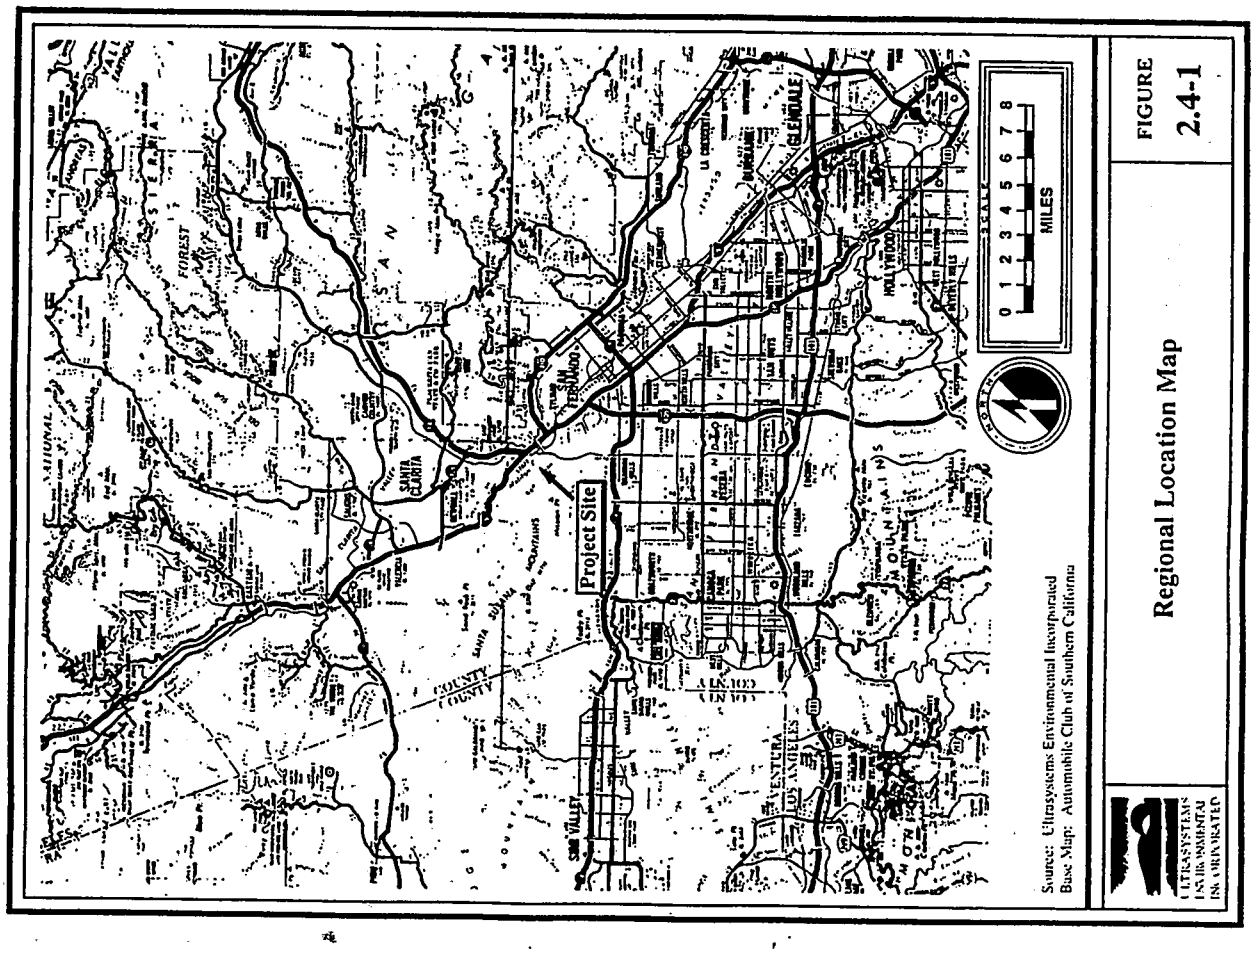
DATE: November 6, 1997

==========

Project Description



The proposed Project consists of the development , operation, maintenance, and monitoring of a Class III, nonhazardous solid waste landfill (City/County Landfill). The Project site is located in Sunshine Canyon, due south of the intersection of Interstate 5 and the State Route 14 junction. [See Figure 2.4-1] It is accessible off of San Fernando Road. A portion of the proposed City/County Landfill footprint is located on approximately 194 acres within the City of Los Angeles (City). In order to facilitate the design of the proposed project, an area of approximately 42 acres in the County of Los Angeles (County) would be developed. This acreage would be engineered to ultimately connect, both vertically and horizontally, to the proposed landfill in the City and the operational County Landfill (existing landfill footprint of approximately 215 acres). [See Figure 2.5-1]



Initially, these landfill areas would be operated separately and provide an average daily capacity of 5,000 tons per day (tpd) in the City and 6,000 tpd in the County. Within 18 to 24 months, following the commencement of landfilling operations in the City, landfilling operations would be combined into a single landfill operation and at one working face area. This would allow for an average waste intake rate of 11,000 tpd. This landfill footprint configuration would ultimately encompass approximately 451 acres and result in a net disposal capacity of 90 million tons. This footprint includes the operational County Landfill with an approved permitted capacity of 17 million tons.

The landfill would be operated 16 hours per day (i.e., 5:00 a.m. to 9:00 p.m., Monday through Saturday), 6 days per week, two shifts per day. At maximum operation, the landfill would employ 35 people, in addition to the 52 employees currently employed at the County Landfill.

The Project also consists of developing and operating numerous ancillary areas and facilities to support landfilling operations at the City/County Landfill. These would include: administrative offices, caretaker trailer, lunchroom/locker building, employee parking, environmental learning center, green waste/wood waste recycling area, plant materials center (or nursery) , scale house and check-in facility. The following environmental protection and control systems would be installed during the development of the City/County Landfill: subdrain system, foundation layer, liner system, leachate collection and removal system, surface water drainage controls, sedimentation basin, landfill gas collection and flaring system, and groundwater protection.

In order to eliminate potential environmental impacts, the proposed Project includes a number of disposal site control measures or features, including: litter prevention and control, dust abatement , vector and bird control, noise control, odor control, fire control, hazardous waste exclusion and

visual/landscaping buffer areas. In addition to these control measures or features, basic safety features would be provided, such as emergency shutoffs for all equipment, interlocking systems, for safe, coordinated startup and shutoff of connected equipment systems, protective covers for all exposed moving equipment, and adequate on-site safety features.

It is anticipated that a majority of the incoming wastes disposed of at the landfill would be generated in the City, surrounding communities proximate to the project site, and unincorporated areas in the County. It is also expected that refuse may be generated by other jurisdictions within the Los Angeles region. The primary form of refuse transport to the site would be transfer trucks from existing transfer stations/MRFs that are either owned, operated , or leased by the project proponent (Browning-Ferris Industries of California, Inc.). In addition to that traffic flow, wastes would be transported by municipal and private refuse-hauling vehicles collecting solid waste from various incorporated jurisdictions and unincorporated communities.

Alternatives to the proposed project include:

- No Project,
- Reduced Volume,
- Immediate Combined City/County Landfill Operations,
- Potential/Proposed Landfill Sites in Los Angeles County,
- Out-of- County Landfill Sites,
- Waste Management Technologies and Strategies,
- Remote Landfill Facilities In-State/Out-of-State

Key Issue

o Is the Project consistent with the Regional Comprehensive Plan and Guide?

Consistency With Regional Comprehensive Plan and Guide Policies

1. The Growth Management Chapter (GMC) of the Regional Comprehensive Plan contains a number of policies that are particularly applicable to this Project.

a. *Core Growth Management Policies*

3.01 The population, housing, and jobs forecasts, which are adopted by SCAG's Regional Council and that reflect local plans and policies, shall be used by SCAG in all phases of implementation and review.

SCAG staff comments. As SCAG has designated subregions, the City of Los Angeles part of the Project is situated in the City of Los Angeles subregion, whereas, the part of the project located in unincorporated Los Angeles County is situated in the North Los Angeles County subregion. Implementation of the project would result in the creation of approximately 35 new jobs. This would be a relatively insignificant amount of new jobs and would be within the projected growth for the area. The proposed project would help meet the need for facilities to handle existing and forecasted waste generated within the City of Los Angeles, and nearby cities and unincorporated areas in Los Angeles County The proposed Los Angeles County Integrated Waste Management Plan and Siting Element, which includes facility needs that the Project is in part designed to meet, and is based on, adopted SCAG growth forecasts. The Draft SEIR contains a discussion of SCAG growth forecast consistency on pages 4-80 and 4-81. The Project is consistent with this core RCPG policy. 10

3.03 The timing, financing, and location of public facilities, utility systems, and transportation systems shall be used by SCAG to implement the region's growth policies.

SCAG staff comments: Recent studies of solid waste management issues in Southern California, including various City and County of Los Angeles studies referenced in the Draft SEIR, and the recently completed SCAG Solid Waste Task Force Report, have concluded that landfill capacity in the Southern California area has and continues to be a critical issue for local governments. Recycling efforts and the economic downturn during the past five years have only extended the time to address increased landfill capacity or other waste management alternatives. Siting and expansion of landfills in the urban area has increasingly become more difficult, time consuming and costly. Consequently, the implementation of the proposed project could be considered as an action that would help cities and counties with their long term materials recovery and waste disposal options. This would be consistent with the objectives of the GMC to guide growth in the region and to mitigate its negative impacts. The Draft EIR contains information on phasing and timing, as stated in the above Project Description and on pages 2.-44 and 2.-45. The Project is consistent with this core RCPG policy. 11

b. *Ancillary Growth Management Policies*

3.05 Encourage patterns of urban development and land use which reduce costs on infrastructure construction and make better use of existing facilities.

SCAG staff comments. The Draft EIR, on page 4-80 and in other places throughout the document, acknowledges that Project site has available in-place infrastructure and ancillary facilities that can accommodate additional landfill development. These facilities are contained primarily in the existing active County Landfill site (entrance road, scales, administrative/training building, drainage, gas, waste treatment and water infrastructure) but also portions of the shut down City landfill site (entrance road, nursery, drainage, landfill gas and water infrastructure). Maximizing the use of these facilities helps to reduce the ultimate cost of waste management. The Project is supportive of this ancillary RCPG policy. 12

3.08 Encourage subregions to define an economic strategy to maintain the economic vitality of the subregion, including the development and use of marketing programs, and other economic incentives, which support attainment of subregional goals and policies.

SCAG staff comments. The Draft SEIR on page 4-259 acknowledges that the proposed Project is supportive of two economic development goals in the Los Angeles Citywide General Plan Framework Element (i.e., a physically balanced distribution of land uses that contributes toward and facilitates the City's long-term fiscal and economic viability, conserves natural resources, and provides adequate infrastructure and public resources; and, industrial growth that provides job opportunities for the City's residents and maintains the City's fiscal viability). It also notes that "project implementation would further minimize fuel consumption by developing a landfill in the City's jurisdiction close to wasteshed areas rather than transporting waste to other landfill locations located out-of-County: and, reduced transportation distance provides for lower tipping fees". The Project is supportive of this ancillary RCPG policy. 13

3.09 Support local jurisdictions' efforts to minimize the cost of infrastructure and public service delivery, and efforts to seek new sources of funding for development and the provision of 14

services.

SCAG staff comments. See SCAG staff comment on RCPG policy 3.05. The Project also includes facilities to handle green and wood waste, and integrates the resultant mulch material into the landfill daily cover program, thus saving costs and helping to keep tipping fees lower. The Project is supportive of this ancillary RCPG policy.

3.10 *Support local jurisdictions' actions to minimize red tape and expedite the permitting process to maintain economic vitality and competitiveness.*

SCAG staff comments. The Draft SEIR, in Section 2.0 (Project Description), acknowledges that the proposed Project builds upon an existing permitted County Landfill which has undergone extensive environmental review. The proposed City/County Landfill will benefit from this experience, and along with new and expanded environmental impact analysis, will help minimize red tape associated with the permitting of an expanded landfill. This in turn, will help to maintain the economic vitality and competitiveness of the combined City/County Landfill. The Project is supportive of this ancillary RCPG policy. 15

3.12 *Encourage existing or proposed local jurisdictions' programs aimed at designing land uses which encourage the use of transit and thus reduce the need for roadway expansion, reduce the number of auto trips and vehicle miles traveled, and create opportunities for residents to walk and bike.*

SCAG staff comments. The Draft SEIR acknowledges that the Project has a relatively insignificant number of employees and would not be subject to SCAQMD's Rule 2202. It also notes that the Project will result in 440 transfer truck trip ends daily (46% of refuse brought to site will be in transfer trucks) and 1,280 daily trip ends by curbside collection trucks. Mitigation measures are proposed to help encourage use of transfer trucks, direct truck traffic to non-peak hours and increase fees for trucks not carrying full loads. These actions will help reduce vehicle miles traveled by refuse vehicles. The Project is supportive of this ancillary RCPG policy. 16

3.18 *Encourage planned development in locations least likely to cause adverse environmental impact.*

SCAG staff comments. The Project is designed in a manner which will minimize adverse environmental impacts. The following objectives identified in the Draft SEIR are designed in a manner which will minimize adverse environmental impacts: ensure corporate commitment to meet environmental, health and safety goals, and exceed regulatory standards and requirements during landfilling construction, operation and closure; minimize impacts on air quality within the South Coast Air Basin by providing additional disposal capacity within the Los Angeles region, thereby reducing emissions from transporting refuse longer distances; and, minimize significant impacts on environmental resources associated with the development of new landfill sites (i.e., proposed sites located within undisturbed canyon areas or remote desert locations) by using areas of the existing inactive landfill and other areas within Sunshine Canyon that are primarily disturbed and that have infrastructure in place to readily accommodate future development. 17

The mitigation measures included in the Draft EIR have been developed to address any identified adverse environmental impacts. The adequacy of project specific mitigation of impacts should be carefully considered by the City of Los Angeles and the County of Los Angeles. The Project is supportive of this ancillary RCPG policy, as it pertains to the above noted areas.

3.19 *Support policies and actions that preserve open space areas identified in local, state, and federal plans.*

SCAG staff comments. The Draft SEIR acknowledges in Section 4.14 (Public Services) that implementation of the proposed Project will result in the preservation of 987 of open space which will become part of the 8,000 acre Santa Clarita Woodlands State Park. This acreage includes 426 acres in the East Canyon dedication area for open space and recreational purposes, 81 acres dedicated for trail and road purposes, and over 480 acres of land located along the northerly and westerly boundaries of Upper Bee Canyon for wildlife preservation and recreational use. The Draft SEIR notes on page 2-85 that an existing 100 acre open space buffer area is located directly south of the inactive landfill. Within the buffer area, a voluntary tree planting program was initiated by the project proponent and over 11,000 trees have been planted, including over 1,300 coast live oak trees. The Draft SEIR also states on page 4-421 that the developer will fund one community service project within the City per year for 15 years, for such uses as construction of community swimming pools, community parks restoration or development, and community center rehabilitation or development. The Project is supportive of this ancillary RCPG policy. 18

3.20 *Support the protection of vital resources such as wetlands, groundwater recharge areas, woodlands, production lands, and land containing unique and endangered plants and animals.*

SCAG staff comments. The Draft EIR, in Section 4.4 (Biological Resources), acknowledges that the Project will have major impacts to biota, including: temporary and permanent impacts on biological resources (loss of over 80 acres of Venturan Coastal Sage Scrub, over 31 acres of Coast Live Oak Woodland, two populations of Slender Mariposa Lily and minimal amounts of other sensitive wildlife habitat (i.e., Southern Willow Scrub and Arroyo Willow Scrub). Development of the City/County Landfill will result in the removal of approximately 3 acres of jurisdictional waters, wetlands and riparian habitat. Impacts will also occur to the following sensitive animal species: San Diego Horned Lizard, California Gnatcatcher, Least Bell's Vireo and Western Burrowing Owl. The site does not function as a wildlife corridor, because of previous landfill disturbance. Mitigation measures are proposed for wildlife habitat, wetlands and sensitive animal species. Additional procedures are proposed to protect migratory bird and raptor breeding sites (nests). Of special note, the existing County Landfill and shut-down City Landfill have maintained a plant materials center or nursery and revegetation program that is of major importance. The Draft SEIR notes that the existing nursery is recognized as one of the largest growers of coast live oak trees in the Southern California region and has initiated a program with Oregon State University and others to study advanced growing techniques for the coast live oaks and big-cone Douglas fir tree species. The adequacy of project specific mitigation of impacts should be carefully considered by the City of Los Angeles and the County of Los Angeles. Assuming the aforementioned mitigation actions are taken and prove effective, the Project would be supportive of this ancillary RCPG policy. 19

3.21 *Encourage the implementation of measures aimed at the preservation and protection of recorded and unrecorded cultural resources and archaeological sites.* 20

SCAG staff comments. The Draft SEIR acknowledges that no sensitive cultural resources were found to be present on the surface of the site, and that only one non-significant known deposits of prehistoric or historic significance was identified during the records search.

Based on this, the Draft SEIR concludes that the proposed Project will have no immediate or direct or indirect impact on cultural resources, and that if cultural resources are identified during the development process, additional studies will be undertaken and corrective actions taken. The project is supportive of this ancillary RCPG policy.

3.22 *Discourage development, or encourage the use of special design requirements, in areas with steep slopes, high fire, flood, and seismic hazards.*

SCAG staff comments. The Draft SEIR acknowledges that onsite grading activities associated with landfill cut-and-cover operations will directly impact development of approximately 451 acres and will result in the excavation of over 10 million cubic yards of material. Grading within the site would balance out over the life of the Project. Excavated soils would be used onsite as the liner foundation layer, liner operations layer, daily cover, intermediate cover, and for the vegetative or erosion control layer of the final cover. Extensive seismic investigation of the site is documented in the Draft SEIR and it states that the Northridge Earthquake produced no significant adverse impacts within the Project area. It concludes that no cumulative impacts for seismic exposure are anticipated. The Draft EIR states on page 4-40 that the landfill will be designed "to withstand the maximum probable earthquake without damage to the foundations or to the structures which control leachate, surface drainage, erosion or gas". It also notes some potential for liquefaction and slope stability (landslides) which can be easily mitigated. Mitigation measures are proposed for all adverse earth resource impacts. 21

The Draft SEIR documents extensive investigations of the potential risk of upset resulting from disposal of hazardous materials, vectors, litter, employee safety and site security, human health explosion, airport safety (bird strikes) and electric and magnetic fields (two transmission lines traverse the site). Design features and mitigation measures are proposed to address any potential adverse impacts. 22 The Draft SEIS also acknowledges some potential exists for "hot load" refuse fires, brush fires on-or off site, and subsurface refuse fire. Mitigation measures are proposed to address any adverse impacts. 23

The Draft SEIR states that a small portion of the project site (i.e., near the bottom of the canyon where the creek flows offsite) is designated within the 100 year floodplain. Sedimentation basins exist or are proposed to hold both predicted sediment load and provide storage capacity necessary to accommodate stormwater flow from the operational County landfill, the upper reaches of Sunshine Canyon and the proposed City/County Landfill. 24

The adequacy of project specific mitigation of impacts should be carefully considered by the City of Los Angeles and the County of Los Angeles. Assuming the aforementioned actions are taken and prove effective, the Project would be supportive of this ancillary RCPG policy.

3.23 *Encourage mitigation measures that reduce noise in certain locations, measures aimed at preservation of biological and ecological resources, measures that would reduce exposure to seismic hazards, minimize earthquake damage, and to develop emergency response and recovery plans.* 25

SCAG staff comments. Discussion of mitigation measures for most of these environmental factors is addressed under SCAG policies 3.20 and 3.22. Additionally mitigation measures are proposed to reduce noise below a level of significance. The Project is supportive of this ancillary RCPG policy.

2. The Regional Mobility Chapter (RMC) also has policies, all of which are core, that pertain to the proposed project. This chapter links the goal of sustaining mobility with the goals of fostering economic development, enhancing the environment, reducing energy consumption. promoting transportation-friendly development patterns, and encouraging fair and equitable access to residents affected by socio-economic, geographic and commercial limitations. Among the relevant policies in this chapter are the following:

Regional Streets and Highways Program Policies

4.10 *Potential down-stream congestion impacts from capacity enhancing projects will be studied.*

SCAG staff comments. The Draft SEIR in Chapter 4.13 (Transportation/Circulation) acknowledges on page 4-374 that the Project will add a maximum of 73 peak hour trips in either direction on Interstate 5. Although this volume of trips does not meet the significant impact criteria (150 or more peak hour trips) of the Los Angeles County Congestion Management Program, the trips will add to a regionally significant AM and PM peak hour congestion problem on Interstate 5. The Draft SEIR on pages 4-346 and 347 notes that 220 transfer trucks and 640 curbside collection vehicles (daily/two-way) would use the facility. The transfer trucks are typically 60 feet long semis (23.5 ton capacity) and the curbside collection vehicles are typically 40 feet long (9 ton capacity). Project traffic distribution data on page 4-348 indicates that of the total 2,260 (daily/two-way) passenger car equivalent (PCE) trips, 10 percent (226 trips) are expected to be distributed north of the project site on I-5 and 45 percent (1,017 trips) are expected to be distributed east on I-5. The total of these I-5 trips (1,243 trips) adds to the continuing congestion problem on I-5. This is particularly significant, given the heavy-duty vehicle contribution that transfer trucks and curbside collection vehicles would add to the I-5 traffic. Although the proposed Project does not address the continuing increased congestion of I-5, it does however acknowledge responsibility to provide turn lane improvements at the I-5 /Rockford Street intersection. 26

SCAG's comments on the recently proposed Newhall Ranch project included the following: *"The Draft EIR indicates that capacity enhancements will be required on major highways (Interstate 5 and State Route 126), in part, to serve transportation demand generated from the Newhall Ranch Specific Plan. SCAG Regional Travel Forecast Model analysis and input on the regional transportation system from the County Transportation Commissions for the June 1997 SCAG Regional Transportation Plan indicate that for year 2020, most of Interstate 5 south of State Route 126 to State Route 14 is expected to experience delays as a percentage of travel time up to 50 to 70 percent of 1990 conditions. Furthermore, congested speeds on this segment of I-5 will be from 23 to 16 miles per hour in most areas. Greater delays and lower congested speeds south of the I-5/SR 14 intersection to I-405 are anticipated. No provisions for funding the additional improvements, including interchange enhancements, on I-5 have been identified. Funding of I-5 improvements needs to be addressed in the Final EIR, including the Newhall Ranch contribution, if any, to these improvements.* These comments are also applicable to the proposed Sunshine Canyon Landfill Project. Until the funding of congestion mitigation improvements to I-5 and impacted interchanges are resolved to the satisfaction of Caltrans, and LAMTA, the Project can not be found consistent with this core RCPG policy. 27

4.20 *Expanded transportation system management by local jurisdictions will be encouraged.* 28

4.23 *TSM activities throughout the region shall be coordinated among jurisdictions.*

SCAG staff comments. The Draft SEIR acknowledges in Section 4.13

(Transportation/Circulation) that the project design and congestion mitigation measures for arterials, impacted intersections and the access roadway into the Sunshine Canyon Landfill site reflect a sensitivity to TSM actions. The recommended automatic traffic surveillance and control (ATSC) signal improvements on San Fernando Road at the Project entrance driveway and at the intersection of San Fernando Road and Balboa Boulevard should be mitigation measures and the landfill developer should contribute their appropriate share to these TSM improvements. The Project is conditionally consistent with these two core RCPG policies, assuming the aforementioned ATSC actions are taken.

Regional Non-Motorized Transportation Program Policies

4.25 The development of the regional transportation system should include a non-motorized transportation system that provides an effective alternative to auto travel for appropriate trips. The planning and development of transportation projects and systems should incorporate the following, as appropriate:

- *a o Provision of safe, convenient, and continuous bicycle and pedestrian infrastructure to and throughout areas with existing and potential demand such as activity areas, schools, recreational areas (including those areas served by trails), which will ultimately offer the same or better accessibility provided to the motorized vehicle.*
- *b o Accessibility to and on transit (bus terminals, rail stations, Park-And-Ride lots), where there is demand and where transit boarding time will not be significantly delayed.* 29
- *c o Maintenance of safe, convenient, and continuous non-motorized travel during and after the construction of transportation and general development projects. Existing bikeways and pedestrian walkways should not be removed without mitigation that is as effective as the original facility.*

SCAG staff comments. Draft SEIR acknowledges on pages 4-385 through 387, that the City of Los Angeles proposes to develop a Class II bikeway along San Fernando Road and that this facility could conflict with truck access to the Project. Should this exist, a mitigation measure is proposed to address this conflict. The Draft SEIR acknowledges in Section 4.14 (Public Services) an extensive existing and proposed hiking and equestrian trail system in open space areas surrounding the Project. Consideration should be given in the long range future development of the site for open space purposes, to the inclusion of trail facilities to connect up with adjacent existing or proposed trails. The Project is consistent with this core RCPG policy.

3. The Air Quality Chapter (AQC) core actions that are generally applicable to the Sunshine Canyon Landfill Project are as follows:

5.11 Through the environmental document review process, ensure that plans at all levels of government (regional, air basin, county, subregional and local) consider air quality, land use, transportation and economic relationships to ensure consistency and minimize conflicts. 30

SCAG staff comments. The Draft SEIR does not acknowledge that the Project incorporates most recently regional growth forecasts into the transportation and air quality modeling for the Project. We are unable to determine whether regional transportation/air quality impacts would be mitigated. Therefore, based on the information provided in the Draft SEIR, we are unable to find the Project consistent with this core RCPG policy.

4. The Water Quality Chapter (WQC) core recommendations and policy options relate to the two water quality goals:

- *To restore and maintain the chemical, physical and biological integrity of the nation's water (Federal Clean Water Act).* 31

SCAG staff comments. The Draft SEIR appropriately acknowledges in Section 4.3 Surface and Groundwater), the manner in which the Project addresses this federal water quality goal.

- *To achieve and maintain water quality objectives that are necessary to protect all beneficial uses of all waters (State Porter-Cologne Water Quality Act).* 32

SCAG staff comments. The Draft SEIR appropriately acknowledges in Section 4.3 (Surface and Groundwater) , the manner in which the Project addresses the achievement of State water quality goal.

The Water Quality Chapter's core recommendations and policy options that are particularly applicable to the Sunshine Canyon Landfill Project include the following:

11.02 Encourage "watershed management" programs and strategies, recognizing the primary role of local governments in such efforts. 33

SCAG staff comments. The Draft EIR references a number of "watershed management" strategies in Section 4.3 (Surface and Groundwater). The adequacy of project mitigation measures should be carefully considered by the City of Los Angeles, Los Angeles County Department of Public Works (Flood Control Division), Los Angeles Regional Water Quality Control Board and U.S. Army Corps of Engineers. The Project is consistent with this core RCPG policy.

11.05 Support regional efforts to identify and cooperatively plan for wetlands to facilitate both sustaining the amount and quality of wetlands in the region and expediting the process for obtaining wetlands permits.

SCAG staff comments. The Draft SEIR in Section 4.4 (Biological Resources) appropriately addresses the preservation and restoration of wetlands. See also previous SCAG staff comments relative to wetlands preservation and restoration under policies 3.18 and 3.20. A variety of project design features and mitigation measures are proposed relative to the preservation and restoration of riparian ecosystem, including wetlands. The Army Corps of Engineers Section 404 permit, and ancillary wetlands restoration planning requirements will also govern the successful response to this policy. The adequacy of project mitigation measures should be carefully considered by the City of Los Angeles, Los Angeles County Department of Public Works (Flood Control Division), Los Angeles Regional Water Quality Control Board and U.S. Army Corps of Engineers. The Project is consistent with this core RCPG policy. 34

11.07 Encourage water reclamation throughout the region where it is cost-effective, feasible, and appropriate to reduce reliance on imported water and wastewater discharges. Current administrative impediments to increased use of wastewater should be addressed. 35

SCAG staff comments. The Draft EIR addresses the possible use of reclaimed groundwater and leachate, both of which are part of a comprehensive ground water management system. This water would be used onsite for landscape, irrigation, dust control, or other non-emergency need. The Project is consistent with this core RCPG policy.

5. The Integrated Solid Waste Management Chapter (ISWM) is non mandated; it is provided for information and advisory purposes. The recommendations in the chapter fulfill the chapter's objectives and do not create new legal mandates for local governments or other regional governmental organizations, like sanitation or waste management districts. The chapter includes the following appropriate policy recommendations: 36

14.1 *Developing recycling industries and self sustaining markets for recycled materials.*

SCAG staff comments. The Draft SEIR on page 2-3 acknowledges as a solid waste objective: recover, recycle, and/or reuse waste materials that would be otherwise disposed of at the City/County Landfill by providing public "drop-off", 'buyback". And greenwaste/wood waste recycling areas for local residents. The document also acknowledges on page 4-346 that at least 46 percent of the waste will be transported to the site from transfer stations or MRFs. No provision is referenced in the Draft SEIR which would support the development of recycling industries, except for green/wood waste recycling facilities, that would be developed on a 3 acre site within the Project. Consideration should be given to the development of other recycling industries at the landfill site, either as a part of the on-going landfilling activities or after the landfill is closed. The Project is supportive of this ancillary RCPC policy, as it relates to green/wood waste and the "drop-off" and "buyback" center. 37

14.3 *Economic impacts of increased waste management costs.*

SCAG staff comments. The Draft SEIR on page 2-3 acknowledges two key solid waste objectives that pertain this policy: 1) provide cost-effective disposal options for the City, County, and private haulers at a landfill facility located within the region to minimize transportation costs; and 2) facilitate local and regional efforts directed toward attaining solid waste disposal capacity objectives for the City and County of Los Angeles contained in the California Integrated Waste Management Act of 1989 (AB 939) [and various listed City and County planning documents], and formally executed agreements between the County and the City that identify the need for maximum technically and environmentally feasible expansion of landfill sites. These objectives begin to address the critical issue of increased waste management costs. The Final SEIR should be updated to include policy reference to Chapter 14 (Integrated Solid Waste Management) of the Regional Comprehensive Plan and Guide and consideration of the various recommendations, especially those pertaining to landfills, in the April 1997, SCAG Solid Waste Task Force Report. The City/County Landfill should also consider the inclusion in the Final EIR of a mitigation measure that would include as an important goal to "accept waste only from jurisdictions in compliance with the waste diversion mandates of AB 939". The Project is supportive of this ancillary RCPG policy. 38

14.4 *Promote new technologies.*

SCAG staff comments. The Draft SEIR acknowledges that the Project will incorporate some new technology features in the design and operation of the City/County Landfill. These include the state-of-the-art Plant Materials Center, bottom composite and side-slope liner systems (including a more superior alternative side-slope liner) and an automatic tracking system to monitor and account for all incoming waste. In the evaluation of project alternatives, the Draft SEIR considered and rejected various waste management technologies and strategies, including: source reduction, recycling, composting, waste-to-energy, and the use of alternative daily cover materials. This analysis is included in Section 5.9 (Waste Management Technologies and Strategies). The Draft SEIR on page 1-14 concludes that "solid waste transformation technologies such as co-composting, pyrolysis, landfill mining, and high-volume shredding are considered speculative, and these technologies are not feasible alternatives to the proposed Project". Although the Draft SEIR acknowledges alternative waste management technologies, it does not address specific technologies in a comprehensive manner. The Project is partially supportive of this ancillary RCPG policy as it relates to the stated new technology project features, but not supportive of the policy as it relates to alternative waste management technologies. 39

14.5 *Facilitating regional dialogue on intercounty waste disposal projects.*

SCAG staff comments. The Draft SEIR presents a clear discussion of various alternative waste disposal facilities in Section 5.0 (Alternatives). The information presented is helpful in facilitating the regional dialogue on intercounty waste disposal projects. Furthermore, the Draft SEIR presents a case to support the selection of the proposed Project over the various alternatives noted in the Project Description. The Project is supportive of this ancillary RCPG policy. 40

Consistency with the 208 Plan for the South Coast Planning Area

As the designated Areawide Waste Treatment Management Agency for Southern California, SCAG is mandated under Section 208 of the Federal Clean Water Act [33 U.S.C. §1288] to engage in a comprehensive waste treatment planning process the primary product of which is the Areawide Waste Treatment Management Plan for the South Coast Planning Area (or "208 Plan"). Section 208(e) of the Clean Water Act provides that no NPDES permit may be issued for any point source which conflicts with the 208 Plan.

The current 208 Plan was prepared by SCAG in 1979. Due to a lack of federal or state funds, SCAG has been unable to update the Plan. Given the great demographic and environmental changes which have taken place in Southern California over the last two decades, the Regional Council has recognized that it is not feasible to determine whether a given project is consistent with the Plan. 41

While the statutes and regulations designate SCAG to make the conformity and consistency findings, the legal responsibility for these findings rest with the Regional and State Water Boards.

SCAG staff comments: As previously noted, the Project is consistent with SCAG's adopted population forecasts. These forecasts, however, have not been incorporated into the 208 Plan for the South Coast Planning Area. Furthermore, the various Residual Waste Management (especially Sanitary Landfill) policies and actions in the 208 Plan are dated SCAG is unable to make a finding that the Project is consistent with the 208 Plan for the South Coast Planning Area. SCAG and the State Water Resources Control Board are precluded from carrying out their mandated review responsibilities and the Project is currently inconsistent with the 208 Plan for the South Coast Planning Area and any NPDES permit issued for any point source associated with the Project would conflict with the 208 Plan.

Conclusions and Recommendations: 42

It is recommended that the Standing Committee on Implementation advise the City of Los Angeles that:

(1) As noted in the staff comments, the proposed Draft Supplemental Environmental Impact Report for the Sunshine Canyon Landfill is consistent with or supports many of the core and ancillary policies in the Regional Comprehensive Plan and Guide Until the funding of congestion mitigation improvements to Interstate 5 and impacted interchanges are resolved to the satisfaction of Caltrans and LAMTA, the Project can not be found consistent with core policy 4.10. The Project is conditionally consistent with core policies 4.20 and 4.23. The Project is partially supportive of ancillary policy 14.4, but not supportive of the manner in which it addresses alternative waste management technologies. Furthermore, based on insufficient information in the Draft Supplemental Environmental Impact Report, we are unable to determine consistency with core policy 5.11. 43

(2) For the reasons stated herein, SCAG is unable to make a finding that the Project is consistent with the 208 Plan for the South Coast Planning Area.

(3) All mitigation measures associated with the project should be monitored in accordance with AB 3180 requirements and reported to SCAG through the Annual Reasonable Further Progress Reports. 47

RE: **Supplemental Comments on the Draft Subsequent Environmental Impact Report for the Sunshine Canyon Landfill Expansion Project - SCAG No. I 9700400**

Dear Mr. Plafkin:

SCAG's Standing Committee on Implementation on November 6,1997 approved staff comments included in the September 4, 1997 letter on the. **Draft Subsequent Environmental Impact Report for the Sunshine Canyon Landfill Expansion Project.** They also directed that we include the following supplemental comments on the above referenced project. 48

1. The Final EIR should address the manner in which the proposed project deals with the potential problems (litter, dirt , debris and odors) associated with high wind events in the Newhall Pass area. The Committee chair was especially concerned about this problem because of the close proximity of the landfill expansion over portions of the previous City of Los Angeles site to adjacent residential areas. 49

2. The Final EIR should address the manner in which the proposed project addresses the relationship of potential surface and groundwater related problems associated with the Van Orman Reservoir and the Metropolitan Water District water treatment facility. The Committee chair and other committee members expressed concern about the potential damage to the regions water supply that could result from surface or groundwater contamination. 50

3. The Final EIR should address the manner in which the design of the liner system for the proposed landfill expansion can accommodate seismic events of the magnitude of the Northridge. Earthquake. The Committee chair expressed concern that given the past experience of earthquakes (Sylmar and Northridge) in the vicinity of the Santa Susana Mountains, the design of the landfill liner system should be such that any rupture resulting from ground shaking activity can be detected rapidly and mitigated. 51

If you have any questions regarding the attached comments, please contact Bill Boyd at (213) 236-1960.

Sincerely,

J. DAVID STEIN

SCH # 92041053 DRAFT SUBSEQUENT ENVIRONMENTAL IMPACT REPORT-SUNSHINE CANYON LANDFILL SEIR 91-0377-ZC/GPA (FILE NO. 88-076)

We have reviewed the subject document and offer the following comments:

1. Regulations

Regulations for municipal solid waste landfills are no longer found in Chapter 15, Title 23, California Code of Regulations. They are now contained in Title 27 of the California Code of Regulations which became effective July 18, 1997. In the future please reference the appropriate sections of Title 27. 52

2. Section 5.2.2 Material Parameters for Static and Pseudo-Static Analyses

The material parameters utilized for the solid waste materials must be consistent with the parameters used for the Stage II development of the Sunshine Canyon County Landfill (presently unapproved by this Regional Board). 53

3. Surface Water

Alteration of a streambed requires the approval of a Corps of Engineers 404 permit and a Regional Water Quality Control Board 401 Certification permit. 54

If you have any questions, please call Don Peterson at (213)266-7578.

Re: Sunshine Canyon Landfill Draft Subsequent Environmental Impact Report (EIR)

Dear Mr. Plafkin:

The South Coast Air Quality Management District (SCAQMD) appreciates the opportunity to comment on the abovementioned project. The comments included herein are meant as guidance for the Lead Agency and should be incorporated into the Final SEIR wherever possible.

Pursuant to Public Resources Code Section 21092.5, please provide the SCAQMD with written responses to all comments contained herein prior to the certification of the document. The SCAQMD would be happy to work with the Lead Agency to address these issues and any other questions that may arise. Please call Ms. Tara Tisopulos, Air Quality Specialist - CEQA Section, at (909) 396-3102 if you have any questions regarding these comments.

Sincerely,

Henry Hogo

1947 • 1997 50 YEARS OF PROGRESS TOWARD CLEAN AIR

Attachment 1

Comments on the Draft Subsequent EIR for the Sunshine Canyon Project

Section 1.7.1 - Unavoidable Significant Adverse Impacts

This section identifies significant adverse air quality impacts for various criteria pollutants [i.e., nitrogen oxides (NOx), reactive organic gases (ROG), and particulate matter (PM10)] due to project implementation. This section further states that "Regional emissions of all criteria pollutants [i.e., carbon monoxide, NOx, sulfur oxides (SOx) and PM10] will decrease by reduced mileage traveled within the South Coast Air Basin." The SCAQMD is unclear about why vehicle miles traveled (VMT) would be reduced, how they were derived, the specific amount of reductions being calculated, whether or not this reduction in VMT is included in the analysis of air quality impacts, etc. The SCAQMD does not see this information given in any greater detail in the Air Quality Impacts chapter. Therefore, please clarify these VMT reductions, in light of the additional trips being generated at this site, and provide all assumptions and calculations used. 55

Section 3.1.3 - Air Quality

Please note that the boundaries of the South Coast Air Basin do not include all of Los Angeles County, as of July 1, 1997, but rather, the non-desert portion of Los Angeles County. The SCAQMD's area of jurisdiction is different from the Basin and is as follows: the four-county South Coast Air Basin (Orange County and the non-desert portions of Los Angeles, Riverside, and San Bernardino counties) and the Riverside County portions of the Salton Sea Air Basin (SSAB) (formerly part of the SEDAB). 56

This section states that the Basin is currently in nonattainment for lead. This statement is incorrect and should be corrected in the Final SEIR. 57

Sections 4.2.5 and 4.2.10

These sections refer to the 1994 Air Quality Management Plan (AQMP). Please note that the most currently adopted AQMP is the 1997 AQMP. The 1997 AQMP has also been approved by the California Air Resources Board and forwarded to U.S. EPA as part of the State Implementation Plan revision. However, U.S. EPA has not taken any approval action on the 1997 AQMP. This document should be referred to in the Final SEIR. Copies are available through the SCAQMD's Public Information Center at (909) 396-3600. 58

Section 4.2.7 - Site Preparation/Construction Sequencing

The Draft SEIR does not include an estimate of the anticipated duration of construction activities. In addition, it is unclear whether or not any operation activities will overlap any construction activities. Any overlap between construction and operational emissions should be 59

discussed and analyzed to determine overall site-specific impacts. If cell filling activities are occurring at the same time construction is occurring, the entire process should be treated as operational, analyzed together, and compared to the operational significance thresholds to determine project significance.

Table 4.2-5 contains construction emissions for initial site preparation. This table includes emissions of particulate matter (PM10) with an estimate of 60.8 pounds per day. Table 4.2-6 shows fugitive dust PM10 emissions from initial site preparation to be 399.8 pounds per day before mitigation. The SCAQMD recommends that unmitigated PM10 emissions from Table 4.2-6 be included in Table 4.2-5 for ease in identifying unmitigated project emissions. 60

Based upon the materials received regarding the proposed project, SCAQMD staff was unable to locate any calculations conducted that support the emissions estimates listed in Table 4.2-5. In attempting to verify the results in Table 4.2-5, SCAQMD staff re-calculated some of the emissions in Table 4.2-5 and found that some of the emission factors used in the Draft SEIR were based on an 8-hour day, 7-hour day, etc. Since it is stated in the Draft SEIR that the normal workday is 10 hours, the Lead Agency should adjust the calculations to reflect a 10-hour work day in the Final SEIR. Re-calculating emissions based on a 10-hour workday may show that the construction phase of the project creates significant emissions for pollutants other than NOx and PM10. 61

This section indicates that the Lead Agency used EMFAC-7EP to model mobile source emissions. Please note that the California Air Resources Board (ARB) has a more recently approved and updated version of these emission factors, EMFAC-7G. The SCAQMD recommends that the Lead Agency revise for the Final SEIR its mobile source emissions results using EMFAC-7G emission factors to reflect the most accurate data currently available. 62

Section 4.2.7 - Fugitive Dust

The SCAQMD's strongly recommends that air quality impacts be calculated using approved emission factors such as AP-42 which are more conservative. Other emissions factors should not be used unless documentation is provided supporting the use other emissions factors. In the case of using fugitive dust factors from the Transit Mixed Concrete (TMC) site, there is no supporting documentation justifying its use for the proposed landfill expansion project. Further, the TMC site is located approximately 10 miles away from the proposed expansion site and may have completely different soil characteristics. The SCAQMD therefore recommends using the more conservative AP-42 emission factors to ensure that the analysis captures the maximum potential adverse impact from this source. 63 64

Section 4.2.8 - Air Quality Operational Phase

As indicated in the comments for Section 4.2.7 above , equations supporting the results in Table 4.2-7 were not included in the materials received by the SCAQMD. Project specific calculations 65

should be provided (in an appendix, for example) to facilitate corroboration of the results by the public. Similarly, many of the results provided do not reflect a 10-hour work day. The SCAQMD recommends that the Lead Agency revise in the Final SEIR the applicable factors from the CEQA Handbook to reflect the 10-hour work day. If adjustments have not been made, Table 4.2-7 should be re-calculated.

Tables 4.2-14 and 4.2-15

These tables display emissions, control efficiencies and remaining emissions in an effort to quantify the effectiveness of applicable mitigation measures. By the way the table is set up, however, it is unclear which specific mitigation measures are associated with the control efficiencies listed. For example, the SCAQMD has no way of knowing what mitigation measure is being described under CO - Heavy Equipment Operation, and how a control efficiency of 40 percent was determined. The SCAQMD recommends that the Lead Agency revise these two tables to include the mitigation measures specified in the text and associate the appropriate control efficiency for that mitigation measures for each emissions source. 66

Truck Travel and Fugitive Dust Emissions

Please specify the length of paved roads and unpaved roads being referred to in Tables 4.2-15 and 4.2-16. As stated previously, there are no specific calculations provided to show how these emissions were calculated, therefore, it is difficult to assess the validity of the control efficiency. 67

The text does not clearly state which criteria pollutants exceed both construction and operational thresholds. SCAQMD is unclear about the overall findings of significance for air quality. The SCAQMD assumes, based on Table 4.2-15, that emissions will remain significant for CO, NOx, ROG, and PM10 on an operational basis. Construction emissions should also be re-assessed, noting that potential re-calculations may be in order. The SCAQMD recommends that the Lead Agency include a table or discussion that aggregates all unmitigated emissions (both construction and operation) for clarity. 68

Section 7.0 - Mitigation Reporting

The SCAQMD has evaluated the Mitigation Reporting and Monitoring Program, Section 7.0, and concluded that several mitigation measures have inappropriately been assigned to the SCAQMD to monitor. Please refer to Attachment 2 for a list of mitigation measures over which the SCAQMD has no jurisdictional or enforcement authority. 69

Health Risk Analysis Air Quality Modeling

According to the Draft SEIR, the Lead Agency used the SCREEN2 model to estimate the ground level concentration for zero plume rise, flat terrain, and hybrid configuration scenarios. The SCAQMD recommends that the Lead Agency utilize the ISCST3 model. If the Lead Agency continues to rely on the SCREEN2 model, however, a clarification of what assumptions were used, how data were derived, etc., needs to be included. 70 Currently, the SCAQMD is unable to 71

replicate the results contained in the Health Risk Analysis. The SCAQMD also noted discrepancies between emission rates for criteria pollutants (Table 6, Appendix B-6 and Table 4.2-8, Volume 1). 72

Section 4.2.13 - Odor Impacts

The odor discussion in the text (page 4-94, third full paragraph) implies that the SCAQMD has determined that the Sunshine Canyon Landfill is not a source of odors. Although it is true that in some instances odor complaints in the area have been traced to other sources or the sources could not be verified, the landfill has been cited a number of times for verified nuisance odor complaints by the SCAQMD, particularly when it was in full operation. This paragraph needs to be revised in the Final SEIR to more accurately reflect the past history of nuisance odor complaints. 73

In the next paragraph on the same page, the text implies that the SCAQMD has approved as adequate the existing odor control procedures. This information is not accurate. Although it may be true that the existing odor control procedures are effective under certain conditions, they may not necessarily be effective under all conditions. There are a number of parameters that could reduce the effectiveness of the odor control procedures including meteorology, maintaining the equipment in good condition, etc. Further, there is no evidence in the Draft SEIR that the existing odor control procedures will be effective once the landfill has expanded. The extent of the expansion could render as inadequate any odor control procedures similar to those currently in place. Therefore, the text needs to be modified to reflect the fact that the SCAQMD does not necessarily consider the existing odor control procedures are effective under all conditions. 74 75

Further, the Lead Agency should provide additional information to support the assertion that the proposed odor control procedures will be adequate for the expanded landfill. 76

Attachment 2

Mitigation Measures Not Under the Jurisdiction of the SCAQMD

Construction and Operation

- The project proponent will maintain equipment in tune per manufacturer's specifications.
- The project proponent will use catalytic converters on gasoline-powered equipment.
- The project proponent will retard diesel engine injection timing by 2 degrees.
- High-pressure fuel injectors will be installed.
- Heavy equipment will use reformulated, low-emission diesel fuel.
- The project proponent will substitute electric and gasoline-powered equipment for diesel-powered equipment where feasible.
- Where applicable, equipment will not be left idling for prolonged periods.
- Public streets shall be swept at the conclusion of construction work.
- Refuse truck shall be maintained in proper tune.
- High-pressure fuel injector nozzles shall be used, and diesel engine timing shall be retarded by 2 degrees.
- Using a progressive fee schedule, the project proponent shall encourage trucks to carry full loads.
- The project proponent shall encourage trucking to be performed during off-peak hours.
- When operating onsite, trucks shall not be left idling for periods in excess of 5 minutes.
- Private owner-operators shall be warned that, if their trucks emit excessive amounts of smoke as determined by scale house workers, they will not be allowed future access to the landfill facility.
- Filling in each active area shall be prolonged through the utilization of a 20-foot maximum cell height.
- Solid waste shall be compacted within 1 hour of its arrival at the working face.

Mr. Hadar Plafkin
Los Angeles City Planning Department
Environmental Review Section
221 N. Figueroa Street, Room 1500
Los Angeles, California 90012

Dear Mr. Plafkin:

Draft Subsequent Environmental Impact Report
No. 91-0377-ZC/GPA for the Sunshine Canyon Landfill ...

The Metropolitan Water District of Southern California (Metropolitan) has received the Draft Subsequent Environmental Impact Report (SEIR) for the Sunshine Canyon Landfill in Sylmar City, Los Angeles County. The proposed project consists of the development, operation, maintenance, and monitoring of a Class III, nonhazardous solid waste landfill. This letter contains our response as a potentially affected public agency.

Our review of the Draft SEIR indicates four main areas of concern: (1) existing Metropolitan facilities; (2) groundwater and water quality concerns to Metropolitan's existing Balboa Inlet Tunnel regarding proper leakage detection of leachate; (3) surface water runoff; and (4) pest control and management.

Existing Metropolitan Facilities

The proposed project may adversely affect both the Metropolitan's Balboa Inlet Tunnel and the Joseph Jensen Filtration Plant located approximately ½-mile southeast of the landfill entrance. This plant delivers up to 750 million gallons of water per day to portions of the San Fernando Valley, Ventura County, and west Los Angeles County areas. It will be necessary for the City of Los Angeles Planning Department to consider these facilities in its project planning. 77

In order to avoid potential conflicts with Metropolitan's facilities, we request that preliminary engineering design drawings or improvement plans for any activity in the area of Metropolitan's pipelines and rights-of-way be submitted for our review and written approval. 78

You may obtain detailed prints of drawings of Metropolitan's pipelines and rights-of-way by calling Metropolitan's Substructures Information Line at (213) 217-6564.

Groundwater and Water Quality Concerns

The potential leakage of leachate into the groundwater basin, as well as contamination of surface water, is a major concern for this region. Metropolitan is primarily concerned that the Balboa Inlet Tunnel and subsequent water supply could be at significant risk from the potential leakage of leachate. The Balboa Inlet is a concrete lined tunnel located immediately southeast of the proposed leachate treatment facility. The tunnel lining could be subject to decomposition and corrosion by leachate. Should leachate come in contact with the tunnel, water quality could be severely compromised. The Final SEIR should elaborate upon the proposed mitigation measures for groundwater quality impacts. The measures mentioned in the Draft SEIR include the recovery and treatment of leachate onsite and the sampling of the treated leachate on a regular basis to affirm suitability for reuse. It is Metropolitan's understanding that treatment of leachate-contaminated water is not possible through the normal water filtration process. Only a sewerage treatment plant would be able to treat such water, and then it would be unusable for public consumption. The loss of valuable water resources and subsequent treatment would be at great expense to the public. 79

In addition, the Draft SEIR discusses using treated leachate water for dust control onsite. Though such use of treated water may conserve other important water resources, the Final SEIR should distinguish the parameters that assure leachate is nonhazardous and discuss the tests that will be used to verify its safety. Metropolitan is concerned that leachate sprayed upon surface roads may contaminate both underground and surface water sources. In addition, such treated water will also come into contact with Metropolitan's Balboa Inlet Tunnel. The project as proposed would not comply with the State of California Water Resources Control Board Chapter 15 requirements to protect underground water quality for as long as the wastes represent a threat to groundwater resources. 80 81 82

Surface Water Runoff

The Draft SEIR discusses proposed modifications to the existing drainage patterns. These improvements consists of surface water drainage channels, interceptor ditches, and pipelines that would collect, direct and convey surface water runoff around the landfill site and route runoff into regulated sedimentation basins. The drainage pattern indicated in Figure 4.3-1 of the Draft SEIR appears to be directing the surface runoff into the same channel that flows by Metropolitan's Joseph Jensen Plant. Metropolitan is concerned about the possible impact on its facility and requests that the downstream surface water discharge facilities or stream beds be analyzed for potential redirected storm flow impacts. 83

Pest Control and Management

Various bird species, in addition to ravens, may be attracted to the landfill. The proposed landfill will provide a readily available food source for these pest species. Subsequent migration of birds to our Jensen Plant filtration basins and reservoirs would increase the potential for contamination of the water supply. The Final SEIR should detail the provisions for minimizing bird and pest contact with the proposed landfill, for example, the amount of hours allowed before refuse is covered with soil, the potential for having exposed refuse over night or weekends, etc. In addition, Metropolitan requests that the Final SEIR discusses the bird and pest control measures to be implemented in the green waste/wood waste, recycling and public drop off area. 84 85

We appreciate the opportunity to provide input to your planning process. If we can be of further assistance, please contact me at (213) 217-6242.

Very truly yours,

For Laura J. Simonek
Principal Environmental Specialist

SUBJECT: Sunshine Canyon Landfill, EIR Case No. 91-0377-ZC/GPA

The Los Angeles County Department of Health Services, Solid Waste Management Program (SWMP) has reviewed the SEIR for the Sunshine Canyon Landfill project. Our comments are as follows:

1. Section 2.0 - Project description.

Paragraph 2.5.7. Proposed Landfill Ancillary Facilities

This section states (page 2-42) that as a component of the "green waste/wood waste recycling area" a dropoff and buyback recycling center would be established for use by the local community. Figure 2.4-5 locates this area on the opposite side of the site from the entrance gate. Will this location require users to travel along the same roads used by heavy trucks and other equipment to get there? Possibly the dropoff center could be located nearer the entrance gate. 86

Paragraph 2.10.3. Unloading Waste Materials at the Landfill Working Face.

This section is vague regarding self-haul loads. 87

a. Are these the same as those described later on as "local delivery?"

b. Will all self-haul loads go to the green waste/wood waste drop-off area? If so, how will waste materials get from this area to the actual working face? 88

c. The separation of public self-haulers from commercial delivery trucks (collection and transfer trailers) is a fundamental part of landfill design, primarily due to safety issues. This should be discussed further. One feature that might be incorporated into the overall site design is a self-haul "transfer station" near the scale-house. In this regard, small loads would be dropped off near the scale house and from there transported to the working face in operator owned transfer trucks. This would altogether eliminate the necessity for public self-haulers to commingle with heavy trucks. 89

2. Section 4.2 - Air Quality

a. The document identifies three means of transporting waste to the site: Transfer trucks, curbside collection trucks, and local deliveries. The document makes the following assumptions:

Type of vehicle.	% of vehicular traffic	% of waste delivered
Transfer truck	20	46
Collection truck	58	52
Local delivery	22	2 *

90

* The sentence in the last paragraph on page 4-66 should be corrected to read "These vehicles would account for less than 2 percent of the total *amount of waste* that would be delivered to the site."

Whereas transfer trucks are predicted to account for only 20% of the vehicular traffic, they will deliver 46% of the waste. A practical mitigation measure would be to allow delivery to the site only in transfer trucks. This would potentially eliminate up to 400 vehicle trips per day. Curbside collection vehicles should be allowed to deliver waste to the site only if traveling less than ten miles from the point of collection. The SEIR (page 4-65) states that curbside collection trucks may travel to the site from jurisdictions as far away as Santa Monica, Culver City, Beverly Hills, and Inglewood. Each of these jurisdictions has a transfer station within its city limits, or there are transfer stations located nearby. This particular requirement is standard at many landfills throughout the state (for example, Orange County landfills, see EIR page 1-16, and the Keller Canyon Landfill in Contra Costa County.) 91

b. The proposed mitigation measures relating to delivery vehicles (page 4-87) are weak and will be ineffectual. These consist, in the first two instances of "encouraging" haulers to do something, i.e., to carry full loads, and to use the site during off-peak hours. On page 2-74 it is stated that the frequent hauling of partial loads would result in a surcharge notice being assessed. Why not encourage utilization of the site during off-peak hours through a lower tipping fee? 92

c. It would be helpful to have further information regarding the data presented in Table 4.2-7. Are these emissions based on the amount of pollutants emitted from equipment in good, fair, or poor operating condition? If these figures are for vehicles in good or very good condition, it should be explained how a 40% efficiency reduction can be obtained (Table 4.2-15) by retarding diesel engine injection timing 2 degrees, or installing high-pressure fuel injectors as stated on page 4-87. It is also hard to see why these are considered "mitigation measures" since a prudent operator would do these things as standard operating practices anyway. 93 94 95

Page 4-68. Combustion of Landfill Gas Emissions.

a. The document states that "while the FEIR Sunshine Canyon Landfill Extension proposed a total of eight flaring stations within Sunshine Canyon, revisions in LFG generation calculations as well as experience gained in the generation rates associated with the existing inactive landfill have shown that two additional flare stations will be required for the project." This will actually be a *reduction* in the number of flares from the previously proposed eight to five. The document states that LFG generation calculations form the basis for the determination that only five flares will (eventually) be required, but these calculations are not included in the SEIR. 96

b. It is difficult to decipher Table 4.2-9. This table is labeled "Permitted Daily Emissions From Flaring Activities." Do the figures portray actual emissions? What are "permitted" emissions? There are apparently two permitted flare stations in the county and an "existing" flare station within the city. Text associated with Table 4.2-9 states that for CEQA purposes, the volume of emissions associated with the 'permitted' activities has been doubled to include both existing emissions, and the proposed project at buildout. Table 4.2-9 should clearly show the total amount of emissions associated with a specific number of flares, i.e., two or five or eight, or however many will eventually be constructed. 97

Page 4-88. Fugitive Dust

Emissions of fugitive dust or particulate matter are created primarily at the working face of most landfills rather than by vehicular travel over hard-packed roads, yet the SEIR proposes mitigation measures devoted almost exclusively to road dust and ignores the working face. The majority of pm10 emissions are created when refuse is dumped at the working face. These emissions are, admittedly, the most difficult to control: Delivery trucks may contain highly dispersive material, some of which may be toxic or unhealthful. At the same time, until the material is actually dumped there is no way of knowing what will come out of the truck. The SEIR, however, does not address this at all. It is suggested that as a mitigation measure a water truck, capable of discharging a high pressure spray, be permanently stationed at the working face to knock down any load containing dust or particulates. 98

Page 4-47

a. The discussion of wind conditions focusses mainly on general conditions throughout the Los Angeles basin and provides little information regarding site specific conditions. 99

b. Figure 4.2-2 purports to be a windrose for the Sunshine Canyon Landfill, yet the related text (page 4-47) is set in the context of general conditions within the SCAB. 100

Page 4-92

The statement dismissing the significance of odor from refuse is unsubstantiated in the real world. The terrain of this site will provide a conduit to carry odors directly toward the residential community to the southeast at least 10% of the time as shown on Figure 4.2-2. 101

Page 4-94

The "mitigation measures" proposed to minimize odors from refuse are either already required by law (i. e., the use of daily cover), are vague ("operational techniques" shall be utilized to control odor sources at the landfill.), or will be ineffectual (solid waste shall be compacted within 1 hour or its arrival at the working face.) It is suggested that as mitigation measures the operators commit to covering highly odorous loads immediately, or maintain a source of odor suppressant chemicals on-hand for use when necessary. 102

Section 4.3 Surface and Groundwater

Page 4-103.

The document should explain the difference between an individual point source NPDES permit and the statewide general NPDES permit program viz-a-viz monitoring and reporting requirements, and why the statewide general program was selected. 103

Section 4.5 Noise

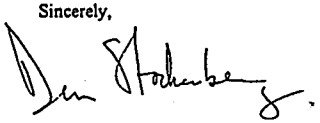
Paragraph 4.5.2. Operational Noise Impacts

a. This agency does not necessarily agree that just because " the noise emanating from the *existing, inactive* landfill ... is not audible to the residential developments located south of the project site ..." the conclusion can be drawn that sound from *proposed* landfilling operations would also be inaudible. It is stated in the SEIR that noise is audible if maintenance "equipment" is operating "near" the top deck area. The SEIR does not make it clear if this "equipment" would be consistent with the noise that could be expected from the type of equipment used in landfilling operations, nor does it make clear what is meant by "near" the top deck. 104

b. The SEIR does not address the noise that could be expected from the tub grinder which would be placed in the proposed green waste/wood waste processing area. This area is located at the closest point on the site to the residences to the south. 105

Page 4-219/4-220

It is stated in the SEIR that vehicles in excess of 6,000 pounds (gross) are prohibited from Balboa Boulevard. However, it cannot be concluded that "... landfill-bound truck traffic would not influence noise levels ... since these vehicles are prohibited from traveling along Balboa Boulevard." The SEIR estimates that up to 22 percent of the project related traffic may be due to local deliveries, i.e., vehicles less than 6,000 pounds. The proposed mitigation measures only address this issue by stating that "citizens, small commercial, and private users" shall be "encouraged" to use alternate routes. This may not be effective, however, in that Balboa Boulevard is the only practical route to the site from the communities of Granada Hills, Chatsworth, Canoga Park, and Reseda. 106



GENERAL

This SEIR (Table 3.2-1) defines the continuing operations of the county landfill as a 'related' project. In reality, the county and city portions of the site are each part of a single landfill. This document, therefore, describes only one half of the proposed landfill project - rarely are the cumulative impacts clearly addressed. In some respects this may be acceptable, e.g., the traffic analysis does factor traffic due to continuing operations into the background levels. In other cases, e.g., air impacts, it ignores the existing, and therefore cumulative, impacts from ongoing operations. 107

For example, the SEIR states that "Because the emissions associated with construction and operation of the cumulative projects cannot be determined without a full analysis of each project ... the cumulative analysis for the project's air quality must be generic by nature." This may be true in the case of some of the 33 projects identified as contributing to cumulative impacts, but it is not the case as far as the county landfill is concerned since that project was the subject of an in-depth study. The document is deficient in not providing at least some information in the cumulative impact section of each impact area. 108

Thank you for the opportunity to review and comment on this document. I can be reached at either (562) 438-6788 or (213) 881-4151 should you have any questions.

Sincerely,

Don Stockenberg, REHS

Los Angeles, CA 90012

Dear Mr. Plafkin:

RESPONSE TO A SUBSEQUENT ENVIRONMENTAL IMPACT REPORT (SEIR) - SUNSHINE CANYON LANDFILL PROJECT

Thank you for the opportunity to provide comments on the SEIR for the proposed Sunshine Canyon Landfill Project. These comments supplement the comments provided by our Department in a letter dated December 4, 1997. We have reviewed the SEIR and offer the following comments:

Traffic and Lighting

The proposed project is estimated to generate approximately 2,260 passenger car equivalent (PCE) trips per day, 245 and 285 PCE trips during the a.m. and p.m. peak hours, respectively. **109**

We agree with the traffic study that the traffic generated by the project will not have any significant impact on County intersections or roadways.

Traffic volumes indicated in Figure 4.13-14 (1998 A.M. Peak-Hour Background Traffic Volumes) of the SEIR are identical to those in Figure 4.13-15 (1998 P.M. Peak-Hour Background Traffic Volumes). This discrepancy should be corrected. **110**

We recommend the State of California Department of Transportation also review this project for impacts/mitigations within its jurisdiction. **111**

If you have any questions, please contact Mr. Garland Seto of our Traffic and Lighting Division at (626) 458-5909.

If you have any questions regarding the environmental reviewing process of this Department, please contact Mr. Vik Bapna at the address on the first page or at (626) 458-4363.

Very truly yours,

Mr. Hadar Plafkin, City Planner
Los Angeles City Planning Department
Environmental Review Section
221 North Figueroa Street, Room 1500
Los Angeles, CA 90012

Dear Mr. Plafkin:

SUBSEQUENT ENVIRONMENTAL IMPACT REPORT (SEIR)
SUNSHINE CANYON LANDFILL EXPANSION
CITY OF LOS ANGELES

Thank you for the opportunity to provide comments on the SEIR, dated July 1997 (State Clearinghouse Number 92041053), for the proposed Sunshine Canyon Landfill Expansion, City of Los Angeles. We have reviewed the subject SEIR in reference to areas of responsibility under the purview of the Environmental Programs Division of the Los Angeles County Department of Public Works (Department). The Department will be submitting additional comments under separate cover. The following is offered.

GENERAL COMMENTS

1. The California Integrated Waste Management Act of 1989 (AB 939), as amended, mandates the County to prepare a countywide siting element which must address the 15-year solid waste disposal capacity needs (1995-2010) of the unincorporated areas of the County, the City of Los Angeles, and other cities in Los Angeles County.

   The Department, under the auspices of the Los Angeles County Solid Waste Management Committee/Integrated Waste Management Task Force, prepared the Los Angeles County Countywide Siting Element dated June 1997 (June 1997 CSE). The June 1997 CSE was approved by a majority of the cities in Los Angeles County containing a majority of the cities' population in November 1997. The Sunshine Canyon Landfill Expansion, City of Los Angeles, has been identified in the June 1997 CSE. The proposed expansion will provide for a portion of the 15-year disposal capacity need identified in the June 1997 CSE. 112

2. Please revise all references to the "Los Angeles County Department of Public Works, Solid Waste Management Division" to read "Los Angeles County Department of Public Works, Environmental Programs Division" throughout the document. 113

SPECIFIC COMMENTS

1. Executive Summary, Section 2.2.1, Statistical Information in Connection with Solid Waste Generation and Permitted Capacity within the City of Los Angeles, page ES-11.

   As mandated by State law, the Department is responsible for collecting statistical data by jurisdiction of origin on the quantity of solid waste disposed at permitted solid waste disposal facilities in Los Angeles County. The Department is then required to consolidate this information and report the data to all appropriate cities and counties in the State of California. 114

   As discussed below and based on the data collected by the Department and reported to the City of Los Angeles and the California Integrated Waste Management Board, the information provided in Section 2.2.1 needs to be expanded/revised. The following identifies the quantities and distribution of that portion of the solid waste that was generated in the City of Los Angeles in 1995 and disposed of at permitted disposal facilities within and outside Los Angeles County:

   ♦ Permitted disposal facilities in Los Angeles County:

- Class III landfills	3,627,037 tons
- Unclassified landfills	145,239 tons
- Transformation facilities	56,525 tons

   ♦ Permitted disposal facilities outside Los Angeles County:

- Exports to Riverside County	4,623 tons
- Exports to Ventura County	8,630 tons
Total disposed	3,842,054 tons

   115

   Based on the 1995 estimated diversion rate of 40.6 percent listed in the above-mentioned Section and the above disposal quantities, the estimated solid waste generation rate for the City of Los Angeles in 1995 is 6,468,104 tons. Based on the estimated City population of 3,593,729, this translates into a per-capita waste generation rate of 1.80 tons of solid waste per person per year in the City of Los Angeles rather than 1.58 as listed in the document. 116

   All appropriate sections of the SEIR should be revised to reflect the above information.

2. Executive Summary, Table ES-1, page ES-13 (also shown on page 2-5 of Volume I).

Table ES-1 indicates that the information provided is based on the Preliminary Draft Los Angeles County Countywide Siting Element dated January 1996. However, the discussion fails to define the term "permitted disposal capacity." Please refer to Section 3.3.4 of the June 1997 CSE, page 3-4, and include the definition provided. The disposal quantities, remaining disposal capacity, and footnotes listed in Table ES-1 should be consistent with those provided in the June 1997 CSE. Additionally, footnote (d) of Table ES-1 should be revised to indicate that "The Chiquita Canyon Landfill has recently obtained a land use permit which provides for an anticipated disposal capacity of 23 million tons." 117 118 119

All appropriate Sections of the SEIR should be revised to conform with the comments listed above. 120

Additionally, it should be noted that the remaining combined permitted disposal capacity of all Class III landfills in Los Angeles County is estimated at approximately 86 million tons as of July 1, 1997. 121

3. Summary, Volume I, Section 1.9.1, Alternatives Not Evaluated, Mission/Rustic-Sullivan Landfill, page 1-12.

Revise this Section and other appropriate Sections of the SEIR to incorporate updated information on the status of the Mission/Rustic-Sullivan Canyons site, as identified in the June 1997 CSE. Specifically, the Mission/Rustic-Sullivan site is not identified as a possible landfill site in the June 1997 CSE. 122

4. Summary, Volume I, Section 1.9.1, Alternatives Not Evaluated, page 1-14, third bullet.

We agree that California's standards and requirements for the operation of disposal facilities are more stringent compared to other states. Additionally, disposal facilities located in Los Angeles County must operate under even more stringent conditions as mandated by local/regional agencies, as in the case of the Sunshine Canyon Landfill in the County unincorporated area. 123

5. Summary, Volume I, page 1-25, Status of Elsmere Solid Waste Management Facility, and Section 5.7.1, page 5-27.

Revise these Sections and all other appropriate Sections of the SEIR to incorporate updated information on the status of the Elsmere Solid Waste Management Facility, as identified in the June 1997 CSE. Specifically, they should reflect a proposed landfill capacity of 80 million tons exclusive of any Angeles National Forest lands. 124

6. Volume II, Appendices, page C13-2, Countywide Integrated Waste Management Plan.

Revise the definition of the Countywide Integrated Waste Management Plan to reflect the following:

- The Countywide Integrated Waste Management Plan also includes the Countywide Integrated Waste Management Summary Plan prepared by the County. 125

- The Countywide Integrated Waste Management Plan includes all Non-Disposal Facility Elements prepared for the County unincorporated area and each of the 88 cities located within Los Angeles County.

Subsequent detailed discussions of the various components of the Countywide Integrated Waste Management Plan should include a detailed description of the Countywide Integrated Waste Management Summary Plan, dated June 1997, which was prepared by the Department and approved by a majority of the cities in Los Angeles County containing a majority of the cities' population in November 1997. This document was prepared pursuant to the California Integrated Waste Management Act of 1989, as amended. 126

7. Volume II, Countywide Siting Element, page C13-3.

Revise the discussion to indicate that under current State law, the County of Los Angeles is mandated to prepare the Countywide Siting Element to specifically address the disposal capacity needs of the 88 cities in Los Angeles County and the County unincorporated communities for a 15-year planning period. 127

If you have any questions regarding the above comments, please contact the undersigned at (626) 458-3502, Monday through Thursday, 7:00 a.m. to 5:30 p.m.

Very truly yours,

HARRY W. STONE
Director of Public Works

M. MICHAEL MOHAJER

FORM GEN. 160 (Rev. 6-80)

CITY OF LOS ANGELES

INTER-DEPARTMENTAL CORRESPONDENCE

Letter 3.6-2

Date: October 22, 1997

To: Mr. Con Howe, Director
Department of City Planning
Attention: Hadar Plafkin

From: Homer M. Morimoto, Division Engineer
Development Services Division
Bureau of Engineering

Subject: Draft Subsequent Environmental Impact Report (SEIR 91-0377-ZC/GPA) for the Sunshine Canyon Landfill at 14747 San Fernando Road

In response to your letter dated July 25, 1997, the Bureau of Engineering has the following comments in connection with the above-captioned document:

STREETS:

San Fernando Road north of the project driveway should be improved by constructing concrete curb, gutter, and a minimum 40-foot half roadway with appropriate transition near the northerly property line to join the freeway off-ramp improvements to the satisfaction of the City Engineer. San Fernando Road south of the driveway has been improved per Plan No. P-34901. Additional widening and/or dedication may be needed subject to the LADOT review of the traffic study. 129

HYDROLOGY:

Grading Plan should be submitted to the Valley Engineering office of the Bureau of Engineering, should the drainage construction become necessary. 130

GEOTECHNICAL REVIEW:

The report is generally geotechnically acceptable. However, Section 4.1 indicates that secondary displacement due to faulting could cause 8 inches of displacement beneath the landfill. The impact of this displacement on the proposed liner should be evaluated. 131

If you have any questions regarding this report, please contact Mr. Ray Saidi at (213) 485-3091.

Environmental Review Section
221 North Figueroa Street, Suite 1500
Los Angeles, CA 90012-2601

Dear Mr. Plafkin:

Comments on the Subsequent Environmental Impact Report (SEIR)
Sunshine Canyon Landfill, EIR Case No. 91-0377-ZC/GPA

The Los Angeles Department of Water and Power (LADWP) welcomes the opportunity to comment on the Sunshine Canyon Landfill SEIR.

The LADWP's Water Services Organization provides the following discussion for your consideration:

- The area lies within the LADWP's 1805 Acreage Supply Charge (ASC) district and upon successful completion of the EIR process and the procurement of the necessary permits for the facility, the landfill project may be subject to the required ASC upon the owner's application for water service. **132**

- The subject area, consisting of approximately 194 acres within the City of Los Angeles, is to be utilized for landfill operations for the next 26 to 28 years. Upon closure of the landfill, this acreage could be extended to long-term nonuse. If ASC charges for this project are exempt because it is a City of Los Angeles facility, due consideration and review by the LADWP's Water Services Organization of the 1805 ASC rate may be required. **133**

- If there is any intended use of subsurface water (groundwater) or surface water (from precipitation or storm runoff) for irrigation or other consumptive use, approval must be obtained from the Upper Los Angeles River Area (ULARA) Watermaster. This landfill falls within the boundaries of the ULARA **134**

111 North Hope Street, Los Angeles, California *Mailing address:* Box 51111, Los Angeles 90051-0100
Telephone: (213) 367-4211 *Cable address:* DEWAPOLA *FAX:* (213) 367-3287

Recyclable and made from recycled waste.

watershed, and by adjudication all surface and subsurface water rights belong to the City of Los Angeles of which the Watermaster is the caretaker (enforcer) of those rights.

- Appropriate dust control measures must be provided. **135**

The LADWP's Energy Services Organization provides the following discussion for your consideration:

- Electrical service will be provided in accordance with the LADWP's rules and regulations. Electrical facility construction may cause limited temporary impact on the surrounding communities in the form of unavoidable noise, air pollution and traffic congestion during construction. **136**

If you require more information or have questions regarding the Water Services Organization's comments, please contact Mr. Douglas K. Sunshine at (213) 367-1162. If you require more information or have questions regarding the Energy Services Organization's comments, please contact Mr. Mark Williams at (213) 367-0270.

Sincerely,

Charles C. Holloway

CHARLES C. HOLLOWAY

FORM GEN. 160A (Rev. 1/82)

CITY OF LOS ANGELES
INTER-DEPARTMENTAL CORRESPONDENCE

Letter 3.6-4

San Fernando Rd
& Sunshine Canyon
Landfill Access Rd

Date: November 25, 1997

To: Hadar Plafkin, City Planner
Department of City Planning

From: Robert T. Takasaki, Senior Transportation Engineer
Department of Transportation

Subject: **SUBSEQUENT ENVIRONMENTAL IMPACT REPORT FOR PROPOSED SUNSHINE CANYON CITY LANDFILL EXTENSION PROJECT (SEIR 97-0377-ZC/GPA)**

The Department of Transportation (DOT) has reviewed the July 1997 Subsequent Environmental Impact Report (SEIR) for the Sunshine Canyon City Landfill Extension Project. The proposed project consists of the development and operation of a Class III nonhazardous solid waste landfill facility and an on-site green waste/wood waste recycling area on a 205 acre site. The project is contiguous with the previously approved Sunshine Canyon County Landfill Extension project located in the unincorporated County area of Sunshine Canyon and utilizing a common access driveway on San Fernando Road south of the I-5 southbound off-ramp and south of Sierra Highway. The proposed City Landfill project would have an estimated net airspace volume of approximately 31 million tons and with an average solid waste disposal intake of approximately 5,000 tons per day. The maximum daily intake for the proposed City landfill is 5,500 tons per day. The City landfill operation will be open for refuse disposal from 6:00 AM to 6:00 PM, Monday through Saturday, excluding Sundays and holidays. Except as noted, the content of DOT's comments and recommendations to offset the traffic related impacts of the project on the surrounding streets and intersections as outlined in our letter of March 12, 1996 have been included in the July 1997 SEIR. 137

COMMENTS

The Conceptual Mitigation Plans contained in Appendix F for the intersection of San Fernando Road at the project driveway show three schemes in which two are Interim Improvement Plans and the third is an Ultimate Improvement Plan for that intersection. Only the Ultimate Improvement Plan was discussed with DOT in our prior review of the traffic study. DOT prefers the Ultimate Improvement Plan (dual northbound left turn lanes) to the Interim Improvement Plans (single northbound left turn lane). Therefore, DOT recommends that the Ultimate Improvement Plan be required as the mitigation measure for this location. 138

On Pages 1-76, 1-77 and 1-78, Table 1.10-1, Summary Matrix of Potential Environmental Impacts, Mitigation Measures, Net Unmitigated Adverse Impacts, Mitigation Compliance Responsibility and Monitoring Phasing and Enforcement Program, please make corrections as follows: 139

- On Page 1-76, under Section 4.13.1 Traffic and Mitigation Measures Column
  Roxford Street at the I-5 Freeway, (SB ramp)
  - Restripe **westbound** ~~southbound~~ approach on Roxford Street to provide dual left-turn lanes and one through lane.

  Roxford Street at the Encinitas/I-5 Freeway (NB ramp)
  - Restripe **northbound approach** ~~westbound through lane~~ on Encinitas Avenue to **provide left-turn lane, shared through/left-turn lane and shared through/right-turn lane** ~~left/through option lane.~~ 140

- On Page 1-77, under Section 4.13.1 Traffic and Mitigation Measures Column
  San Fernando Road at Balboa Boulevard
  - Replace second paragraph to state:
    Contribute to the design, construction and operation of the Northeast Valley Automated Traffic Surveillance and Control (ATSAC) system for this intersection. The current cost of ATSAC for the Northeast Valley System is $79,000 per intersection. The contribution to ATSAC should be made prior to the start of construction for this ATSAC System which is scheduled for the year 2003. 141

  San Fernando Road at Sierra Highway
  - Restripe **northbound approach** ~~through lane~~ on San Fernando Road to **provide a shared through/right-turn lane and exclusive right-turn lane** ~~through/right option lane~~ **and restripe the westbound approach of Sierra Highway for a 12-foot wide curb lane.** 142

  San Fernando Road at project driveway
  - Replace paragraph to state:
    Install a new traffic signal and widen and restripe the northbound approach of San Fernando Road to provide dual left-turn lanes and two through lanes. Also contribute to the design, construction and operation of the Northeast Valley ATSAC system for this intersection. The current cost of ATSAC for the Northeast Valley System is $79,000 per intersection. The contribution to ATSAC should be made prior to the start of construction for this ATSAC System which is scheduled for the year 2003. 143

- On Page 1-77, Table 1.10-1 immediately after the paragraph on San Fernando Road at project driveway
  - Please add the following paragraph:
    The required street improvements and signal modifications shall be guaranteed before the issuance of any building permit for this project through the B-Permit process of the Bureau of Engineering, Department of Public Works and the Encroachment Permit process of Caltrans (where applicable). Construction of the improvements to the satisfaction of DOT, the Bureau of Engineering and Caltrans (where applicable) must be completed before issuance of any certificate of occupancy. Prior to setting the bond amount the 144

Bureau of Engineering shall require that the developer's engineer or contractor contact DOT's B-Permit Coordinator, telephone (213) 580-5336, to arrange a pre-design meeting to finalize the proposed geometric and traffic signal designs needed for the project.

- On Page 1-78, under Section 4.13.4 Parking and Safety Concerns and Mitigation Measures Column
  Replace paragraph to state that a new traffic signal at the project landfill entrance should be installed immediately prior to issuance of any certificate of occupancy for the project. 145

On Page 4-372, Table 4.13-9, PROJECT-SPECIFIC MITIGATION MEASURES, should be revised to reflect the above comments described for Table 1.10-1. 146

On Page 4-379 under City Mitigation Measure, replace the first bullet to state:

Prior to issuance of any certificate of occupancy for the project, install a new traffic signal at the project landfill entrance and widen and restripe the northbound approach of San Fernando Road at the project driveway to provide dual left-turn lanes and two through lanes. Also contribute to the design, construction and operation of the Northeast Valley ATSAC system for this intersection. The current cost of ATSAC for the Northeast Valley System is $79,000 per intersection. The contribution to ATSAC should be made prior to the start of construction for this ATSAC System which is scheduled for the year 2003. 147

This memorandum does not constitute approval of the driveways and parking scheme for the project. Those require separate review and approval and should be coordinated with the Citywide Planning Coordination Section (Room 460, Counter "O") as soon as possible to avoid delays in the building permit approval process. 148

If any questions should arise, please contact John Sam of my staff at (213) 580-5206.

Re: Comments On Draft Subsequent Environmental Impact Report (Draft SEIR) for Sunshine Canyon Landfill Expansion Project. Case 91-0377-ZC/GPA, Reference # SCH 92041053.

Dear Mr. Plafkin;

I am pleased to have the opportunity to comment on the Draft Subsequent Environmental Impact Report (Draft SEIR) for the Sunshine Canyon Landfill Expansion Project. As the Chairman of the City Councils Planning and Land Use Management (PLUM) Committee, I see many projects that have significant impacts on the City of Los Angeles and various neighborhoods. Rarely, do I see a project of this magnitude and negative impact. 149

As the elected representative of the 12th Council District, I have the honor of speaking for the residents of Granada Hills who bear the impact of this project. We have reviewed the above referenced document and request consideration of the following comments: 150

TRAFFIC

Issue #1. A current and reliable traffic study is needed for the SEIR and should include the following from a worst case scenario viewpoint: 151

- Existing and future average daily traffic (ADT) volumes
- Traffic generation (including peak hour)
- Traffic distribution
- Analysis of peak hour demand and capacity using volume-to-capacity (V/C) and level of service (LOS) methodologies for intersections along with current and projected capacities of local roads, state highways, and freeways that might be impacted

Special attention needs to be given to the following intersections: 152

San Fernando Road at Project Driveway;
San Fernando Road at I-5 Freeway (southbound off ramp);
San Fernando Road at Sierra Highway;
San Fernando Road at Balboa Blvd.

Issue #2. This project will be "truck intensive". This study should address the current amount of truck traffic and other vehicular traffic, and the amount by which vehicular/truck traffic will increase both during construction, operation, and upon project completion. Data provided by the proponent is outdated and taken at times when the city side of the landfill was closed and is therefore inaccurate. A new study should include current data with truck types noted and actual truck routes. 153 154

Issue #3. The SEIR uses outdated and incorrect information with projections to the year 1998. Since that time period is only a month away, the entire traffic element must be redone with projections through the year 2003 or more. 155

Issue #4. The truck analysis is incremental and does not take into account the cumulative impacts of the County and City landfill operations open at the same time. The analysis also does not include the inert truck traffic. 156

AIR QUALITY

There are numerous issues of air quality that must be addressed and mitigated.

Issue #1. One of the problems which led to the Zone Revocation hearings of 1988 was that significant amounts of trash and dust which were blowing in the wind and landing in the neighborhoods homes below the landfill, and the City and Counties water supply. Pictures of large plumes of dirt and trash billowing upwards of 500 feet in the air were submitted to the ZA for proof. Additionally, credit records, doctors records and other sensitive material was retrieved by local residents from locations in Beverly Hills, Culver City and Santa Monica, all cities utilizing the landfill at the time. We were never able to quantify the amount of trash and possibly contaminated particulates that may have entered the water systems which supply 80% of the City and large areas of Los Angeles County. This evidence led ZA John Parker to conclude " **in the context of the strong winds which blow from the north, this landfill is probably in a POOR location**". (emphasis added) 157

The history of the area shows that this pass is in a very high wind tunnel. High pressure zones from the upper deserts are compressed in the venturi of the pass and create extremely strong winds from the north. In 1989, a major fire erupted on the landfill property. The Los Angeles City Fire Department estimated winds of in excess of 75 MPH which whipped the flames along the foothills and destroyed 18 homes in Porter Ranch. The AQMD regulations 158 159 160

prohibit dust and other air contaminants being blown into the air. Sunshine Canyon has been closed on a number of occasions for this reason. Amazingly the AQMD rule excludes wind in excess of 25 MPH as an act of nature. Since there are frequent high winds that blow in this area then dissipate on the valley floor, AQMD rules rarely apply. A wind circulation and frequency study must be done prior to any approvals.

Issue #2. The applicant admits to unavoidable significant adverse impacts to air quality relating to operational aspects of the project in its Draft SEIR. Air quality impacts are expected to remain above significant levels for criteria pollutants nitrogen oxides (NOx), reactive organic gases (ROG), and suspended particulate matter (PM10) due to project implementation. These impacts cannot be mitigated to levels below significance. 161

Issue #3. Odor impacts. There is no evidence in the Draft SEIR that the existing odor control procedures will be effective once the landfill has expanded. The extent of the expansion could render as inadequate any odor control procedures similar to those currently in place. 162

This landfill has been cited a number of times for verified nuisance odor complaints by the South Coast Air Quality Management District (AQMD). Perhaps the applicant should use a high percentage of dirt as cover, rather than ADC, to mitigate odor impacts of operations. 163

Issue #4. Traffic errors and the impact on air quality is greatly underestimated. Without corrected traffic impact studies and truck counts, the SEIR is naturally deficient in any evaluation of air impacts. The traffic projections produced by a new study will cause all air quality projections to be re-evaluated and calculated. 164

ALTERNATIVES

Issue #1. The No Project alternative is not really a no project alternative. BFI states clearly that if the No Project alternative is chosen, they will seek expansion in the County. The premise of the landfill is to "alleviate disposal capacity shortfalls in Los Angeles County". It must be pointed out that there are no current shortfalls, even though predicted for the year 1993, it never happened, and the surplus of landfill space today remains significant. Likewise, if the No Project alternative is chosen, then the county permit expansion of up to 70 million tons would adequately protect against any possible future landfill shortage. 165

Issue #2. The SEIR addresses operational and near operational out of county and state rail haul sites and states that they "would result in disturbances on desert environments, the need for secondary transfer stations facilities, and the use of waste-by-rail systems, which would result in greater environmental impacts". This concept is hard to understand in light of the impacts that BFI causes on human beings. In their view the impacts to a vacant mine or open desert is more important than the health of 15,000 citizens who will live in the debris "drop zone" caused by wind blown trash. Likewise the potentialof water contamination to the two major fresh water storage reservoirs for over 15,000,000 people in the greater Los Angeles/Ventura County areas. 166 167

A more serious effort must be shown toward consideration of alternative sites. 168

Issue #3. The SEIR does not address the fact that the City of Los Angeles currently has issued an RFP to look at new technologies or alternatives to land filling. The SEIR does not look at new technologies. The County currently operates the SERF project, and a private contractor operates another facility in Commerce-- both are waste-to-energy facilities. These facilities are similar to the ones used around the world, and in areas such as Japan, where they eliminate nearly 100% of all waste WITHOUT LANDFILLS. In Hemet, a new facility is being experimented with using polymer's to inject into sorted trash. The end product is a usable brick. No mention of any of these new technologies is found in the SEIR and they need to be explored; particularly, in light of the City of Los Angeles' RFP. 169

Issue # 4. The lack of serious consideration of the Orange County landfills who are willing to accept some LA County waste. This option is a good short term solution to any disruptions that "Could" happen until a full rail haul system, or new technology system could be built. Suggested consideration should be made of utilization of existing landfills in the following manner: 170

Until the year 2006:

A. Olinda and Olinda Alpha landfill, Orange County.
B. Bowerman Landfill, Orange County.
C. El Sobrante, Riverside County. 171

After the Year 2006:

A. Mesquite Regional Landfill, Imperial County.
B. Eagle Mountain Landfill, Riverside County.
C. Bolo Station Landfill, San Bernardino County.
D. New technology in basin.

REGIONAL DEVELOPMENT

Issue #1. Since there have been over 64,000 proposed and/or permitted housing units for the areas to the north which lie in the Chiquita Landfill area, this growth does not place any additional need for Sunshine Canyon since Chaquita is scheduled to take their trash. However, the traffic patterns that this growth will create along the I-14 and I-5 corridors, which run next to Sunshine Canyon, is enormous. These cumulative impacts are not included in this SEIR. The Southern California Association of Governments (SCAG) will take this issue up and the SEIR needs to properly analyze these impacts. 172 173

WATER QUALITY

Issue #1. The landfill lies within one mile upwind of the MWD Jensen Filtration Plant and the DWP Los Angeles Reservoir. These two facilities supply most of the water for Los Angeles City, County and parts of Ventura County. The City Zoning Administrator has documented that the landfill is in a bad location due to the frequent winds in the area. The possibility of wind blown contamination is of such great significance that extensive wind modeling must be done to guarantee that there is no wind blown contamination. 174

Issue #2. The Inlet Tunnel of the MWD Jensen Filtration Plant is within ½ mile of the landfill leachate collection system. The BFI system is a concrete system which is subject to breakage in severe earthquakes or erosion. A better system must be designed to protect the MWD Jensen Plant. 175

Issue #3. Surface runoff from the landfill will empty into a channel that flows directly in front of the MWD Jensen Filtration Plant. Any breakage or overflow of this channel could cause significant contamination. BFI needs to find a better run off control system. 176

Issue #4. BFI rests all of its protection from ground water contamination on the fact that the landfill is lined. However, the liner is merely 60 mil thick and will not withstand movements of over 12 inches. The 1994 Northridge earthquake moved the peak above the landfill 15-18 inches. The active earthquake faults in the area raise this issue to a level of significance and the EIR does not show how BFI can satisfy EPA standards for municipal landfills if the liner was to be damaged by another 1971 or 1994 size earthquake. 177

Issue #5. The liner warranty is valid for only 20 years. Degradation of the liner would continue each year making it less likely to withstand earth movements. This raises questions as to whether the liner, after 5 or 10 years could withstand even a modest earth movement. The EIR needs to show a scale of strength for each year of operation, and how BFI can guarantee the protection of the water table in later years, or after closure. 178

Issue #6. Bird contamination. During the previous operations of the City Sunshine Landfill, large flocks of birds would land in the open faces of the landfill then travel the 1 mile to the Jensen Filtration Plant and Los Angeles Reservoir. Analysis must be done to show the potential aerial contamination of water supplies from these birds-- both from carried mater and droppings. 179

MISCELLANEOUS

Issue #1. Property values. As the Councilman for the Granada Hills area I have had reports of home sales falling out of escrow due to the disclosure of the existence of a landfill near the home. I have also heard from many people that their property values have suffered. BFI must 180

guarantee the value of all future sales. A real estate analysis must be done to protect home owners from negative value impacts and BFI must be forced to underwrite any losses.

Issue #2. Buffer Zone. The SEIR does not address the fact that the proposed 100 +/-acre buffer zone has a number of active uses in it. A buffer zone must be free of any active uses which BFI has planned in their so called buffer zone. BFI must either eliminate proposed and current flare stations, sedimentation basins, oil wells, office uses, and other landfill activities, or extend the proposed buffer zone. 181

Issue #3. Previous history. The abuses of BFI are well known to the City of Los Angeles Planning Department, Board of Zoning Appeals and City Council. During the previous operation of the city side of Sunshine Canyon, prior to 1991, BFI was cited for many violations of Zoning codes and Building and Safety codes. Zoning Administrator John Parker ordered BFI to conduct a health survey in the area to determine health impacts of the dump, in 1988. BFI has never complied. BFI promised to conduct the survey, then used legal trickery to get out of it. A health survey, although somewhat outdated now, needs to still be conducted to determine any impacts or diminution of the quality of health in the area south of the landfill since its re-opening. 182 183 184

Thank you for your consideration.

Sincerely,

HAL BERNSON
Councilman, 12th District

Mr. Hadar Plafkin, City Planner
Department of City Planning
Environmental Review Section
221 N. Figueroa Street, Suite 1500
Los Angeles, CA 90012

Subject: Review of Sunshine Canyon Subsequent Environmental Impact Report (SEIR) 91-0377-ZC/GPA, Dated July 1997
State Clearinghouse Number (SCN) 92041053

Dear Mr. Plafkin:

This review of the draft of the Sunshine Canyon Landfill SEIR was conducted by the Environmental Affairs Department Local Enforcement Agency (LEA). The LEA, in partnership with other state and regional regulatory agencies, has the responsibility for ensuring the proper permitting, operation and closure of solid waste facilities within the City of Los Angeles. As a responsible agency under CEQA, our comments are focused on the environmental, technical and operational impacts related to the solid waste facility permit, which is required and issued by the LEA only after local land use entitlements are granted. 185

Section 1.0 Summary

Section 1.2 Overview

The term 'Average daily capacity" for the City portion is stated as 5,000 tons per day. The daily capacity should be listed as a maximum daily capacity and not an "average." In section 2.6.2 it states a maximum daily intake would be 5,500 tons per day which is in conflict with the earlier stated figure of 5,000 tons per day. This is repeated throughout the document and is inconsistent with future permitting that may occur. One maximum daily tonnage figure should be used, and it should not be an "average" but a maximum figure. 186

Section 2.0 Project Description

Figure 2.4.5 Aerial Map

Provide an aerial map indicating where the location of the reduced volume alternative would be located in relation to the other alternatives. 187

Section 2.5.4 Working Arrangement

Although the project proponent may wish to pursue an agreement between the City of Los Angeles and County of Los Angeles LEAs on enforcement at the site, the possibility has not been discussed. The likelihood of a joint enforcement agreement is uncertain and is not an accurate reflection of the project's operational future. The Project Description should accurately reflect anticipated conditions. 188

Section 2.5.6 General Design Features of the City/County Landfill Facility

Portions of California Code of Regulations Titles 14 and 23 have been merged into a new Title 27. Title 27 will apply to the majority of landfill activities. However, other proposed on-site operations may continue to be regulated by Title 14 or 23. Reference to all applicable CCR Titles should be included. 189

Section 2.5.7 Proposed Landfill Ancillary Facilities

Page 2-42 Green Waste/Wood Waste Recycling Area discusses placement of this activity near the existing inactive landfill. A drop-off and buyback recycling center for the local community is also described. In order to reduce safety hazards to the public, these unloading areas should be separate from the working face utilized by commercial vehicles. 190

Section 2.5.7 Scale House and Check-In Facility

Pages 2-39 and 2-43 discuss moving the scale house operations into the City of Los Angeles portion of the site, closer to the landfill entrance. Any impacts associated with a reduction in the on-site queue space for vehicles or other equipment should be evaluated. 191

Section 2.6.2 City/County Landfill Disposal Capacity and Operational Site Life

This section discusses average waste intake and weekly averages. The project proponent may have reached an agreement with the County that was incorporated into the County issued solid waste facility permit conditions to limit incoming tonnage on a weekly average. However, this is a condition with no precedent in City-issued solid waste facility permits. The Project Description should accurately reflect anticipated conditions. 192 If the project proponent wishes to seek a similar arrangement, this should be noted as speculative and would be an option to be considered beyond a daily tonnage limit. 193

Emergency Drainage Pipe

Update applicable drawings to show location of the proposed 500' section drainage pipe that the project proponent is planning to implement as an emergency drainage control measure. Also show the parts of the pipe which will be underground. Add a description of how this drainage pipe will be integrated into the drainage control system in the proposed expansion of the landfill into the City portion of the site. 194

Section 2.6.3 Waste Cell Development

This paragraph discusses the use of 9 inches of clean daily cover material. Page 2-42 of the SEIR also discussed the use of alternative daily covers such as green/wood waste alternative daily cover material. If alternative daily covers, other than clean soil are anticipated to be used, the associated impacts should also be evaluated in this document. 195

Section 2.7.7 Monitoring and Controlling Landfill Gas

The SEIR states that "One probe per 1,000 sq. ft. of landfill perimeter is proposed to be installed in locations of greatest concern." Be advised that the City of Los Angeles "Minimum Regulations for Sanitary Landfills in the City of Los Angeles" September 22, 1971, Amended December 7, 1973 III Dump (Operations and Maintenance) O.1. requires that gas probes be placed at 300-foot intervals. We have enclosed a copy for your information. The project description should be amended to incorporate the required City of Los Angeles probe spacing. 196

Section 2.8, Designated Local Enforcement Agency

The SEIR states that the City and County will enter an agreement where a joint authority will exercise common power over the entire project site. No discussions have taken place between the City of Los Angeles LEA, County of Los Angeles LEA or the project proponent on the development of such an agreement. The likelihood of such an agreement is speculative. The project description should discuss operation of the site with two separate LEAs. Any discussion of a joint enforcement should only be a secondary description. 197

Section 2.7.3, Waste-on-Waste Liner System and Figure 2.7-3

Page 2-57, The Figure 2.7-3 is inconsistent with the text. The text on page 2-57 states that the waste-on-waste liner is over engineered final cover on the side slopes of the inactive landfill. The drawing shows only a existing intermediate cover of two (2') feet under the waste-on-waste liner system. 198

The existing proposed closure design for the inactive City landfill portion has a six (6') foot monolithic final cover over waste. Revise the drawing to show that the waste-on-waste liner system is on the final cover and the thickness of the final cover is a minimum of six feet. 199

The Local Enforcement Agency considers the "low permeability soil liner" as part of the "liner system" and not part of the foundation layer. The text is unclear on whether or not the low-permeability soil liner is part of the "foundation layer." The text in Section 2.7.3 states that the waste-on-waste liner system has a compacted soil foundation layer (from the drawing, we assume it to be the buffer soil and subbase layers) next to the low-permeability soil liner layer of the waste-on-waste liner system. 200 201

Please clarify in the text that the subbase and buffer soil is the foundation layer that is referred to in the text and that the foundation layer sits on top of the final cover of the inactive City landfill. Add a label on the drawing showing what constitutes the "foundation layer."

Section 2.10.3 Unloading Waste Materials at the Landfill Working Face 202

Refer to comments on section 2.5.7 regarding unloading areas for green/wood waste materials.

The SEIR should clearly state that a load check program will be a requirement of the City of Los Angeles solid waste facility permit. Landfill personnel, not LEA inspectors, will be required to randomly select loads and inspect them for hazardous waste. The LEA will monitor implementation of this load check program by landfill personnel. 203

Section 2.13.1 Personnel Training

Facility personnel should also receive training in recognition of subsurface fires and procedures to respond to such an emergency. 204

Section 2.15.1 End Use of the Site

Insert a description of what happens with the proposed end use of the site under the existing closure plan. The following text summarizes the Local Enforcement Agency's position. The inactive city portion of the Sunshine Canyon Landfill is currently undergoing Final Closure Plan approval. Should the proposed landfill expansion project be approved, the proposed end use of the site and the closure conditions (under the existing closure plan for the inactive City portion which in affect at the time) will need to be revised and incorporated into the new closure plan which is to be submitted as part of the permit application to the Local Enforcement Agency. In any case, final cover will be installed on the currently inactive City portion landfill of the site. 205

Section 3.0 Environmental Setting

Section 3.1.7 Light, Local Setting

The description of existing light sources should also include a discussion of light sources used by the existing landfill to illuminate the various working face locations after dark. 206

Section 3.1.11 Transportation and Circulation, Local Setting

It is strongly suggested that an analysis be included in the SEIR on whether a traffic signal should or should not be installed on San Fernando Road at the entrance to the landfill due to the high volume of two-way traffic on San Fernando Road. 207

Section 4.0 Environmental Impact Analysis

Throughout the impact analysis section, mitigation measures include performing activities in accordance with various rules or regulations. These actions should not be considered as mitigation measures, but as operating minimums. Specifically, 208

designs, construction, and operations conducted in accordance with the California Code of Regulations Titles 14 and 27 are expected minimums. If these regulatory minimums are carried out consistently, impacts should be minimized. However, measures taken beyond these regulatory minimums would and should be considered as mitigation measures.

Figure 4.1-1 Existing and Anticipated Soils Stockpile Areas 209
This figure shows that soil will be stockpiled on the top deck of the existing inactive City landfill. Impacts resulting from stockpiling of soil in this area need to be evaluated. Areas covered by the soil stockpile will not be able to achieve permanent vegetative cover until the soil is removed. Settlement of the surface by the surcharge of a soil stockpile should also be evaluated along with any other potential impacts. 210

Section 4.1.4 Geologic Hazards –Seismicity
Page4-40 City Mitigation Measures. It is recommended that provisions be made for a back-up generator to supply power to the gas flare system in the event of any extended power outage. 211

Section 4.2.8 Air Quality Operational Phase (Long-Term)
Page 4-70 Active Working Face Area. The SEIR states that unloading of refuse would not create substantial quantities of dust emissions. Have there been any measurements of dust generation during refuse unloading? Depending on the method, manual vs. automated, and the type of wastes, demolition inert vs. food waste, varying amounts of dust could be generated. Include a discussion on how the determination of insignificance was reached. 212

Combustion of Landfill Gas Emissions
What is the basis for doubling the current emissions limit under the existing SCAQMD permit (3 stations) for flaring LFG to account for both existing (1 station) and future buildout (5 stations) conditions? 213

Section 4.2.13 Odor Impacts
Potential odors associated with the storage and processing of green/wood waste materials could result in negative impacts. These impacts should be evaluated along with possible mitigation measures. 214

Refer to comment on section 2.7.7 Monitoring and Controlling Landfill Gas for sample probe installation. 215

Installment of an odor neutralizing or deodorant misting system should be considered as a mitigation measure in areas of potential odor sources. 216

The SEIR indicates LFG may be used to produce electricity (Pages 4-83 and 4-95). What are the environmental impacts associated with this activity? In what environmental document are these impacts evaluated? If there has not been an 217

analysis, there should be an explanation that when project information is known, there would be a separate environmental review

Section 4.5, City Noise Standards
Page 4-205, Paragraph 4, Plans, and Policies. The section states that "...continue to regulate construction or excavation noise between the hours of 9:00 p.m. and 7:00 a.m. of the following day..." This statement conflicts with the second bullet item "Construction Noise" on the same page. This bullet item states that the limits are between 7:00 A.M. and 6:00 P.M. Verify the correct limiting hours of the City noise ordinance. 218

Sections 4.6 Light and Glare
The environmental impact discussion states that the landfill would be operational during the hours of 5:00 AM to 6:00 PM. While this may be the hours that waste is accepted, the project description states that operational activities such as maintenance would be conducted until 9:00 PM. The potential for light and glare impacts and other environmental impacts from maintenance operations should also be evaluated. 219

Section 4.9.1 Hazardous Materials
Page 4-293, Paragraph 2. If during a load check, or during regular operations hazardous materials are found, the supervisor must contact, in addition to Cal-EPA and DTSC, the Los Angeles County Fire Department Health Hazardous Materials unit. 220

Section 4.9.1 Cumulative Impact
Page 4-296, Paragraph 3. The section states "Buildout of residential projects would increase the amount of HWW inadvertently disposed of in the solid waste stream." Note; Buildout of residential projects will not increase amount of HHW (not HWW), what may increase the amount would be an increase in permitted tonnage which in turn would result in a cumulative increase in HHW. 221

Section 4.9.1 City Mitigation Measures
Page 4-297, Bullet 5. We recommend the mitigation measure for load checks be increased from 1 in 1,000 tons, to 1.5 in 1,000 tons to be more protective. 222

Page 4-297, Bullet 6. DTSC will not provide a hazardous waste identification, that would be provided by the operator or Los Angeles County Health Hazardous Materials unit. 223

Page 4-297, Section 4.9.1. Bullet 9. The City will not "deem an inspector to be qualified through training and experience..." The inspector referred to must be identified clearly. If the inspector is an employee of BFI who will conduct hazardous waste load checks, then it is BFI's responsibility to deem the inspector qualified. The City currently assures that all LEA inspectors are qualified. 224

Section 4.9.2 - Vectors

Environmental Impact (paragraph 1, page 4-300). Oversized tires are often used at landfill sites for road demarcation and securing tarps, etc. Standing water tends to accumulate in these tires, especially after heavy rainfall. This document should include control measures outlining how the operator intends to prevent tires from attracting and propagating vectors on site (especially mosquitoes). If the operator is not going to use tires on site, then inclusion of these control measures is not necessary. 225

Section 4.9.3 - Litter

City Mitigation Measures (paragraph 2, page 4-305). Clarification is needed regarding the phrase, *"...periodic application of cover material during the day and at the end of the working day..."*

Is the operator going to apply cover material periodically throughout the day at the working face? Is this in addition to applying a full daily cover at the end of each operational day? If so, then these two different activities must be distinguished and clarified. 226

Section 4.13.5 Access Roadway in Sunshine Canyon

Realignment of the haul road and relocation of the scale house has the potential to effect the number of vehicles that are able to queue on-site. Approximately how many vehicles will be able to queue on-site after relocation of the scale house? 227

Section 4.14.1 Fire an Emergency Medical Services

The storage of green and wood waste should be discussed as a source of potential combustion. Measures to control any such fires should be explored. 228

Section 7.0 Mitigation Reporting

Table 7.4-1 - Mitigation Reporting and Monitoring Program (MRMP)

4.2.12 – Operations: Construction Equipment (page 7-10). Remove City LEA as an Enforcement Agency. 229

Page 7-26. The following mitigation measure requires further explanation: "Full-time inspectors shall be employed onsite for inspection of waste materials. Full-time inspectors shall be deemed by the City to be qualified through training and experience to perform assigned duties." 230

State who would employ these inspectors. (City of Los Angeles, BFI, or another party? 231 If full-time inspectors are deemed necessary, which City department is responsible for ensuring inspector qualification and training? 232 If the City LEA is responsible then it should be so stated.

Section 7.7 Public Access to Records

State where a public records file will be maintained, such as at a local library. Indicate if regulatory agencies inspection reports will also be included in this file. 233

Section 7.4 Designated LEA

The City of Los Angeles LEA is the designated LEA for the City. BFI cannot designate another LEA. This needs to be made clear in the document. 234

In the Summary Matrix of the environmental impacts under the category Operations 4.2.12, Refuse Trucks page 12, the LEA should be deleted as the monitoring agency for truck operations activity such as truck idling, truck arrival times, and truck loads as these are not LEA requirements. 235

If you have any questions, please call Josephine Gonzalez, LEA Program Environmental Supervisor at (213) 580-1073 or me at (213) 580-1068.

Sincerely,

Wayne Tsuda, Director
Materials and Waste Resources Division

MINIMUM REGULATIONS FOR SANITARY LANDFILLS IN THE CITY OF LOS ANGELES

Landfills

(Combustible, Non-Combustible Materials)

September 22, 1971
As Amended December 7, 1973

In accordance with Section 66.15 of the Los Angeles Municipal Code, the Board of Public works may issue revocable permits for the operation of "Fill and Cover" dumps, if in the Boards discretion such dumps are in the public interest. Permits for such dumps will be issued only to the operators.

The following rules and regulations have been established by the Board of Public Works under authority granted in the Los Angeles Municipal code. However, each permit for a dump is issued only after investigation by the Board and the other agencies concerned, of the particular site under consideration.

Specific regulations are set up in each separate permit. These may be more restrictive than the rules and regulator's set forth herein. Deviations may also be granted in accordance with Section VII herein.

I. APPLICATION - REPORT AND PLAN

A. Applications shall be filled with a report that includes the following:

1. Applications for a permit shall be sworn to and include the name, address and telephone number of the proposed operators legal description of the site; name and address or the owner of the site copy of lease or other documents under which the proposed operator is authorized to use the land if he is not the owner.

2. Applications for renewals shall be submitted in writing accompanied by the required bond and a sworn statement as to whether there has been any change in the information submitted with the original application.

3. The name, address, and telephone number of the manager or foreman.

4. Any fictitious name proposed to be used.

5. The proposed method of operation, including the location and depth of cuts, type and availability of equipment to be used, source and quantity of all cover material, water supply, and sewage disposal.

6. Any request for deviations from the rules and regulations together with the reasons therefor, made in accordance with Section VIII.

I. APPLICATION - REPORT AND PLAN (CONT'D)

B. Permits will be issued only to operators.

C. All applications for dump permits shall include a map and plan giving pertinent information relative to the following:

1. The site in its entirety.
2. The current ground water level and maximum high water level of record.
3. Any water ways or channels adjacent to or likely to affect the site.
4. Location of and pertinent information relative to water wells, active or inactive, and springs.
5. The contours of the dump site before and after filling.
6. Type of underlying soil.
7. Existing building locations and proposed building locations.
8. Intended points of ingress and egress, including roads and ramps and including existing or proposed paving or means of controlling dust in streets to be used for ingress and egree which are adjacent to developed areas.
9. Location and type of fence.

10. The operator shall file a report on how much of the filling has been completed and estimated time for completion of the dump, also hours and days of operation, and prices for accepting materials. This shall be due at the time of renewal of a permit or filing of an original application.

D. 1. Seven sets of plans and reports shall be submitted to the Department of Public Works. These are to be checked and approved by all departments or agencies involved before a permit is issued.

2. Permit will be granted only if roads to and from the site which are adjacent to developed areas are paved or a satisfactory method of dust control is installed and maintained.

II. INSPECTIONS

The Board of Public Works of the City of Los Angeles, the Los Angeles County Health Department, the Los Angeles Department of Water and Power, the Los Angeles Fire Department and the State Regional Water Pollution Control Board may make inspections, of the premises involved, the materials accepted for dumping on said premises, and the methods employed in cutting, dumping and filing operations.

III. DUMP (OPERATIONS AND MAINTENANCE (Combustible Dumps)

A. All waste materials placed in the dumps shall be spread, repeatedly run over with a bulldozer and otherwise effectively compacted in successive layers of not to exceed 3 feet compacted depth, except for solid, non-combustible material which is larger than 3 feet in its least dimension. Compaction of all waste material shall be done so as to adequately reduce voids and level the surface to properly support the earth, sand or other approved covering material.

B. Watering may be done to aid compaction providing the quantity and quality of water applied and the method or location of application does not result in ponding to the extent as may cause leaching or otherwise result in leaching from the disposed rubbish or other waste material into, or contamination or pollution of underground water formations. Such watering shall not soak substantial masses of manure and similar materials to such and extent as would be likely to produce spontaneous combustion. Wetting shall be discontinued or sufficiently reduced when the authorized enforcement agency determines such wetting is or may contributing to or producing a neighborhood odor nuisance.

C. Whenever the depth of compacted waste material reaches a maximum of 9 feet the surface shall be suitable leveled, compacted and then covered with earth, sand or equivalent approved materials to provide a depth of such cover of at least 9 inches. Suitable stakes, markers or other approved means shall be provided and maintained when necessary to aid the operator in keeping within this requirement or to aid inspectors in checking compliance.

D. All deposited waste materials shall be covered as required in "C" with the close of each working day, all rubbish not permanently placed and compacted as specified above shall be covered with sufficient earth, sand, gravel, decomposed granite, or other approved material so that no rubbish or refuse is visible on the site. (Section D adopted December 7, 1973).

E. The top surface and all side slopes of all completed lifts shall be maintained so that no rubbish or refuse shall be visible through the cover material and so maintained as to prevent fire and visible discharge of vapor or smoke. Regarding or recovering shall be done as necessary.

F. When the dump is filled to finished grade a final seal of at least 3 feet or well compacted, approved materials shall be applied to the top and all side surfaces, including the completed working face. After any portion of the dump has been filled to finish grade, the final 3-foot seal shall be placed on all such filled area within 60 days. The slope of any finished surface shall not exceed 30 degrees from the horizontal. All finished slopes shall be protected in an approved manner from erosion or similar effects by planting, provision of drainage structures or other methods of equal effectiveness. (Section F Amended December 7, 1973)

G. Dumping operations shall be limited to a working face of not over 150 linear feet in length for each bulldozer. Each bulldozer required herein shall be kept ready and available for leveling and compacting on the dump site at all times when dumping is permitted and shall be operated as much as necessary to meet all requirements hereof.

H. Manure and quantities or masses of organic food wastes, grass cuttings and similar materials shall be spread to a depth of not to exceed 2 feet and, insofar as practical, shall be mixed with other refuse. Such manure and similar materials shall be promptly and thoroughly covered with rubbish and other waste or with approved cover material. The equivalent of only one 2-foot layer of manure or similar organic waste material will be permitted for each 9-foot lift.

I. Waste containing magnesium, oils, paints, varnishes, drugs, medicines, chemicals, phenols, or creosote compounds, acids, brines, caustics, organic industrial waste, dead animals or fowls, garbage, waste from privies or chemical toilets, oil well brines, contaminated and/or oil well drilling muds, oil dehydration tank wastes, tank bottoms, acids sludges, and other liquids, solids, substances or other materials which may deleteriously affect a water supply shall not be accepted for disposal at the sump unless specifically permitted and approved as a deviation under Section VIII hereof.

J. No open fires or burning of any type shall be permitted on the site. Any and all comfort heating devices maintained on the premises shall be approved by the Fire Department.

K. A representative of the dump operator shall be present during dumping operations to control and supervise the activities.

L. The permittee shall remove daily all rubbish that has been dumped within any portion of a public street abuting the disposal site.

M. If found by the Board to be in the public interest, the permit may include the requirement for posting prices and hours when the dump is to be open to the public, and the requirement that the permittee accept rubbish from any person paying the posted fees during those hours. Such signs shall include the name and telephone number of the operator of the dump and a telephone number that one may call during non-operating hours. The information shown on the signs shall not be changed prior to filling with the Board any such change.

N. Dirt may be excavated to elevations established by the permittee and stockpiled on the premises, but shall not be removed or hauled from the dump site without the written permission of the Board of Public Works. (Section N adopted June 2, 1967).

O. Permittee shall be required to confine, to the area covered by permit, gases that originated from the deposit of combustible materials that my be explosive and/or potentially harmful in nature.

1. Permittee shall furnish monthly a report signed by a responsible testing company of readings at each of the test holes placed at 300-foot intervals around perimeter of site indicating the amounts of gas or gases present. Said test holes shall be made accessible to authorized representatives of the Board of Public Works for any tests considered necessary and the expense thereof shall be borne by the Permittee.

2. Any system installed and maintained to prevent migration and eliminate gases shall be subject to approval by the Board of Public Works and other appropriate Agencies.

IV. NON-COMBUSTIBLE DUMPS

Dumps used exclusively for waste material classified as inert or non-combustible material shall be maintained and operated as to avoid creating a dust nuisance. All material shall be placed, leveled or maintained so as to avoid creating rodent harborages.

V. TOILETS

Toilet facilities shall be provided and properly maintained on all dump sites and within 300 feet or the dumping operation. An approved portable chemical toilet, either on wheels or skids, may be used in lieu of a water flushing type toilet.

VI. FENCING - RODENTS AND NUISANCES

A. The property shall be provided with an approved and suitable type of fence or barrier to prevent unregulated or unauthorized entry or dumping. Gates shall be kept closed and locked during hours when the dump is not open for business. Where the operating area is adjacent to or clearly visible from developed property or a street designated as an important traffic artery, it shall be screened by solid fencing or planting of an approved type to a height of 6 feet. Said fence or planting shall be properly maintained at all times.

Suitable fencing shall be maintained where necessary to prevent a neighborhood nuisance caused by windblown paper and debris.
All wooden fences upon any portion of the property covered by the permit shall be neatly painted or stained, and maintained in good repair so as to present a reasonably attractive appearance.
A 6-foot solid fence of approved material shall be maintained along the entire length of the south property line of the dump sites (Wilmington District) or, in lieu thereof, shrubbery may be planted and properly maintained at all times to form a solid 6-foot hedge, provided a 6-foot chain link or suitable wire fence is maintained in connection therewith.
In lieu of the above requirements of this section, the Board may require the permittee, after determining that it is in the public interests, to install and maintain one or a combination of the following methods of landscaping and fencing around any portion or all the disposal site:

1. An 8-foot solid wall, or an 8-foot solid fence, provided with shrubs, plants, or hedges, having a height of at least 3 feet at the time of planting, which will, upon maturity, screen at least 25 per cent of the length of the fence; or

2. An 8-foot chain link fence <u>and</u> earth berm with a height of at least 6 feet, covered with acceptable plants or shrubs, with the berm being on the inside of and immediately adjacent to such fence; or

3. A 6-foot chain link fence topped with 3 strands of barbed wire for a total height of approximately 8 feet with a dense planting screen consisting of evergreen trees and suitable shrubs having a minimum height of 6 feet at the time of planting, adjacent to the interior of the said fence. Subsection 1, 2 & 3 Adopted: August 29,1969

B. No salvage operations will be permitted unless specifically authorized by the permit. Where salvage operations are permitted the salvaged material shall be removed from the premises daily or stored in a closed building of an approved type or within a vehicle as defined in the Vehicle Code, State of California. The residue from salvage operations shall be placed in the current dumping area and covered with earth before midnight daily.

C. Approved methods shall be used to minimize dust in the operations of the dump.

D. Install and maintain in good condition a 20-foot paved roadway within the disposal site from the adjoining public thoroughfare for a minimum distance of 300 feet beyond the entrance and exit gates.

E. Sheds and other building shall be constructed in such a manner as to prevent rodent harborage, be neatly painted or stained and maintained in good repair so as to present a reasonably attractive appearance.

F. Inspection of the premises shall be made by the permittee or his responsible representative at least once each operating day for rodents, insects, vermin and for burrows, droppings, larva or other evidence of vectors. Any infestation shall be immediately controlled by the proper use of poisons, or other suitable remedy, and the area involved shall be subsequently covered the same day with at least one foot of earth, sand, or other approved material.

G. a report shall be filed with the Board, signed by a responsible pest control company, at least once a month showing that the premises have been checked for rodents, the results of such inspection and what measures were taken with respect thereto.

VII. WATER SUPPLY AND DRAINAGE CONTROL

A. An approved water supply for firefighting purposes shall be provided on the premises.

1. Said supply shall be sufficient to supply at least two 1 1/2-inch hose lines each equipped with 1/2-inch nozzle tips in such a manner that they discharge a workable stream for a minimum distance of 20 feet when operating simultaneously. All hose and nozzle tips shall be kept in good condition and ready for instant use.

2. Each hose line shall be limited to 100 feet in length.

3. The hose shall be located so as to cover all portions of the working face of the dump which it is to serve.

4. In the event that the salvage operations are located so that the hoselines will not suffice, then additional fire protection will be required.

5. Water lines supplying the fire hose need not be buried.

6. Additional pipe shall be installed as the working face of the fill progresses, such pipe to be of adequate size and installed in such a manner as to allow for friction loss as the distance to the sump face increase, in order that sufficient volume and pressure may be had at the nozzles at all times.

B. An approved sanitary drinking supply shall be provided on the site.

C. All surface waters shall be diverted from the site so as to prevent percolation through any of the dumped material or erosion of the cut sections of the dump. This diversion may be accomplished by placing an impervious dike around the dump area, taking all precautions necessary to assure that any waters diverted by said dike shall be guided to proper storm drain facilities, or as so ordered.

D. Dumping operations shall be kept a distance of at least 50 feet from the official right-of-way of any watercourse or proposed drainage channel unless a lesser distance is specifically permitted and approved as a deviation under Section VIII.

E. No excavation shall be made to a depth greater than 10 feet above the maximum recorded ground water table. Any existing areas which are below this depth shall be filled with clean earth or sand and well compacted. Where ground water elevation records indicate that it is safe to do so, a variance from the 10-foot distance stated above may be granted as a deviation under Section VIII.

F. Sufficient permanent bench marks 4"x4" wood posts or 2" metal posts or similar markers shall be installed and maintained indicating elevations, as specified in the permit.

VII. DEVIATION FROM REGULATIONS

Permission to deviate from certain requirements as noted herein, will be considered upon written application to the Board of Public Works and may be granted by said Board only after concurrence and written approval is obtained from each of the other departments concerned.

IX. SURVEY BOND

A. That a bond from an approved survey company in the sum of at least $10,000 approved as to form by the City Attorney and payable to the City of Los Angeles shall be filed with the City of Los Angeles, indemnifying the said City against any liability for damages or expense in the event of damage to City-owned or other public facilities or rights by any operation conducted pursuant to the permit, or to defrey expenses or damages in the event that said City or its agencies find it necessary to undertake corrective measures as a result of dumping-operations to protect the public health, safety, and welfare. Further, that such bond shall be continued in full force and effect for a period extending from the effective date of the permit to a date two years subsequent to the termination of the authority granted therein, or for a period of two years subsequent to the date that said operations are wholly and completely abated including the placing of the 3 feet of final cover as required in Section III "F" of these regulations.

B. In the case of applications or renewals where a bond has been deposited as a prerecuisite of zoning variance, a copy of the bond shall be submitted with the application.

X. ENFORCEMENT

The enforcement of the provision or conditions of this permit shall be the responsibility of the Department of Public Works.

Permits may be suspended or revoked by the Board of Public Works because of violation of the provisions of these regulations or other applicable provisions of the Los Angeles Municipal Code or State laws or regulations. Nothing in these regulations shall preclude enforcement of applicable provisions of the Municipal Code or State Law by the duly responsible agencies.

RE: EIR Case No. 91-0377-ZC/GPA
Sunshine Canyon Landfill
Ref. No. SCH No. 92041053
14747 San Fernando Rd., Sylmar

Dear Mr. Plafkin:

Thank you for the opportunity to respond to the draft EIR for the Sunshine Canyon Landfill.

After review of the document it has been found that the project will have no impact on the City of Glendale or its operation. 236

Sincerely,

John W. McKenna
Director of Planning

SUBJECT: Comments on the Sunshine Canyon Landfill Subsequent Environmental Impact Report (SEIR, SCH No. 92041053)

Dear Ms. Paul:

Thank you for allowing us the opportunity to review and comment on the above-referenced SEIR for the proposed expansion of the Sunshine Canyon.

Over the past eight years the City of Santa Clarita has stayed actively involved in the regional solid waste planning process. Initially, our focus was primarily that of opposition to the placement of new landfills at multiple locations adjacent to the City limits. For the past several years, however, a considerable effort has been made to focus on the broader issues of solid waste management. The GBB Report, the UCLA Policy Summit, and other current efforts to focus the concerns of the cities throughout the County have all been undertaken with the goal of providing constructive input into the planning process. We have undertaken our comments on the SEIR document with this, as well as the CEQA Guidelines, in mind. 237

Based on our review and understanding of the Draft SEIR prepared for the Sunshine Canyon Landfill expansion project, we offer the following comments and observations for your consideration in the Final SEIR. 238

1) The SEIR contains numerous references to the proposed Elsmere Canyon Landfill as a 190-million ton facility, located in the Angeles National Forest, having a footprint of 700+ acres and an operational life of from 50 to 100 years. As you may be aware, this iteration of the proposed Elsmere Canyon landfill has been dropped from consideration by the United States Forest Service (USFS), and the County of Los Angeles Regional Planning Department, the regulatory agencies involved in processing the request. 239

PRINTED ON RECYCLED PAPER

Specifically, the Omnibus Parks and Public Lands Management Act of 1996 prohibits the use or trade of land within the Angeles National Forest for use as a landfill facility. The Act was signed into law by President Clinton on November 12, 1997, effectively ending consideration of the 190-million ton proposal by the USFS. The USFS subsequently requested of the property owner, Browning Ferris Industries (BFI), that the case be withdrawn and BFI has complied. County Regional Planning has also requested in writing that the project be withdrawn from consideration, and though BFI has not complied with this request, County Regional Planning staff is no longer actively processing the proposal. Additionally, County senior management staff have publicly stated that Elsmere Canyon will not be developed as a landfill. 240

In light of the above, we would recommend that all references to the development of Elsmere Canyon as a landfill be deleted from the SEIR. 241
Failing that, we request that language be added to the SEIR that the Elsmere Canyon landfill proposal identified in therein is no longer actively under consideration, nor is it at this time a viable or legal landfill development option. 242

2) The proposed expansion project does not include the development of an associated on-site Materials Recovery Facility (MRF) to complement existing recycling and composting activities at the landfill site. Reconsideration should be given to the provision of a MRF at this location insofar as it would assist the City of Los Angeles, and the region, to meet AB 939's mandated diversion goal of 50%, and the City's own adopted goal of 70% diversion. To not implement a MRF at this location appears to be a sorely missed opportunity for both the public and the applicant. 243

3) Our review of the air quality section indicates that the section is difficult to read and is unclear. Impacts are addressed in a number of different ways, rely on studies done at different times and under varying conditions, and generally do not clearly convey information to the lay reader. 244 The air quality impacts of this project exceed components of both state and federal statutes, and this should be clearly stated. 245 Ultimately, the air quality impacts of this project are adverse and unavoidable even after mitigation measures are applied. 246
Additionally, the Health Risk Analysis (Section 4.2.9) set forth on page 4-64 discusses SCAQMD guidelines. Care should be taken to identify whether the Health Risk Analysis undertaken pursuant to SCAQMD standards will also meet those required under the federal Clean Air Act; it is our understanding that the requirements vary between the acceptable levels, parts per million, 247

between the state and federal, with the federal being the less permissive of the two.

This concludes our comments on the Draft SEIR at this time. If you have any questions or concerns, please call me at (805) 294-2522.

Sincerely,

Donald M. Williams
Senior Planner

Dear Mr. Plafkin:

Re: SUNSHINE CANYON LANDFILL SUBSEQUENT ENVIRONMENTAL IMPACT REPORT (SEIR) NO. 91-0377-ZC/GPA

Thank you for giving the Los Angeles Unified School District the opportunity to comment on the SEIR for the Sunshine Canyon Landfill project.

The air quality at three local schools – Van Gogh Street and El Oro Way Elementary Schools, and Robert Frost Middle School – could be affected by the project. Therefore, adequate and feasible mitigation measures must be incorporated into this project to address potential impacts on these schools and reduce those impacts to a level of insignificance. 248

The attached comments from the District's Environmental Health and Safety Branch discuss the air quality impacts and propose mitigation measures to address such impacts. 249

If you need additional information, please call me at (213) 633-8985.

Very truly yours,

Patricia Dean

SUBJECT: Sunshine Canyon Landfill: SEIR

In response to your request to provide comments on the air quality element for above referenced project, the following is provided.

Upon review of the available documentation presented in the Subsequent Environmental Impact Report (SEIR) staff notes that the applicant readily proclaims particulate (PM_{10}) and nitrogen oxide (NO_x) emissions associated with construction of the proposed project would produce "adverse" and "significant" air quality impacts. Operational impacts were also reported to be "adverse" for PM_{10}, NO_x and carbon monoxide (CO). However, staff believes that even with the applicant's admission of the project's significant impacts, their analysis is erroneous in its approach to quantify contaminant values with the use of outdated predictive emission equations and assumptions that favor under prediction. 250

For example, the applicant utilizes soil testing data collected from a site located approximately 10 miles from the proposed project to develop a fractional profile of total suspended particulates (TSP) to particulates ≤ 10 microns (PM_{10}). As such, the value utilized by the applicant was 28.6 percent. Based on this value, a daily PM_{10} generation rate, assuming a water spray application to suppress dust, was estimated to be 158 pounds per day. Nevertheless, the California Air Resources Board (CARB) and South Coast Air Quality Management District (SCAQMD) recommend higher fractional values of 55 and 50 percent, respectively. In addition, the U.S. Environmental Protection Agency, Office of Air Quality Planning and Standards (OAQPS) "strongly recommends" that "site-specific data" be utilized when generating emission estimates with approved predictive emission equations. In the absence of such data, a standard or recognized default value must be used. Therefore, to exemplify the applicant's attempt to under predict particulate generation, use of the 50 percent fractional value will yield a daily emission rate of 303 pounds. As such, the applicant underestimates the daily emission rate by 145 pounds. 251

In addition, the applicant predicts particulate emissions associated with vehicular travel on paved surfaces within the boundary of the landfill will emit approximately 3,333 pounds per day. Assuming a control efficiency of 95 percent for a twice daily water application, the daily generation rate is approximately 167 pounds. Notwithstanding the applicant's approach to quantify particulate generation, they base this estimate on a predictive emission equation that is no longer valid. If one utilizes the current OAQPS emission factor equation and applies the applicant's control efficiency of 95 percent, the 252

emissions generated from truck travel on paved roads within the landfill are predicted to be 275 pounds per day. As a result, the applicant underestimates the daily PM_{10} generation rate by 108 pounds.

However, even with the significant discrepancy in particulate source strength noted above and their admission of the project's adverse affect on local air quality, implementation of proposed mitigation measures will not limit the degradation of air quality and project related impacts remain significant and unavoidable. 253

As result of the project's potential to degrade local air quality, staff is concerned for the health of the students and staff attending schools in proximity of the proposed landfill. To underscore our concern, the South Coast Air Quality Management District reports "Inhalation of particulates may cause coughing, wheezing, and physical discomfort in breathing, and may alter the immune system. Elevation in the level of ambient particulates has been linked to increased mortality, respiratory infections, asthma attacks, and aggravation of pre-existing respiratory and cardiovascular diseases. The results of these conditions include increased hospitalizations, and school and work absences (SCAQMD 1997)." 254

NO_x refers to a mixture of nitric oxide (NO) and nitrogen dioxide (NO2) compounds. However, it is reported that NO reacts rapidly to form NO_2 in and around areas with high NO_x generation rates. Exposure to NO_2 will elicit or alter sensory responses. Impaired pulmonary function, increased incidence of acute respiratory disease and difficulty in breathing for individuals afflicted with bronchitis especially young children have also been documented (SCAQMD 1994). 255

Adverse health effects associated with CO exposure result primarily from its ability to displace oxygen and bind with the hemoglobin in the blood, reducing the capacity of the blood to carry oxygen. Exposure to CO may elicit mild headaches and breathlessness with moderate exercise. Continued exposure may lead to severe headaches, irritability, impaired judgment and memory, and rapid onset of fatigue (Cal/EPA, 1995). 256

As a result, contaminant emissions generated from construction and operational activities, as presented in the SEIR, are considered unacceptable and necessitate appropriate mitigation for students and staff who work and/or attend class at the neighboring Van Gogh Street, El Oro Way and Robert Frost Middle school sites. 257

Unless the applicant can quantify through the application of revised emission estimates and associated dispersion modeling that project related emissions will not contribute to an existing air quality violation or expose sensitive individuals to substantial pollutant concentrations, the applicant must provide effective offsite controls to minimize contaminant infiltration within occupied building structures. 258

Offsite controls shall mean the installation of local air purification systems which exhibit a control efficiency of not less than 95 percent for particulates (≤ 10 microns) 259

gases and vapors. Additionally, outdoor ancillary structures used by students and staff during lunch and recess (i.e., tables and benches) shall receive periodic cleaning to minimize particulate deposition and subsequent reentrainment. 260

Please advise as to the disposition of this memorandum and subsequent response by the applicant. I can be reached at (213) 743-5086 should you have any questions or need additional information. 261

:bp

CITY OF LOS ANGELES
DEPARTMENT OF CITY PLANNING
Environmental Review Section

Date: July 25, 1997

TO: Owners of Property and Occupants Within a 2-mile radius

NOTICE OF COMPLETION AND AVAILABILITY OF
DRAFT SUBSEQUENT ENVIRONMENTAL IMPACT REPORT NO. 91-0377-ZC/GPA

SITE LOCATION: 14747 San Fernando Road, Sylmar, CA 91342

A development project has been proposed for this site, for which the captioned draft subsequent environmental impact report has been prepared. The project is described as: Consisting of the development, operation, maintenance, and monitoring of a Class III, nonhazardous solid waste landfill (herein, City/Country Landfill on proposed project). A portion of the proposed City/County Landfill footprint is located on ±194 acres within the City portion of Sunshine Canyon and provides an estimated net airspace disposal capacity of 55 million tons within the City.

Initially, the City and County landfill areas would be operated separately and provide an average daily capacity of 5,000 tons per day (tpd) in the City and 6,000 tpd in the County. However, within 18 to 24 months following the commencement of landfilling operations in the City, the City and County landfilling operations would be subsequently combined into a single landfill operation and at one working face area. This would allow for an average waste intake rate of 11,000 tpd. The combined development of land within both jurisdictions would result in one landfill footprint being constructed in Sunshine Canyon. The landfill footprint configuration would ultimately encompass ±451 acres.

Anticipated significant effects on the environment are: Earth Resources, Air Quality, Surface and Groundwater, Biological Resources, Noise, Light and Glare, Land Use, Natural Resources, Risk of Upset, Population, Housing, Right-of-Way and Access, Transportation and Circulation, Public Services, Energy Conservation, Utilities, Safety, Aesthetics/View and Cultural Resources

If you wish to review a copy of the draft subsequent environmental impact report (EIR) or the documents referenced in the DEIR, you may do so at 221 N. Figueroa Street, Room 1500, Los Angeles. Copies of the DEIR are also at the following locations:

re: Report No. 91-0377-ZC/GPA

Hadar Plafkin
City Planner

We have been residents at our present location for nearly 30 years. Throughout this period, we and our neighbors have been in a nearly constant struggle with government officials and landfill proponents to control and or desist unsavory operations in Sunshine Canyon.

When the Santa Ana winds occur, we have been inundated with debris and leavings blown from the dump. The most disastrous event was a firestorm in this area, which occurred a few years ago. Although blame was never publicly placed, the fire started from the area of the dump. 263

Therefore, in the most rigorous way, we vehemently oppose this proposed landfill project. 264

Which beckons a much broader issue: Why is it that citizens,such as ourselves, and not appointed and elected officials bear the brunt of defense against such unsafe environmental proposals?

Sincerely

Joycelyn Turner

Re: Proposed Sunshine Canyon Landfill Site

Dear Mr. Plafkin,

Anheuser-Busch Sales and Services of Sylmar recently received a letter from your office notifying us of a proposed landfill site within two miles of our facility. The letter further indicated that a copy of the Environmental Impact Report (EIR) would be available for review at a variety of public library locations in the Los Angeles area. In a telephone conversation with you today you indicated that the EIR contains multiple volumes but that a summary document of this EIR may become available. I would like to request a copy of this summary document should it become available. You may mail the summary document to the following address: 265

Anheuser-Busch Companies, Inc.

221 NO. FIGUEROA STREET, ROOM 1500
LOS ANGELES, CALIFORNIA 90012

CONTACT PERSON: HADAR PLAFKIN

I have received a letter dated July 25, 1997 entitled, "Notice of Completion and Availability of Draft Subsequent Environmental Impact Report No 91-0377-ZC/GPA.

I am an owner of property within the 2-mile radius of the Site Location: 14747 San Fernando Road, Sylmar, CA 91342

These are my comments.

I have lived on Daryl Avenue, Granada Hills, CA for 29 years.

There is not enough space or energy to express my feelings regarding this project which has been a source of great concern for those of us who live here. This project would not be remotely considered as a landfill if the powers that be would honestly come out and look at the facts and research the environmental impacts such a mega-dump will have on so many people for such a long, long period of time as well as quite possibly contaminate the water supply of the City of Los Angeles. 266

I hope this situation is give the most grave consideration as it is truly over-whelming -- the consequences. 267

Now, we in Granada Hills have been able to re-construct our homes and business' after the earthquate three + years ago, we were able to cope with the recession of the past few years, the fires which have plauged us here in the hills in the past, but this mega-dump is something over which we have no control -- such a project is ad infinitum. 268 The destruction of the mountains to create it -- can't reconstruct a mountain, 269 can't control waste liquification below the ground from the garbage and filth, 270 can't control the stench as the trash is deposited into a beautiful neighborhood which has long been established here. 271

RECEIVED
CITY OF LOS ANGELES
AUG - 7 1997
ENVIRONMENTAL UNIT

When President Clinton gave his inaugural address, and I am quoting him, he said at one point in his speech, "Our children should not have to play at the edge of garbage dumps in our cities but in parks. It is my desire to accomplish this for our American children during my administration."

This Sunshine Canyon Dump is "0" feet from O'Melveney Park, the largest park in Los Angeles, second only to Griffith Park. It is also adjacent to Bee Canyon Park where only recently playground equipment has been installed for pre-school children. We have zero grafetti up here, almost never hear a police siren, have pride of ownership and take care of our neighborhoods and each other. 272

The Van Gogh Elementary School, which was totally demolished in the earthquake has just been rebuilt and will open for the Fall session the cost of which is unknown to me. It is approximately 8 to 10 blocks from the edge of the landfill property. 273

A footnote:

August 1, 1997

Tonight on the 5:00 p.m. Channel 4 news with Paul Moyer, it was reported a geological survey has determined that Granada Hills, Santa Clarita, and other Northern areas of the San Fernando Valley are prone to eqrthquakes previously not considered because of a condition known as liquification of the soil. Hal Fischman on Channel 5 at 10:25 gave a similar report, however more extensive and maps were shown on the TV which I am sure are available to the City of Los Angeles Environmental people. We also know that waste and garbage is prone to liquification after a period of time after it is under ground. 274

We all know our lives, as they are controlled by this imminent project, are held in the hands of a few men - the County Board of Supervisors and the Los Angeles City Council. It is time again for us here in this lovely area (this 2-mile radius of the Sunshine Canyon Landfill) to stand up and be counted. 275

Write to your City Council, The Board of Supervisors and to this Department of City Planning.

Respectfully.

Re: 91-0377-ZC/GPA

Dear City Planner:

Please, please do no allow the site at 14747 San Fernando Road, Sylmar, CA 91342 to be used as a landfill. The Sunshine Canyon landfill is already polluting our community and we need less, not more, dumping of debris, etc. in our community. **277**

My husband and I moved out here with our children about 20 years ago. Prior to moving here none of us had any allergies. After a year, we were all getting allergies. At first we did not know why, but speculated it was the Sunshine dump. Now we are positive it was caused by the dump because after it closed, our allergies seemed to clear-up. (Not right away, but a year or two later.) **278**

Also, there is a continuous amount of debris and dust in the air. Again, when the dump was in operation, the inside of our home, our garage, and even our cars were always dusty, even shortly after cleaning. When the dump closed, there was a very noticeable difference. The inside of our home did not get as dusty and the cars stayed cleaner longer. Likewise when the dump went back into operation, everything got dusty again. **279**

Of course there are other environmental factors of concern to us. There is always the problem of leakage and contamination of the soil and underground water, which can cause chronic diseases if undetected. It sometimes takes years before one of these diseases develop, and then it is too late. **280** Of course, there's the known pollution from dump trunks coming into the dump area, too. **281**

Finally, it is just not fair that the "Valley" (*Our location in the valley has been singled out to receive trash for a period of time way in excess of that initially agreed to when dumping first began*) has to be the receptacle for all of Los Angeles' trash. Los Angeles is a large county and there are other areas which should be used for dumping. In fact, each supervisial district should be responsible for its own trash. **282**

Therefore, I respectfully ask that you deny the project as described on your notice 91-0377-ZC/GPA.

Respectfully Submitted,,

Sharon E. Yackey

Dear Hadar,

In reference to the development project that has been proposed to be situated within the City portion of Sunshine Canyon. I am vehemently opposed to the idea of developing, operating and maintaining, and monitoring a Class III, nonhazardous solid waste landfill within or near the confines of populated domains. The anticipated effects on the environment are not in my personal best interest, my family's or my neighbors'. The negative effects are far more numerous than the positive impact that it could have for public use. I would suggest that a project with such anticipated effects on the environment and society be relocated to an area far removed from any areas where people will be residing; even if relocation means increased fees to transport the nonhazardous solid waste. 283

Re: Sunshine Landfill Expansion Draft Subsequent Environmental Impact Report #91-0377-ZC/GPA

Dear Mr. Plafkin:

We are a California non-profit organization made up of civic groups homeowners associations and environmental organizations throughout Los Angeles County. We have been active participants in solid waste issues in Los Angeles County since 1990.

Our organization commented extensively on the Sunshine Landfill Expansion during the County process. We were therefore surprised not to receive a copy of the DEIR for the City expansion. We have several members who are interested in different aspects of the project and therefore request a copy of the DEIR so that we may photocopy and divide it between our members. 284

We hope you will send us this document at the as soon as possible. Thank-you in advance for your help.

Sincerely,

Lynne A. Plambeck

Re: Comments on EIR No. 91-0377-ZC/GPA, A Class III Landfill in Sunshine Canyon

Dear Mr. Plafkin,

I am writing in response to section 4.2 (Air Quality) which describes the weather patterns and predicted airborne contaminant dispersion as a result of the landfill operation in Sunshine Canyon.

The EIR describing the windflow patterns is pathetically poor science. Its tries to state that mild winds from the South occur year-round, blowing any possible air contamination into the Northern canyons and away from the Los Angeles basin. This is patently untrue. **285**

I have attached an article I published in the Journal of Applied Meteorology which describes Winter wind conditions in the San Fernando Valley (SFV) as those winds blow through the Newhall Pass (and over Sunshine Canyon). This report, like all the others describing winds in the SFV, were not mentioned in the EIR. **286**

The basis of my complaint is the following:
The Santa Ana winds flow through three mountain passes from the High Desert into the Los Angeles Basin. They are the: Newhall Pass, Santa Ana Canyon, and Cajon Pass. The duration and extent of these winds is so great within the Newhall Pass, I conducted a tree study sponsored by California State University, Northridge showing the amount of tree deformation due to the winds, and correlated that with spot windvane anemometer observations throughout the pass and the mountains on either side of the pass. A reprint of that article is enclosed. **287**

Winds on the West side of the pass are much stronger that the East side. I have clocked winds to 65 mph with sustained winds of 40 mph on the East face of Oat Mountain (just West of the dump) on many occasions. The winds occur prevalently from October through May. Taking the 6 event number quoted in the EIR and multiplying by 10 for a total of 60 events per year is the most probable number reflecting what actually occurs there.

The wind blows from NW to NE. Strong Santa Ana events dominate from the NE covering the Central and Western SFV. Some of that wind blows down the canyons of Oat Mountain. Most of these canyons are oriented along a NW-SE axis, blowing a large component of winds from the NW and down the foothills of Oat Mountain in the Central SFV. Unfortunately for Sunshine Canyon whose top dumping zone will be at 2100 feet, this wind sheer occur along the canyons of Oat Mountain at an elevation of 1500 feet. **288**

What occurs during the Winter half of the year is a fan dispersion of enormous force that focuses at the Northern apex of the SFV, and disperses into the entire valley. **289**

↓

Unless of course, the winds are mild, and there is a strong inversion. In that case, the winds skip over the inversion much like tossing a pebble onto a lake, where the winds extend as far as Catalina, kicking up large ocean swells there.

One of the largest canyons in the Oat Mountain area is Bee Canyon. This canyon diverts a significant component of the Santa Ana's, and funnels them into Granada Hills and the Van Norman Lakes. These lakes provide a significant part of the water for Los Angeles, and have the unique distinction of being post-processing reservoirs. That is, the water from the California Aqueduct is treated then poured into the lakes. From there is goes directly into the drinking water supply. **290**

These observations occurred over a decade before the Sunshine EIR. It is attached for your edification. The wind rose presented in figure 4.2-2 should either be labeled "Summer Wind rose for the SFV", or be thrown out altogether as a complete misrepresentation of the annual winds of the SFV. **291**

One interesting item was not mentioned in the EIR. The Santa Clarita area, including the Newhall Pass has a large accumulation of oil wells and oil processing facilities. Many sites have gas flaring towers to burn off the natural gas collected with the oil pumping. It is surprising that the EIR never considered what will happen in Santa Ana events when Northerly breezes from these fields and their NOx and SOx contaminants mix with dump gases. **292**

In my review of the literature, there was an interesting report about SFV sea breezes. Your report shows only breezes coming up from Burbank which occur during Catalina eddy conditions. But what about other times? One of the most common sea breezes in the SFV is a Westerly breeze that originates in the Oxnard plain, blowing West over the Simi Hills, and into the SFV. This creates a sea breeze front with mixing and strong vertical currents in its path. The vertical rise is large enough that a line of clouds oriented North to South periodically demarcates the front. The sea breeze moves East, stagnating against the San Gabriel mountains of the Eastern SFV. **293**

This produces a stagnation effect that serves to trap pollution in the SFV. Unlike the "it will dump out of the valley at Burbank and go away" conclusion of the EIR, repeated strong onshore flows in Summer will serve to accumulate pollution in the Central and Eastern SFV. Combined the Summer diurnal land breeze ejecting dump gases down the Canyons of Oat Mountain and the Newhall Pass, there is much less circulation and cleansing of SFV air than the report would indicate.

Mitigation:
The Santa Ana winds are prevalent and strong in the Western Newhall Pass during Winter. The only mitigation feasible (short of closing the dump) is to monitor the winds along the ridge defining the Western part of the dump. When winds exceed some threshold (say, sustained for some interval over 25 mph), dumping should occur for the next 24 hours at lower elevations. **294**

Santa Ana Windflow in the Newhall Pass as Determined by an Analysis of Tree Deformation

DONALD T. KASPER[1]

Department of Geography, California State University, Northridge 91324

(Manuscript received 6 March 1980, in final form 2 July 1981)

ABSTRACT

A tree deformation study was conducted in a suburban area of the Newhall Pass (located to the north of Los Angeles, California) to determine the direction and intensity of the Santa Ana windflow. Trees were used to provide the large data base necessary to study the windflow in rugged terrain in an area that is very vulnerable to the fire hazard presented by these winds.

To obtain a large data base, the study involved the use of several tree species. Comparison of the wind-direction data obtained from the trees correlates very closely with windvane data obtained in the study area. In measuring the intensity of the winds, a statistical deformation index was devised that is not affected by differing species response to the wind. This index is based upon the total number of trees per unit area that are deformed. It transforms the study of wind intensity—as reflected by the trees—from a largely qualitative judgement of the degree of tree deformation to a quantitative statistic.

With a careful consideration of non-wind effects which can deform the trees, studies of this type are very inexpensive and easy to conduct, providing an accurate climatological wind record as an adjunct to long-term meteorological data, especially in data-sparse regions.

1. Introduction

The Newhall Pass is one of the few passes in the Transverse Mountain range system that allows the flow of the Santa Ana winds to continue from the high desert into the Los Angeles basin. Unlike the other passes (Cajon, San Gorgonio and Santa Ana), the Newhall pass has not yet been studied in detail.

A 30 km^2 area on the south side of the pass was chosen as the study area. Three major canyons incise the relatively rugged terrrain—Limekiln, Aliso and Bee canyons. To establish a network of wind stations in this terrain would be both difficult and costly to provide the density of wind stations required to ascertain the microtopographical wind characteristics. Trees, on the other hand, can provide a very dense data base from which the details of windflow in the area can be determined. A total of 465 trees were studied to provide a detailed reconstruction of the windflow.

The city of Los Angeles abuts against the hills in the study area. This suburban perimeter is the most sensitive to the Santa Anas that blow through the pass; the fire hazard associated with the Santa Anas is well known (Sommers, 1978; Fosberg *et al.*, 1966; Edinger *et al.*, 1964). Since fires have burned on several occasions to the edge of the suburban homes in this study area, detailed documentation of the Santa Ana intensity and direction is certainly worthwhile.

2. Determining the wind type affecting the trees

In the study of tree deformation, past studies have followed a consistent sequence of steps. The principal step is to determine what wind is deforming the trees. Only the most detrimental winds—those that have damaged the trees to an observable extent—can be measured. It is most often not the mean annual wind. Along the coast, the trees will be deformed by salt-laden winds blowing off the ocean (Davies, 1810; Edwards and Claxton, 1964; Kayane, 1969; Thomas, 1973). In regimes with winter snows, the trees will be affected by winds that blow the snow and glaze droplets (Lawrence, 1939; Yoshino, 1964, 1975) or the trees may be affected by summertime winds that damage new growth (Putnam, 1948). Yoshino (1975) emphasized these types of tree response in the following classification scheme:

I: Branches are bent drastically to the leeward of the tree by the prevailing winds during their growing period. This type consists of conifers and poplars.

II: Branches on the windward side of the tree are severed by the effects of winter winds carrying snow or frozen rain. This type consists only of conifers as far as is known.

III: Trunks and branches both deformed drastically by the prevailing wind during their growing

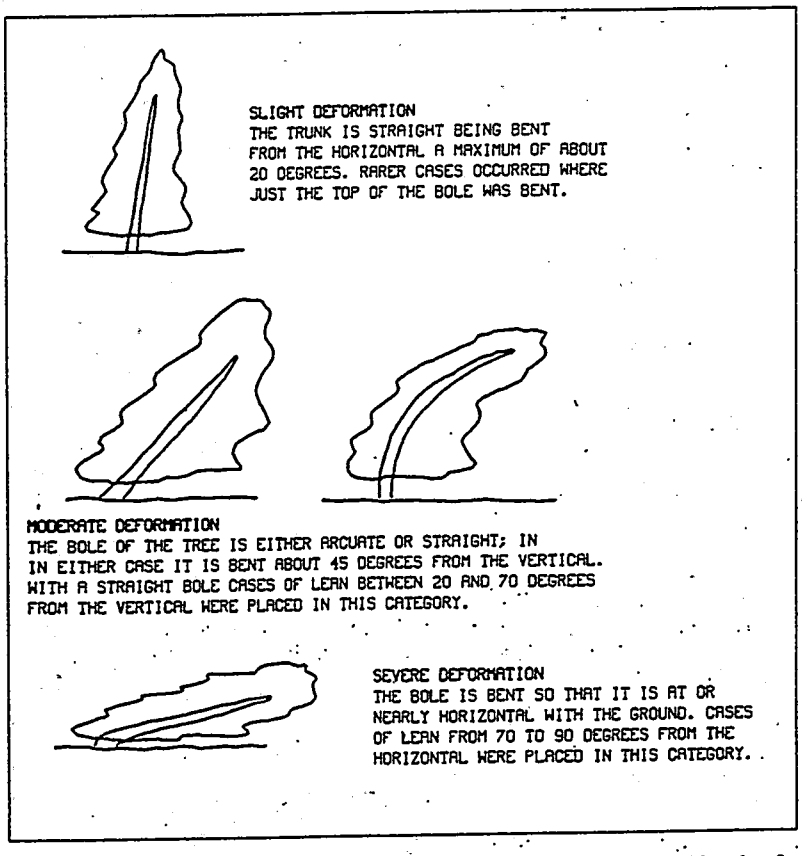

FIG. 1. Pictoral sketches and the accompanying definitions for the three levels of deformed trees comprising the deformation-intensity scale.

season. This type consists of deciduous and evergreen broadleaf trees. They are often found in coastal areas.

IV: Trunks are deformed due to occasional strong winds. The shape of the canopy is symmetrical.

This study consists of the only deformation type (according to Yoshino) that has yet to be studied—deformation type IV. The only intense winds that occur in the area are the Santa Ana winds. The Santa Anas blow almost exclusively from September to June of each year (with peak intensities in fall and spring). They exert a strong and dessicating force on the trees. During the subsequent growing season new growth sprouts unimpeded. The result is a deformed tree bole with a symmetrical and largely unaffected canopy.

There are two aspects of the winds that can be obtained from the deformed trees. The direction the tree is leaning indicates the direction the wind blew from in deforming it. Direction of lean was measured with a Lensatic compass to the nearest 5° interval. An indication of wind intensity can be gauged by establishing a scale of deformation. Fig. 1 depicts the scale devised for this study. Fig. 2 shows more complex variations of the scale which occur in the field. Photos 1–4 show actual field examples.

3. Comparisons with meteorological data

Tree data are often coupled with some meteorological data from weather stations in the study area. Such data serve as a secondary verification of the tree results. A number of locales were selected in the study area where spot windvane data were recorded during the winter of 1976–77. The idea was to have a large number of sample sites throughout the study area so that a representative wind sample would be derived. The distribution of windflow for the entire area was determined with the results compared to the distribution indicated by the trees. This provides good evidence as to whether the trees reflect the main Santa Ana flow.

Fig. 3 exhibits a number of points that have been discussed so far. The figure shows the distribution of each level of deformation and the windvane results in a cumulative graph. The following conclusions can be made from the graph:

• The graph is a normal distribution. To emphasize this, the data have been plotted on probability paper (it has the characteristic that a normal distribution will plot as a straight line). The mean direction of Santa Anas is 360° with 80% of all winds in the area blowing from between NW and NE.

• The different levels of deformation correspond very closely indicating that each is a response to the same windflow.

• The windvane and tree deformation results are almost identical; the trees are accurately reflecting the regional windflow.

• The windvane data represent a graphing of only Santa Ana winds. The close correlation of the windvane curve and the tree deformation curves shows that the trees studied are only deformed by Santa winds.

4. Non-wind effects acting on the trees

The primary source of error in a tree deformation study are non-wind effects that induce deformation of the trees. It is the most important aspect of any tree deformation study, but has received little attention in the literature. Since this is a suburban study, errors due to man-made and natural non-wind effects must be considered.

The climate is quite mild in that trees in the study area are not affected by ice, snow or glaze droplets (it never snows in the area), or salt spray (the study area is 30 km from the ocean). Nor were the rarer effects of flood, avalanche, hail, cold, lightning or fire observed. Drought is not a problem for these trees grew on homeowners' property with all trees appearing adequately watered.

Trees exhibiting any of the following characteristics were excluded from use in this study:

• Newly planted trees, that is, those with trunks that are less than 3 inches in diameter. The trunks are often tall and unable to support the canopy causing them to lean over.

• Guy-wired or staked trees (especially newly planted trees). They do not show the accurate degree of deformation of the correct azimuth of lean. Acceptable are large trees with tiny stakes that are not tied to the trees, being old remnants.

• Any tree near other trees that have since been cut down that could have influenced the growth of the tree in question. This is evidenced by the old stumps that are often not removed.

• Scars on the trunk, especially on the side opposite the direction of tree lean, indicating that the tree is leaning due to being hit by an auto or otherwise damaged.

• Wilting of a tree due to lack of water. The needles and leaves are characteristically wilted.

• Subsidence of the soil near sprinkler system pipes inducing tree lean. This is often associated with a depression of the soil adjacent to the pipe, with the tree leaning into the depression.

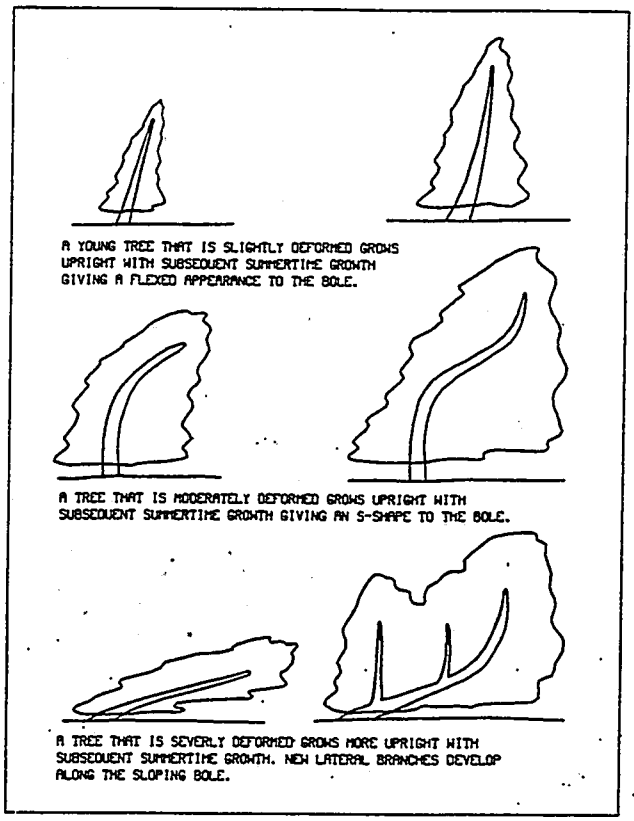

FIG. 2. Examples of more complex variations of the deformation–intensity scale that occur in the field are depicted.

• Trees with undermined or exposed roots. The roots are exposed due to erosion or windthrow (trees uprooted partially and leaning due to a single, intense windstorm).

• Trees planted in non-compacted earth fill, especially trees planted in soil filled behind brick embankments.

• Soil creep and landsliding. These trees are on noticeable slopes with the trees leaning downhill.

• Groves of trees, since they could be deformed by winds altered by the grove itself.

• Trees sheltered from winds blowing from any direction. This includes sheltering by other trees and by the local terrain. Sheltering by houses is by far the most common—probably why far less trees exhibit deformation in the area than would be expected in a natural forest setting.

• Pruning, inducing irregular trunk growth and artificial bole curvature. Trees arching over with evidence of old branch or prior tree shoot stubs at the point of curvature.

• Reaching for sunlight by growing out from houses or other trees.

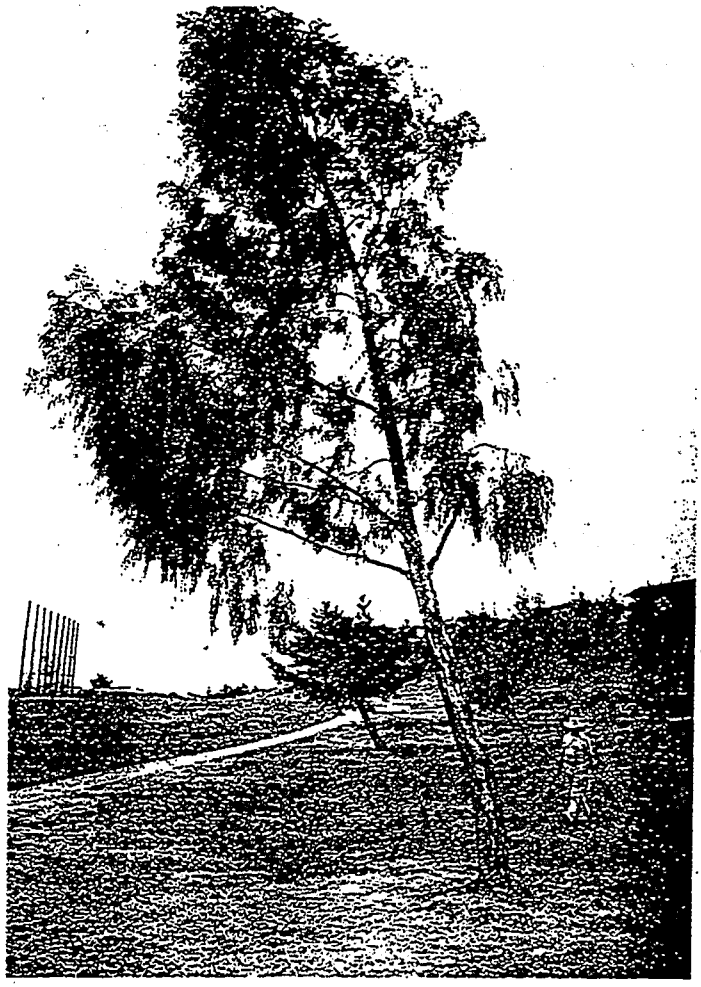

PHOTO 1. A eucalyptus tree exhibiting slight deformation. Though this tree shows a tendency for more foliage to occur to the lee, this is not found with the three trees in the immediate background. Foliage assymetry is not as consistent a characteristic of tree deformation intensity (for this area) as is the curvature of the tree bole.

• Trenches, streetwork or other digging that could have damaged the roots or softened the soil so that the tree collapsed into the area of soft soil.

• Trees that bend along the bole length in more than one direction. This is often a result of several prior times of tree guy-wiring and/or pruning.

• This study selected for trees with straight boles for at least one foot from ground-level then leaning over. This minimizes the possibility of recording one-time windthrow events rather than long-term wind deformation effects. Trees with straight boles from the ground up were scrutinized for evidence of windthrow. The dislodging of the roots produces a mounding of the soil upwind with the near-surface roots becoming exposed in subsequent years.

Fig. 4 shows a frequently observed pattern of man-induced deformation. Several effects on the trees that are difficult or impossible to determine are changes in soil fertility, differences in soil type, retarded root growth, disease or insect pests, effects of tree age, summertime heat stress, air pollution and injurious chemicals.

One final error source needs to be considered. Most studies have used only one species of tree to use as a wind indicator. The logic involves the concept of a "species effect". The concept is that since different species have different degrees of resistance to the wind, the use of a scale of tree deformation must be a unispecies study. This recently was re-emphasized by Wade and Hewson (1979).

This study is a multispecies study. About 51% of the trees studied were pines, 23% were eucalyptus and 12% evergreen pear (*Pyrus kawakami*). The remainder consists of lesser percentages of other tree types. In a suburban setting the tree type will not be homogenous. To have a large data base a multispecies study is necessary. The primary ques-

PHOTO 2. Two large eucalyptus trees exhibiting moderate deformation. Note the arcuate bole of the tree on the right. The tree on the left has the same arcuate trunk, but this is partially obscured by more recent growth directed more upright.

PHOTO 3. A pine with a straight trunk classified as moderate deformation.

PHOTO 4. A pine exhibiting severe deformation. The bole extends straight up for about 1 ft, then bends at an angle of 80° from the vertical. This emphasizes the violent nature and power of the worst Santa Ana windstorms.

tion considered here is the following: Are the other errors so great that the species effect need even be considered? Is the species effect a minor error?

With regards to the direction of tree lean, a species effect is not evidenced. Fig. 5 is a cumulative graph of two groups and one species of tree: pines, euca-

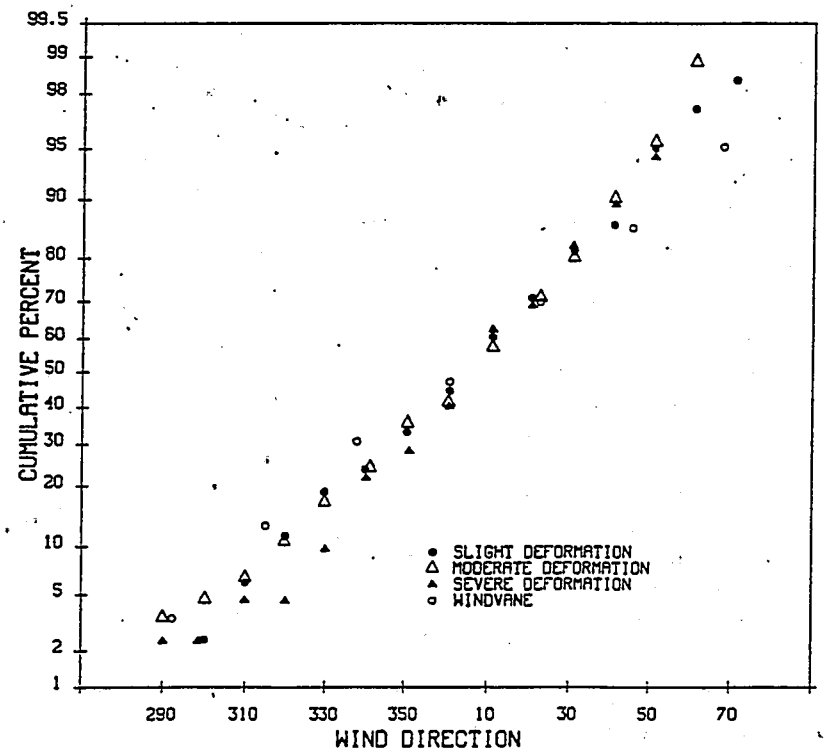

FIG. 3. A comparison of the levels of slight, moderate and severe deformation as compared to the windvane results. The close relationship between the tree and windvane results is emphasized by plotting the data on probability paper (which has the effect that a normal distribution plots as a straight line).

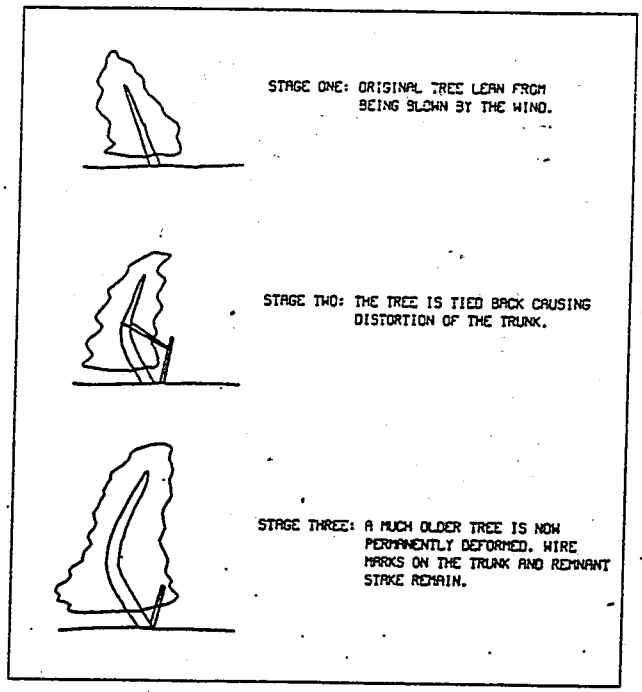

FIG. 4. Man-induced effects considerably alter the appearance of the trees. Shown here is a common sequence of events that produces an unnatural curvature of the tree. As these suburban trees become more deformed by the wind they are concurrently more apt to be altered by man in some way.

lyptus and the tree *Pyrus kawakami*. The distribution of each is graphed along with the windvane results. These groups compare closely to each other and the windvane distribution. The distributions are identical to those of Fig. 3 (where all types of trees were included together). This shows quite clearly that more than one species of tree can be used in studying wind direction.

5. Pattern of windflow in the study area

Testing the magnitude of tree deformation for evidence of a species effect is much harder though two lines of evidence cast doubt on any strong species effect in the study area. If a species effect was pronounced, it would be expected that when mapped, the boundaries separating the magnitudes of deformation would correspond to different tree types. Regions of severe deformation would exist only where pines are found, for example. The occurrence of pine and eucalyptus trees are distributed throughout the study area with no evidence of such an effect observed.

In Fig. 6 the distribution of the direction and intensity of tree deformation in the study area has been mapped. The pattern corresponds not to one of species differences, but rather, strictly topographical effects are noted. In the west and central parts of the study area the pattern is the simplest. The area of Horse ravine, in the direct lee of the Santa Susana mountains which rise to 3000 ft to the immediate north is an area of slight deformation except for the western portion which is affected by winds coming down Limekiln Canyon. The area titled Porter Ranch golf course is affected almost solely by NNE winds with Limekiln Canyon winds having a minimal effect.

The boundary of moderate deformation (called the moderate deformation line) follows the 1100 ft contour up to the southern edge of Bull Canyon. This is the elevation at which the canyons and rugged terrain give way to the flatlands of the San Fernando Valley. The trees indicate a merging of the canyon winds with the NNE winds—the NNE winds dominating. Since these canyon winds do not extend into the flatlands where the NNE winds dominate, the canyon winds are not regarded as being as strong. It would be hard for Aliso and Limekiln canyons to direct much of the Santa Ana winds considering that their origins are downslope and to the lee of the Santa Susana mountain ridge so are laregly sheltered from the main Santa Ana flow. The moderate deformation line is believed to be a result of more intense winds occurring in the hills of the western and northern part of the study area. Note the dominance of the NNE winds with little canyon flow discernible there.

North and South Knollwood ravines contain the Knollwood golf course, being the sites of severe deformation in the eastern part of the study area. On the western edges of these two ravines, low north–south oriented ridges occur that block the

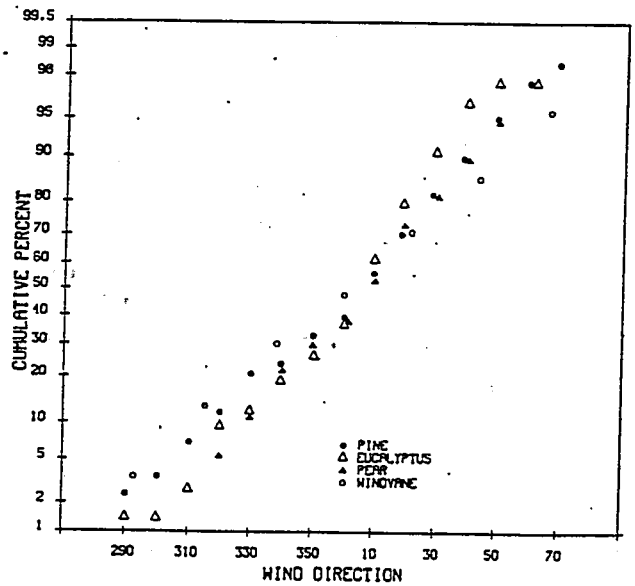

FIG. 5. A comparison of three tree types and the windvane results. The close relationship between the tree types and the windvane results is emphasized by plotting the data on probability paper (which has the effect that a normal distribution plots as a straight line).

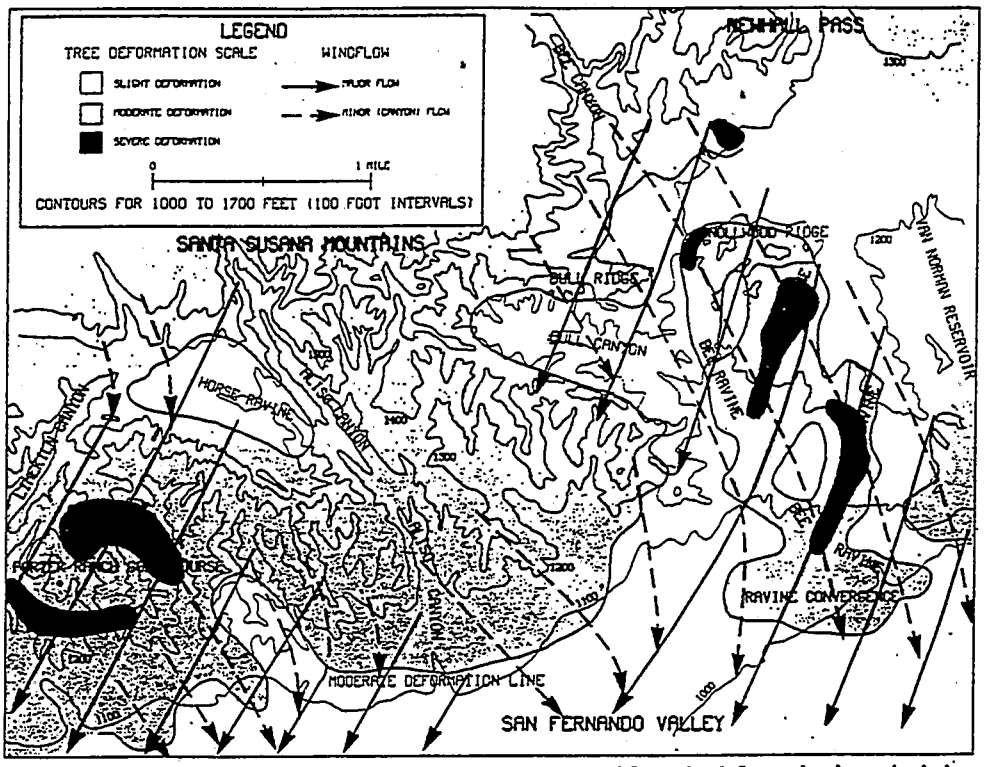

FIG. 6. Relative wind intensity and direction of windflow derived from the deformation intensity index and the direction of tree lean. This map is based on the interpretation of 465 trees for this area.

NNE flow. As a result, areas of slight deformation occur in their lee.

Bee Canyon is different than Aliso and Limekiln canyons. Bee Canyon is situated in the western part of the Newhall Pass (in the northeastern part of the study area). It is the most prominent canyon in the pass. As expected, a strong flow coming down the canyon (and its southern extension called Bee Ravine) is indicated by both the pattern of tree deformation and the direction of tree lean. This flow

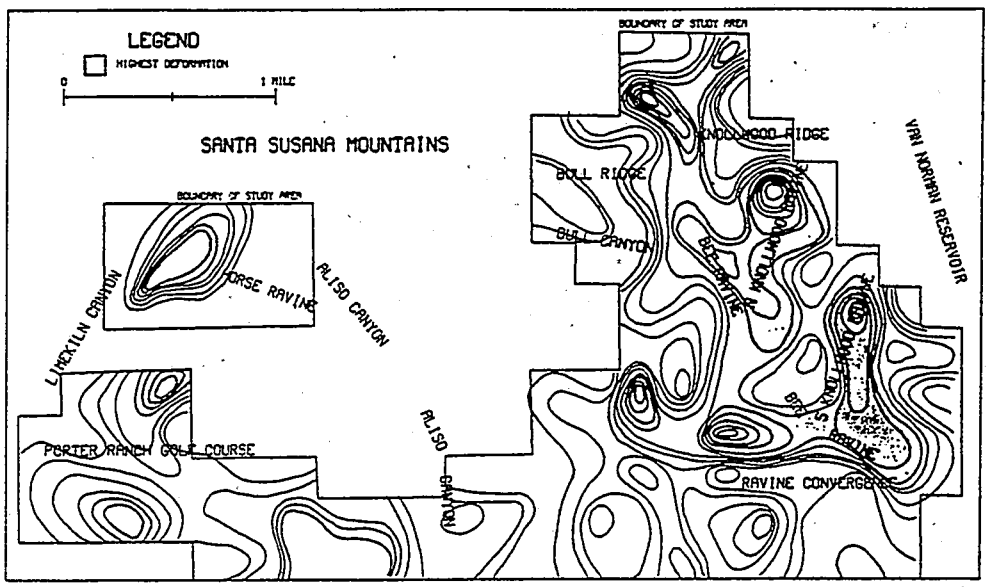

FIG. 7. Contour map of relative wind intensity derived from the statistical deformation index. Though its basis is different than the deformation–intensity index, the results are quite similar (see Fig. 6).

hits Bull and Knollwood ridges causing greater deformation there than adjacent areas. Little wind occurs in the lee of Bull Ridge or the ravine to the south and east of the mouth of Bee Canyon. This NW (canyon) flow extends no further than the ravine convergence area where the main Santa Ana flow dominates.

6. An alternate deformation intensity index

It could logically be expected that areas of higher wind speeds would exhibit not only trees of greater deformation intensity but also that more trees per unit area would be affected. No previous study has used this index primarily because of the small number of trees that have generally been sampled. This type of statistical deformation index has several advantages over the use of a deformation-intensity type of index especially with regards to suburban studies:

- Half of all the trees studied occurred in parking strips and yet virtually none of the severely deformed trees were found there. While the size distribution of slight and moderately deformed trees are quite similar with 59% of slight and 51% of moderately deformed trees being 3–10 inches in diameter, only 24% of severely deformed trees are in this size range. Apparently, small and severely deformed trees are greatly pruned or removed. This induces a bias toward areas where the trees are less likely to be removed such as parks, golf courses and the front yards of homes. The statistical deformation index, including all levels of deformation, will eliminate this effect since trees of slight and moderate deformation are frequently found in parking strips.
- A deformation scale does not have to be devised. A major component of deformation-intensity type indices is the climatic effects acting upon the trees. Since each study area has different climatic effects dominating, previously devised deformation scales cannot be applied to new study areas without careful research and consideration. The statistical deformation index does not greatly depend upon the interpretation of single trees (reflecting climatic effects). A minimization of climatic influence should make tree deformation results between different study areas more readily comparable.
- The index minimizes the influence from any species effect. Any tree deformed above a low threshold (reflected as slight deformation) will be included in the index. This also provides portability of the index to other areas with different tree types.
- In allowing more than one species to be studied, a much larger data base is available to study the windflow.
- Problems of where to draw the boundaries of the various levels of deformation do not arise. The researcher does not have to rely on his judgement as where to exactly draw boundaries in areas with little data.
- It takes the study of tree deformation from a largely qualitative deformation scale to a quantitative statistic. A contour map can be drawn from the statistical deformation index results.
- Finer resolution of deformation intensity is available. Far more contour levels are available compared to the three grades of deformation.
- The new index minimizes the influence of single trees, especially in areas with few trees. This will concurrently minimize the influence of erroneously identified trees.

A map of the study area was marked off into grid cells with the total number of deformed trees being counted for each. From this, the contours were drawn. Fig. 7 shows deformation in the study area using this index. Despite the different nature of this index from the deformation-intensity index, the patterns of deformation are quite similar. Note especially the lack of any indication of strong canyon flow out of Aliso Canyon. Also, the ravine convergence area is more clearly delineated by the index. As a result of the similarity of these two indices, it appears that the species effect is not a significant source of error operating here.

7. Conclusions

A total of 465 trees were studied in a 30 km² area of the south side of the Newhall Pass to study the direction and intensity of the Santa Ana windflow as it leaves the brushland to the north and abuts against the suburban area of the city of Los Angeles. This large sampling was taken to see if the trees could provide a detailed reconstruction of these winds as they blow down the ravines and over the ridges in rugged terrain.

Rather than duplicate the methodology of past studies which have generally compared single station wind data to a surrounding region (often with mixed results) it was decided to use a portable windvane to sample the winds at a number of locales in the study area. Comparison of the windvane data to the wind direction indicated by lean of the trees showed a very close correlation—the trees accurately indicate the direction of the Santa Ana windflow in the area.

To study wind intensity in the study area, two indices were devised. First, a deformation scale was established similar to previous studies which have been conducted. Additionally, a new deformation-intensity index was developed based on the total number of trees per unit area that were deformed. This new index is superior to that it does not rely upon a qualitative judgement of the extent of deformation for a tree.

The study placed considerable emphasis on discerning wind from non-wind effects. An analysis of non-wind effects is one of the most important aspects of any tree study. As a suburban study, both natural and man-made effects were considered.

For small-scale studies involving Santa Ana winds, trees can provide a large data base at very low cost. They are climatological indicators of very long-term wind effects. Tree deformation data act as a useful adjunct to standard meteorological data in providing a more detailed analysis of the winds being studied.

Acknowledgments. I wish to thank Dr. Arnold Court, professor of Climatology at the Geography department of California State University at Northridge for his help with the methodologies and instrumentation used in the windvane portion of the study. Special thanks to Mr. Donald L. Kasper for his help in studying the trees and helpful comments on the phenomena observed and to Paul Kinmond of Union Oil Company for his help in generating the figures for this article using the corporate computer graphics system.

RE: File # 91-0377-2C/GPA (Letter Copy Enclosed)

I have been to a library branch to view the available documents on the Sunshine Canyon Landfill. I counted 39 volumes. The last two seemed to be in regard to the current review - each of those approximately 3"-4" in depth. Very "daunting" - to Mr. G. Q. Public! However, this letter is very "simple" - in its views and requests. 295

We are very much opposed to any expansion of the Sunshine Canyon Landfill. Our main concern has been, and continues to be, the close proximity to the water source at the Jensen Filtration plant (as well as area ground water). That is 296 297

not to say other concerns, such as odor, dust, debris, traffic and roadways, noise, ecology, and environmental/health related problems - are not also significantly troublesome. 298 301

Our feeling is that this is "on out of the ordinary/unique" situation - in respect to the "extremely close proximity to the water plant." As mentioned in the information letter, the Sunshine Landfill is a designated non-hazardous landfill. Certainly - that would be the ideal premise. However, it would surely be a certainty that hazardous waste would find its way into the landfill. Also, it's a certainty that the area is earthquake prone. It is our understanding that B.F.I. - the landfill operator, has been cited for numerous contamination violations, at other landfill operations. 302 303 304 305

Who is going to really listen to what "the people" have to say? Who is going to stand up for "the people"? Who is going to say "money doesn't talk"? We certainly hope we don't live 306

3/

So long as to see a situation of citywide water contamination. Given the other associated problems we probably won't! Please, please, please - someone - truly stand for the environment.

Sincerely,
Nancy & Phil Bogna

Gentlemen:

As Vice-President of the Santa Susana Mountains Park Association, I have been given the SAD task of replying to the Draft Subsequent EIR for the Sunshine Canyon Landfill (EIR Case # 91-0377-ZC/GPA). I use the word SAD quite intentionally. Despite the various mitigation measures associated with this project, the fact remains that a non-replaceable Oak Woodland enviroment will be almost completely destroyed by the Sunshine Canyon Landfil project. 307

When I first decided to comment on the pertinent EIR, my intention was to comment only on the Cultural Resources portion of the EIR. This because I was a crew member during one of the archaeological surveys of the canyon. Because of this survey participation, I had an opportunity to see the entire canyon for myself. I would like to say that the archaeological portions of the EIR is reasonably adequate....although I would have liked to have seen additional sub-soil testing of at least some of the areas where archaeological materials were located. However, I have decided to not comment at length on this aspect of the EIR..... 308

I do wish to say that, had the Sunshine Canyon area been personally examined by a large number of members of the local community, the project would have never been allowed to proceed. If a large number of members of the local community been allowed to see the area for themselves, I have no doubt that a considerable number of people would have tried to block the entrance to the canyon, to prevent work from proceeding. 309

In my opinion, and in the opinion(s) of the membership of the SSMPA, the destruction of the Sunshine Canyon ecosystem is a crime against our regional enviroment. 310 The destruction of 1000s of mature Oak trees in the beautiful canyon bottom, 311 and the displacement (and death) of countless animals IS NOT and CAN NOT be mitigated, even by the protection of the adjacent canyon, and by the creation of a phony replacement forest, on the slopes above the canyon bottom. 312

The membership of the SSMPA, including myself, are deeply saddened by the negative effects that this project is having and will have in the future. We all want your office to know that we will NEVER permit another land fill of this type to be established in the Santa Susana Mountains, either in Los Angeles or in Ventura County. 313

Please do not give us cause to turn our sadness into anger- by proposing or by planning another massive land fill of this type. Please do not continue to see our wonderful regional natural heritage as expendable.... 314

The destruction of the Sunshine Canyon ecosystem is an outrage....please do not repeat the process elsewhere. 315

Sincerely,

Albert Knight

Dear Hader Plafkin + L.A.C.P.D

I just heard about the Sunshine Canyon Landfill. There are many aspects of this landfill that disturb me:

1.) the health risks from such a huge dump being so close to a residential area (particulates, cancer, asthma, childhood illnesses, assorted infectious diseases); 316

2.) the history of Browning Ferris Industries in other parts of the nation concerning racketeering; 317

3.) the history of BFI in regards to uncorrected violations from the old city portion of the dump; 318

4.) the increased air pollution in the valley from the dump, especially because of its location in the wind tunnel of the Santa Suzanna Pass; 319

5.) the inevitable contamination of the water reservoir downwind and downhill from the dump site; 320

6.) the site not being earthquake unstable, and the resultant "liner" damage and leakage into the water table. 321

7.) the harmful gases that are generated from the decomposition. 322

8.) the county and city reneging on keeping the old site closed, and converted into a recreational center according to the original agreement from the 60's. 323

9.) the city's and county's rationale being driven purely by money, and the "politics" of it all, verses, what is right and protective of human beings. 324

10.) How we'll be able to explain, or not explain, all this devastation to our children and grandchildren. 325

... and perhaps you know more controversial issues. 326

Please oppose this landfill expansion. Please.

Sincerely,

Ed You

Attn.: Hadar Plafkin, City Planner

Ref. Case No. 97-0377-ZC/GPA, Sunshine Canyon Landfill

I have many concerns and questions regarding the proposed opening of the Sunshine Canyon Landfill. I understand that disposal of trash in a city the size of Los Angeles is a serious problem; however, quality of life for the citizens of Los Angeles is also of concern. 327

It seems the city/county is willing to sacrifice a neighborhood and perhaps the quality of the water supply of Los Angeles in the interest of trash disposal. Some concerns and questions follow. 328

1. The dump is located upwind of water treatment facilities for the City of Los Angeles and surrounding counties. The issues of blowing dust and ground water contamination exist. 329 The potential for earthquake damage to the dump liner and damage to the Balboa inlet tunnel with subsequent groundwater contamination is a concern. 330

2. This area experiences heavy winds. In addition to the drinking water reservoir, there are many homes in the area downwind from the dump. It was a problem in the early years of the dump. What will be done so it will not be a problem again with more dumping and higher volume dumping? Will the dump shut down on extremely windy days in an effort to protect the community? 331

3. What about the impact on the community and traffic on Balboa Blvd. with the addition of trucks hauling a potential of 14,000 tons of trash a day on an already busy street. 332 333 Will it become the dump for the entire region? 334 Has the contamination of the air due to diesel exhaust been addressed or will the trucks be running on clean fuel?

4. Will there be an independent health inspection process? 335

One basic question remains. What is being done to ensure that the dump is not a terrible mistake? And if it is a mistake, as many people believe, what can be done to close it down? 336

Re: Draft EIR File No. 91-0377-ZC/GPA
Site Location 14747 San Fernando Rd., Sylmar, Ca 91342

Dear Mr. Plafkin:

I represent the Newhall Hidden Valley Homeowners Association.

After review and consideration of the above referenced draft subsequent environment impact report the Board of Directors of the Newhall Hidden Valley Homeowners Association has resolved to oppose the development. 337

Specifically, increased traffic of heavy vehicles on already crowded roadways and proximity of the development to residential areas constitute a threat to the air quality, safety, and quality of life of the residents of Hidden Valley. 338

If you have any questions, please do not hesitate to contact me. Thank you.

Very truly yours,

JEFFREY H. HILL

Dept of Regional Planning
Environmental Review Section

Nov.3, 1997

Dear Hadar Plafkin,

We are writing in advance of submitting our comments on the draft EIR for Sunshine Canyon to seek a clarification. The letter that accompanied the EIR states that BFI is seeking a permit to receive 11,000 tpd at the Sunshine Canyon Landfill site. BFI already has permission to import 9,000 tpd in their Solid Waste Facilities Permit (i.e. 6,000-6,600 tpd of buried waste, plus the remainder up to 9000 tpd consisting of waste that the County calls "exempt.") This "exempt waste," of course, arrives by truck creating the same impacts associated with traffic and air quality as the buried waste. Few of these items will leave the site. 339

Is BFI then seeking approval to import an additional 2,000 tpd to reach 11,000 tpd, as your letter suggests or 5000-5,500 tpd making the inflow requested 14,000-14,500? 340

This is a very significant difference and we cannot evaluate the potential impacts of this project without it. Knowing the time constraints placed upon submitting our response, please clarify as soon as possible. 341

Thank You,

Mary Edwards

4.1 EARTH RESOURCES

FEIR Documentation, Page 4-3
According to the proponent: "The following list of references specific volumes, sections, and page numbers of the certified FIER and its incorporated technical documentation that provide background information and technical analyses relevant to the topic of earth resources. Development of the proposed project, including the additional +/-42 acres located in County jurisdiction, has been previously addressed within the context of this certified FEIR. Any new potential earth resources impacts associated with the proposed project and the relocation of ancillary facilities and environmental protection and control systems onto City lands will be addressed in the Draft SEIR." It goes on to cite numerous volumes, Sections, Appendixes, Topical Responses, and goes on to give a summary in Appendix C1. Why wasn't this material included? This material should have been include as a part of the SEIR since it is impossible for the public to determine the difference between old and "new potential impacts". Have the reviewing agencies been provided this documentation, if not have they reviewed the referenced material in order to determine whether or not there are any new potential impacts between County FIER and City SEIR? The public must be given more time to review this document. The proponent has maliciously denied the local homeowners/organizations copies of this SEIR, choosing instead to deliver them to such places a Westwood. It is also stated that several geologic assessments of the entire Sunshine Canyon area (owned by the project proponent) have been conducted including Robert Bean 1978; Geolabs 1981; The Earth Technology Corporation 1988; PRA Group 1982, 1989, 1991, and 1994. Why were these studies not included and where are they located? The review of the referenced data alone would occupy the entire time allotted to review the entire SEIR. How can the working public be expected to review this document and the referenced documents in the time allowed? Additionally, the referenced EIR does not reflect the actual proposals/mitigations implemented in the County to-date. There are changes in which BFI has sought County approval for modification due to cost, an inability to meet the goals as stated, new regulations, and new technology application. Why have these changes not been identified, the reasons, the approving agency and included? Many of the sections referenced did not address the public's requests for answers during the EIR process. Repeated attempts to have the proponent address the questions asked were ignored and lumped under a topical response that did not address the questions asked. Further , the proponent frequently sidestepped impacts to the residents by saying that they were only reviewing the County side and that impacts to the City would be addressed later. The entire portions of the documents referenced must be included in order for the public and the City agencies to properly assess the information provided.

342
343
344
345
346
347
348
349
350
351

ENVIRONMENTAL IMPACT, Page 4-4
In paragraph 3, it states that: "Excess material from grading activities would be stockpiled and stored within areas of the City/County Landfill footprint, as shown in Figure 4.1-1, throughout project development, and in paragraph 4 it states that: "It is anticipated that stockpiling would initially occur in the County portion of Sunshine Canyon, within the northern canyon area. This area is normally being used as a stockpile area for County Landfill operations." Given the anticipated closure of County operations in favor of the City expansion in 2 -3 years, and given the contours drawn over the northern canyon area, it appears that this canyon must be filled prior to the need for the stockpiled dirt in the City? If this is so where will this and the already stockpiled County dirt be moved to? Has this potential moving of stockpiled dirt for a second or third occasion been addressed in the impacts to air quality? The area shown on the City side and marked as "Anticipated Stock Pile Area" is on the western end of the berm in an area that is most exposed to the wind and in the closest proximity to the residents to the south. Given the fact that BFI has been unable to control dust in this area before (please refer to prior Zoning actions for testimony and pictures) and given the fact that they are unable to mitigate the air quality impacts they

352
353
354
355

should not be permitted to utilize this area for any dump related activities. It should also be noted that the existing landfill is closed and that final cover is required for this area.

356

Lithologic Description, Page 4-12
Figure 4.1-3 is said to represent the locations of monitoring wells and exploratory borings. Based on this map there are no monitoring wells located near the entrance of the landfill. Why not? Figure 4.1-4 is reported to depict the geologic formations. Apparently, this figure was intended to be viewed in color as the following items under the legend are indistinguishable from each other. Contact, Mappable Bed within mappable unit, and Fault. Please provide a color map and/or one with legend items sufficiently different to discern the various geologic features.

357
358

Soils, Page 4-19
The proponent states that: "Surficial soils are important for varying reasons. Soil characteristics have an impact of nearly all aspects of design and construction of the proposed project, ancillary facilities, and areas, in addition to the development of an erosion control and revegetation plan.." Why doesn't the proponent note that this can also have an effect on air quality? Given the depth of soils indicated in paragraph 2, how can the proponent compare and justify the use of TSP from Transit Mixed Concrete's proposed site in Soledad Canyon Road located 10 miles from Sunshine?

359
360

Onsite Landslides, Page 4-20
It states that landslides are identified on Figure 4.1-4. It goes to state that in paragraph 3 that: "Another landslide is located southeast of the existing inactive landfill, south of the landfill entrance and adjacent to San Fernando Road." The section mentioned is not discernible on the figure. Why? The proponent states that this landslide is not expected to impact proposed landfill development due to its distance from the footprint of the waste fill and drainage systems. Does this landslide pose any danger to any ancillary facilities? Could it possibly affect the County drainage system?

361
362

ENVIRONMENTAL IMPACT, Page 4-22
In paragraphs 3, 4, and 5 the proponent dismisses potential landslides either seismically or as a result of future operations. The proponent is not being candid. Why is it not discussed that the largest landslide during the 1971 San Fernando earthquake was on the northern edge of Caltrans land adjacent to the existing closed City landfill in the area that will undergo extensive grading? What about the collapsed ridge just south of the City/County line? What about the collapsed southeastern end of the berm during the 1994 Northridge earthquake? What about the extensive mud slides at the entrance that washed over San Fernando Road during extremely wet period in circa 1996? Why is there no discussion of the problems with sliding when a watertank and the City incinerator were being constructed on the southwestern end of the berm area? Why aren't these things documented and placed on a map? Given that at various Zoning hearings the proponent has always claimed that land movement problems were unanticipated and that varied and sometimes extensive earthmoving activities were required to correct. If this is true how can the proponent just summarily dismiss landslides?

363
364
365
366
367
368
369

Figure 4.1-5, Page 4-26
In describing the Santa Susana Fault on page 4-31 the proponent states that the shortest distance between the ground surface at the project site and the fault itself is 3.1 miles. How is this possible since the entrance to the landfill and the I-5 where the fault crosses (Balboa Boulevarrd) is less than 1.0 mile?

370

CUMULATIVE IMPACTS, Page 4-23
Again the proponent does not even attempt to address the problems. As stated above the proponent is not candid and seeks only to promote the project.

371

ENVIRONMENTAL IMPACT, Page 4-32

Regulatory Background

A number of paragraphs discuss State and Federal regulations that address seismic design criteria. Appendix C-15 contains a Static and Seismic Stability Assessment, Proposed Phase II Construction, Sunshine Canyon Landfill Extension, dated November 1996. Exhibit (WH-6), letter from Leslie F. Harder, Jr., Chief, Division of Engineering, Department of Water Resources dated July 21, 1997 to Mr. Rodney Nelson, Chief of Landfills Unit, California Regional Water Quality Control Board should be included as it points out deficiencies in this report. Why hasn't the proponent included this material? 372

CUMULATIVE IMPACT, Page 4-44

Again the proponent does not even attempt to address the problems. As stated above the proponent is not candid and seeks only to promote the project. See response to Enrivonmental Impact, 4-22. 373

General Comments and Observations, 4.1 Earth Resouces, Pages 4-3 thru 4-44

Given sections 4.1.3, Geologic Hazards - Subsidence and 4.1.4, Geologic Hazards - Seismicity, the following Exhibit (WH-8), U.S.Geological Survey Open-File Report 96-517 should also be included. Why wasn't this kind of information included? Does the subsidence and/or elevation as described in this report affect the landfill and the area immediately surrounding it? Is there a possibility groundwater could be altered, drainage problems develop or leachate collection be affected in any way? 374 375 376

Wayde Hunter

North Valley Coalition
Response to
SIER 91-0377-ZC/GPA
November, 1997

4.2 Air Quality

FEIR Documentation, Page 4-45

According to the proponent: "The following list references specific volumes, sections, and page numbers of the certified FEIR and its incorporated technical documentation that provide background information and technical analyses relevant to the topical issue of air quality. Development of the proposed project, including the additional +/-42 acres located in County jurisdiction, has been previously addressed within the context of this certified FEIR. Any new potential air quality impacts associated with the proposed project and the relocation of ancillary facilities and environmental protection and control systems onto City lands will be addressed in the Draft SEIR." 377

It goes on to cite numerous volumes, Sections, Appendixes, Topical Responses, and goes on to give a summary in Appendix C1. Why was this material not included? This material should have been included as a part of the SEIR since it is impossible for the public to determine the difference between old and "new potential impacts". Have the reviewing agencies been provided this documentation, if not have they reviewed the referenced material in order to determine whether or not there are any new potential impacts between County FEIR and City SIER? The public must be given more time to review this document. The proponent has maliciously denied the local homeowners organizations/associations copies of this SEIR, choosing instead to deliver them to such places as Westwood. Additionally, there other related documents incorporated by reference that are supposedly available for review:- Report of Waste Discharge Proposed Sunshine Canyon Extension Site, Report of Disposal Site Information Volumes I, II, and Addendum 1, Final Closure Plan for Sunshine Canyon, Addendum to the Final Closure and Post Closure Maintenance Plans for Sunshine Canyon City Landfill in such diverse sites as Monterey Park and Los Angeles. How can the working public be expected to research the documents referenced which are only located in libraries or remote sites over 25 miles away? Saturday is the only real chance for the working public to review but how are so many people suppose to share the single copy of the FIER located at each library given the time frame allotted? Are the Department of Health Services or the Planning Department for the City of Los Angeles even open on a Saturday? The review of this referenced data alone would occupy the entire time allotted to review the entire SEIR. Additionally, the referenced EIR does not reflect the actual proposals/mitigations implemented in the County to-date. There are changes in which BFI has sought County approval for modification due to cost, an inability to meet the goals as stated, new regulations, and new technology application. Why have these changes not been identified, the reasons, and the approving agency and included? Many of the sections referenced did not address the public's request for answers during the EIR process. Repeated attempts to have the proponent address residents concerns were ignored and lumped under a topical response that did not address the questions asked. Further, the proponent frequently sidestepped impacts to the residents by saying that the they were only reviewing the County side and that impacts to the City would be addressed later. The entire portions of the documents referenced must be included in order for the public and the City agencies to properly assess the information provided.

378 379 380 381 382 383 384 385 386 387 388 389

Environmental Setting, Page 4-45

4.2.1 Existing Conditions & 4.2.2 California's SCAB Regional Climatic Characteristics

Under the Existing Conditions section the reader is lead to believe that site-specific information is about to follow, however, the information presented is only a broad description of the South Coast Air Basin. The next section 4.2.2, California's SCAB Regional Climatic Characteristics under the headings of Climate, Precipitation, and Humidity – the reader is again given only generalities, not site-specific information. Under the heading Temperature, on page 4-46, the reader is informed that a SCAQMD monitoring station located at 24875 San Fernando Road in Newhall may generally be consider to be representative of the project area. What other monitoring stations were considered and why were they considered not representative? When the topic of Wind on page 4-47 is discussed, site-specific information is now included in the form of figure 4.4.2, Windrose for the Sunshine Canyon Landfill. The proponent again returns to SCAB generalities under the headings of Cloudiness, and Inversions. What are the site-specific characteristics of this project under the headings presented? What are the impacts of these weather conditions to the proposed project and to the public health?

390 391 392 393 394 395 396

While the topic of Wind on page 4-47 deals in generalities it discusses wind on-site measurements as having an overall averaged wind speed of 9.9 mph with a maximum 1-hour measurement of 45 mph. It goes on to state that it does not preclude the presence of very high wind speeds. Why has this database of readings been included at this point? What high wind speeds have been recorded at the landfill both City and County? The Windrose and anemometer readings included in Appendix B8 are for Site 1. There are at least two other sites. Where is Site 1 located? Why has the wind speed data that has already been gathered on-site during the operation of the old City landfill and the currently operating County landfill not been provided? During past operations on the City side of the landfill, the South Coast Air Quality Management District inspectors observed the anemometer located there to be holding steady at 100 mph with gusts estimated at 125 mph. As recently as 10/13/97 the Daily Activity Log Sheet for the County landfill and signed by Ken Murray, County Inspector, records winds of 50 – 60 miles per hour. Santa Ana conditions are said to average 5 –10 occurrences per year. What parameters establish them as Santa Ana's? What speeds and durations were recorded at both city/county landfills?

397 398 399 400 401 402 403

4.2.3 Criteria Air Pollutants, Page 4-51

The definitions of Carbon Monoxide, Reactive Organic Gases, et cetera are taken from what source?

404

4.2.4 Ambient Air Quality Standards and Annual Statistics, Page 4-53

The proponent merely seeks to advance his own project and does not attempt to provide information for the public or the agencies to evaluated the impacts. When information is presented which does not advance or support the proponents position explanations are included which minimize the impacts, for example:

405

Under the heading Existing Air Quality, on page 4-53 after referencing the SCAQMD monitoring station located at 24875 San Fernando Road in Newhall and Table 4.4-2 the proponent explains in the last sentence that the larger particles are filtered out by the respiratory system and pose more of a nuisance than a health threat. What studies is this assumption based on? The proponent goes on talk about (PM_{10}) but other than explaining possible sources does not address the health impacts as they did for the larger particles. Why? On page 4-55 the proponent in the last sentence before 4.2.5 states that the data in Table 4.2-2 suggests that the air quality problems in the study area are mainly due to the transport of pollutants into the area from upwind sources. What was this determination based on and who made it? Does the SCAQMD agree with this assessment? If the project area is "(v)ery sensitive to additional O_3 precursor and particulate

406 407 408 409 410

pollutant. . ." as the proponent suggests and given the fact that landfills are the largest stationary source of pollutants, what impact will this project have on the Santa Clarita Valley since winds blow both directions? Does the SCAQMD have to consider those impacts and if not why? What are the impacts to residents of the San Fernando Valley in the area immediately surrounding the landfill given that the Federal standards have been revised and that additional studies such as those exhibits attached are now available? The attached Consumer Report excerpt page 36, 37, & 38 and dated August 1997 (Exhibit WH-1) states that: "Scientists have detected a sizable and reliable connection between dirty air and health problems in dozens of communities large and small, old and new, in every type of climate, throughout North America." It further goes on to state that : "So consistent is the association that epidemiologists can even estimate the annual U.S. toll from air pollution-about 50,000 deaths from heart disease, asthma, stroke, bronchitis, and the like."

411
412
413

On page 37, column 1 of the article, it states that: "Two significant contributors to these effects are ozone and particulate matter (emphasis added). Under ozone it states that many studies have found harmful consequences. "Children at a Connecticut asthma camp were 40 percent more likely to have an acute asthma attack on high ozone summer days than on average days." "The first results of an ongoing 10-year study of southern California schoolchildren has found a direct correlation between school absences and lifetime exposure to ozone." "Studies in major U.S. cities show that daily mortality rates increase along with ozone, even if the ozone is below current legal limits".

Under Particulates in column 2 the article says that: "A few weeks ago, researchers reported that infant mortality in the most polluted communities is 25 percent higher than in the cleanest ones. "A study of 13,000 children in 24 North American communities found that youngsters in the community with the worst fine-particle pollution had 65 percent more bronchitis than those in the cleanest community." "The most striking evidenced comes for the so-called Six City study, in which researchers from Harvard and Brigham Young universities followed more than 8000 adults for an average of 15 years, comparing their health to local fine-particle counts." The results revealed that the city with the most small-article pollution, had 25 percent higher mortality rate (emphasis added). than residents of the cleanest city. The study was repeated using 500,000 adults in 151 communities and similar results were obtained.

414

Another article that bolsters this information is a story in the Daily News, dated Thursday, November 20, 1997 in which a study paid for by the AQMD tied daily air pollution measurements to patient admissions at Kaiser Permanente hospitals including Woodland Hills and Panorama City (Exhibit WH-2). "This is the first study of its kind conducted in the (Los Angeles) Basin and shows that the region's air pollution continues to be a leading public health concern," said Shankar Prasad, health effects officer for the South Coast Air Quality Management District. The Kaiser study matched ozone levels and particulate emissions throughout 1995 with Kaiser records covering 1.6 million patients. For every 10-microgram increase in the concentration of particulates, hospital admissions rose an average of 7 percent for chronic respiratory illnesses, 3 percent for cardiovascular disease and 3.5 percent for acute respiratory illnesses. Ozone had a similarly hazardous effect. During the study, when ozone concentrations in the air rose by 10 parts per billion, an average of 2.7 percent more people with chronic respiratory problems, 5.7 percent more cardiovascular disease suffers and 1.5 percent more people with acute respiratory disease check themselves into the hospital. Additional excerpts of articles dealing with the harmful effects of emissions and PM_{10} are also included (Los Angeles Times, Sunday, November 23, 1997 – Exhibit WH-3), Coalition for Clean Air, Spring 1997 – Exhibit WH-4), The Amicus Journal, Summer 1997 – Exhibit WH-5).

Residents have called on numerous occasions in the past for health studies to be performed. It has been stated by residents at past Zoning hearings and in response to the EIR that cancer clusters exist in the Granada Hills neighborhood nearest the landfill. An informal health survey was provided that showed that residents in this area suffered twice the national average of upper

415

↓

respiratory distress. BFI denied the voracity of this information and later failed to provide the health study as ordered by the Zoning Board and Board of Zoning Appeals. BFI has refused to comply with this and other conditions imposed on them by claiming that the City did not have the right to make them do anything since the Variance had expired. See Exhibit (WH-7), Second Draft, Hearings and Conditions, September 1991. How can a proponent with these past failures to comply with City Zoning be trusted or granted another approval when the health and welfare of residents are at risk? How can the City even consider this project without adequate health studies?

416
417
418

Fugitive Dust Emissions, Page 4-62

In the second sentence of this section it is states that AP-42, Compilation of Air Pollutant Emission Factors (USEPA, 1985) is used to derive a factor of 110 pounds of total suspended particulate matter (TSP) per day, per acre graded. It goes on to state that this value is based on a medium level of activity, silt content of about 30 percent, and a semiarid climate. The following statement is not understood. "Test data used to derive the specified value are not sufficient to derive the specific dependence of dust emissions on correction parameters and for the purposes of this analysis, none have been applied". Is the proponent saying that the proposed expansion site does not meet these criteria? Please explain? What test data is being referred to and why was it not included? In the third sentence it refers to tests conducted by Transit Mixed Concrete at their proposed site in Soledad Canyon Road located 10 miles away producing a TSP of only 28.6 percent as opposed to the 45 percent in AP-42. In sentence four, the proponent switches to a new calculation for PM_{10} based on this information. Why wasn't documentation included to support why this data more accurately reflects conditions at the landfill site? Does the SCAMD agree with this assessment? How does the overall makeup of the soil and geology compare to each other? Based on this misapplication of data, Table 4.2-6 on page 4-63 is understated by at least 17 percent. The preparer states that "Construction work at the proposed landfill footprint would disturb a relatively small area (estimated not to exceed 40 acres at any given time). In accordance with information provided by the project proponent, actual excavation operations would be further restricted to an even smaller area not expected to exceed about 10 acres per day of the 40 acre footprint." Forty acres or even 10 acres is not a "relatively small area" when located in the wind tunnel that is the Newhall-Saugus Pass. Given the terrain and the existing weather conditions it is not possible to mitigate the dust. Past zoning actions and the EIR for the County expansion contain documentation and pictures of dust produced in the City landfill (now closed) of dust being visible for 10.4 miles away, of dust blowing from berms and hillsides, of water from watering trucks being blown into the air without ever touching the ground. What guarantees are in place to insure that all surfaces once disturbed during construction and to the completion of construction are properly sealed and/or watered given the steep nature of the terrain and the ferocious winds? Please explain how the proponent can mitigate dust when they have been unable to revegetate the closed City landfill or even the cut slopes on the County landfill? Please explain how water trucks will gain access to cut slopes? In the last sentence on this page the preparer accepts that the USEPA, AP-42 estimates that regular watering may (emphasis added) reduce fugitive dust emissions by as much as 50 percent. Here it suits their purposes to accept a rate that as stated before will exceed their ability to attain. What permits the preparer to accept or reject parts of such documents as the AP-42 at will to minimize or promote this project? Do the reviewing agencies concur with this approach? The PM_{10} emissions given on page 4-63, Table 4.2-6 is totally understated based on BFI's selection/manipulation of data parameters.

430
431
432

Table 4.2-5, Construction Emissions for Initial Site Preparation is not correct. The proponent fails to state the cumulative impacts because the landfill will continue to take trash even while the City side is being constructed. Trash will also be accepted on the City side once the most basic City infrastructure/construction has been attained. How will construction proceed and how long will construction last? Why hasn't the proponent taken into account the cumulative impacts?

433
434
435

4.2.8 Air Quality Operational Phase (Long-Term), Page 4-64

This section states that: "At full operation, the proposed project (combined landfill within both jurisdictions) will receive an anticipated average solid waste intake of approximately 11,000 tons per day (tpd)". On Tuesday, November 18, 1997 at a Proposed General Plan Amendment/Zone Change Meeting held in Granada Hills, the proponents when asked if the 11,000 tpd was correct indicated that it was not and that the tonnage would be much higher than the 11,000 stated in the SEIR. The SIER does not take into account that the County has a permitted inflow rate and that it will continue to operate as the new City/County landfill is constructed: Further, the green waste from both sides has been excluded. Given that the tonnage will be much higher, all subsequent Tables 4.2-7 Heavy Equipment Emissions for Site Operations, Table 4.2-8 Operation Gaseous Emissions, Table 4.2-9 Permitted Daily Emissions from Flaring Activities, 4.2-10 Estimated Emissions for Truck Travel over Unpaved Surfaces, Table 4.2-11 Estimated Fugitive Dust PM_{10} Emissions for Site Operations, et cetera do not accurately reflect the air impacts.

436

437

438

Combustion of Landfill Gas Emissions, Page 4-68

The proponent presents a confusing discussion of the status of flaring stations in the City and County and then goes on the state that the permitted emissions for combustion are presented in Table 4.2-9. It is unclear what this table really represents. Is it two flares (one existing City flare and the one County flare that has been built) or is it three flares (one existing City flare and the two permitted County flares)? The note section under the table on 4-69 makes things no clearer and no calculations are included to show how the proponent arrives at the final lb./day. As stated before this table cannot be correct. On Tuesday, November 18, 1997 at a Proposed General Plan Amendment/Zone Change Meeting held in Granada Hills, the proponents when asked if the 11,000 tpd was correct indicated that it was not and that the tonnage would be much higher than the 11,000 stated in the SEIR.

439

440

Fugitive Dust, Page 4-70

Under the title Active Working Face Area, Page 4-70. Where is the value of 31.5 pounds of PM10 per acre per day derived from and what is the basis for reducing it to approximately 19 pounds during daily cover and compaction operations?

441

Under the title Landfill Area Excavation, Page 4-70. Where is the value of 31.5 pounds of PM10 per acre per day derived from and what is the basis for reducing it to approximately 38 pounds during landfill excavation?

442

Under the title Stockpile Erosion, Page 4-71. It is stated "By adjusting this value to reflect the reduced onsite PM_{10} content, approximately 35 pounds of PM_{10} emissions would be released daily". What was this value? What data supports this reduction? Does the SCAMD agree with this reduction?

443

Under the title Vehicular Travel on Paved Surfaces, Page4-71. The emissions are based on 1110 trucks. The emissions cannot be correct. As stated before On Tuesday, November 18, 1997 at a Proposed General Plan Amendment/Zone Change Meeting held in Granada Hills, the proponents when asked if the 11,000 tpd was correct indicated that it was not and that the tonnage would be much higher than the 11,000 stated in the SEIR.

444

Under the title Truck Travel on Unpaved Surfaces, Page 4-71. The emissions cannot be correct. On Tuesday, November 18, 1997 at a Proposed General Plan Amendment/Zone Change Meeting held in Granada Hills, the proponents when asked if the 11,000 tpd was correct indicated that it was not and that the tonnage would be much higher than the 11,000 stated in the SEIR.

445

4.2-9 Health Risk Analysis, Page 4-74

On page it states that the USEPA SCREEN2 dispersion model was utilized to determine the maximum pollutant concentration at downwind receptors locations. On page 4-76 it also states that "It should be noted that the SCREEN2 model is not designed for a complex terrain such as Sunshine Canyon". This is followed by a statement that the model will over predict rather than under predict the health risks. We believe that this is not the case. The assumption that the terrain were flat and that zero plume rising doesn't take into account that there are severe downdrafts, vortexes, and eddies which may cause a plume to be depressed below its exit point. Are there no other models more appropriate? Is this the model recommended by the SCAQMD?

446

447

The risk analysis modeling is based on in-flare exhaust concentrations derived from the existing landfill flare station and augmented to a combustion rate of 4,400 cubic feet per minute. Why doesn't the modeling include the cumulative rates from both the City and the County both existing (2 flares) and future (5 flares)? Why aren't the cumulative impacts of all the landfilling, construction and combined with the ambient air also considered? Does this model, and the Table 4.2-13 on page 4-76 in any way represent the cumulative toxics and the cumulative cancer risks that the public will be exposed to by all landfilling activities or just LFG flaring? If not, how does the proponent or the AQMD justify presenting it as a true Health Risk Assessment?

448

449

450

451

Air Quality Management Plan, Page 4-77

The determination of consistency with the AQMP given on page 4-78 represents a gross misrepresentation of the facts by the proponent. To begin with, the proponent makes the statement that: "In accordance with that document, a project conforms with the AQMP if the following consistency requirements are met". The reader expects to see a list of the requirements. The proponent now mixes requirements with self-serving explanations in 3 out of 4 bullets. It is apparent that the proponent does not meet the established guidelines.

452

The first bullet in part states that: "(t)he County portion of the project site is located within a job-poor region and will positively contribute to job opportunities available within this region". Since the County portion of landfill is only 40 acres and will be the first section to close, and since workers will be hired regardless of where they may live, this statement is plainly not supported by fact.

453

In the second bullet the proponent would have you believe that the level of service on traffic routes will not be degraded below acceptable levels. The proponent has understated the total tonnage to be received (City & County in operation at same time plus excluded recycling) and therefore the vehicle trips. The proponent has also not provided current traffic data, has made erroneous assumptions as to the traffic composition, and has not forecast impacts beyond 1998.

454

In the third bullet the proponent reverts to a statement of requirements as addressed in SCAG's Guideline for Implementation of 1989 AQMP Conformity Procedures but does not make any claims that this has been satisfied.

455

In the fourth bullet after acknowledging that the impact analysis demonstrates that significant levels of air pollutants will be generated, launches into the most egregious, self-serving, totally asinine justification for imperiling the health and welfare for the residents in the area surrounding the landfill by claiming that "(t)he exhaust and particulate emissions associated with project implementation would be associated with another landfill project".

456

Page 4-79 further illustrates our point about the confusing mix of fact, data, and the proponent's attempts to minimize any negative information. The continuation of the previous subject addresses the 1997 Draft AQMP but does so with bullets that merely highlight information and do not contain any intrusive and self-serving comments.

457

Growth Management Chapter, Page 4-79

On page 4-81 it states that "the project site (within the County) is within the Santa Clarita subarea which has a jobs/housing ratio of 1.18 for the year 2010 making this region jobs poor." It goes on to state that : "Therefore implementation of the project would therefore serve to improve the jobs/housing balance in this subarea and subregion by providing additional job opportunities". This statement is plainly not true for a number of reasons. Workers will be hired regardless of where they may live. Additionally, this project involves only 35 jobs and only a fraction of them would be employed on the County portion of landfill (42 acres) and likely the first section to close. 458 459

When speaking of the general plan amendment required for the project the proponent noted that: "residential use onsite would not be a feasible option at this location". While this is true it should be noted that SCAG encourages existing or proposed local jurisdictions programs which create opportunities for residents to walk and bike and that the closed City landfill and its environs were to be offered to the Department of Parks & Recreation, City of Los Angeles upon closure. 460

The proponent goes on to state that: "The development of a landfill within this project site would significantly reduce infrastructure cost...". If relevant policies of SCAG are used which encourage patterns of land use which reduce costs in infrastructure construction and make better use of facilities, why isn't it noted that this is conflict with SCAGs policy to encourage existing or proposed local jurisdictions programs which create opportunities for residents to walk and bike. To what advantage is this to the general public and why would this be a reason to approve the project? 461

The proponent also says that "If project development does not occur, transportation or hauling costs to other landfill facilities located either in-County or out-of-County would increase due to greater travel distances". What data or assumptions is this information based on? 462 463

Does the SCAQMD agree with this assessment? The proponent also states that: the development of the proposed project would minimize many significant environmental impacts such as biological resources, development of new infrastructure, and air quality emission impacts associated with new site development, or the exportation of wastes to other landfills. Where is the data that supports these contentions? 464

Does the proponent consider that there may be offsetting factors given that other landfills may in fact reduce travel due to their proximity to the anticipate wastestream or that they may be less environmentally harmful than the project proposed? 465

City of Los Angeles Air Quality Element, Page 4-82

In Goal 1 the proponent states that the project supports consistency with the AQMP and sustenance of Citywide economic growth to obtain good air quality. How can this be when the landfill which is the largest stationary source of emissions is being expanded in an area with already poor quality air? 466 467

As requested before, where is the data that supports these contentions? Does the proponent consider that there may be offsetting factors given that other landfills may in fact reduce travel due to their proximity to the anticipate wastestream or that they may be less environmentally harmful than the project proposed? 468

In Goal 2 how does the proponent justify the statement "and thereby ensure attainment of this goal when fact, a). rideshare programs are not mandatory, b). that the AQMD is permitting monies to be paid rather than enforcing/encouraging ridesharing, and c). that given only 87 employees that they live in close enough proximity to each other to form even one carpool, let alone enough to have any impact on air quality? 469 470 471

In Goal 3 it is stated that transfer trucks that haul partial loads will be penalized, thereby encouraging full loads and reduced truck movement. What data supports this contention? Has BFI in the past enforced penalties and if so were partial loads reduced, what monies were collected and who was the beneficiary? 472 473

In Goal 4 it states that the project should minimize the impacts of land use development on air quality. A CEQA analysis and stand-alone health risk assessment is offered up. As stated by this respondent and others, these studies and others do not accurately reflect the impacts due to the 474

way in which parameters were manipulated, the understated inflow, the exclusion of green waste and wood waste recycling, and due to the fact that the studies do not represent cumulative impacts.

In Goal 5 it states that the project would include development of a green waste and wood waste recycling and public drop-off area to support recycling efforts in order to improve energy efficiency primarily at City facilities. How many tons per day are involved? Precisely how does this equate to energy efficiency primarily at City facilities? 475 476

Cumulative Impact, Page 4-83

In paragraph two of this section table 4.2.8 Air Quality Operational Phase (Long-Term), Page 4-64 is referenced. As stated before, on Tuesday, November 18, 1997 at a Proposed General Plan Amendment/Zone Change Meeting held in Granada Hills, the proponents when asked if the 11,000 tpd was correct indicated that it was not and that the tonnage would be much higher than the 11,000 stated in the SEIR. The SEIR does not take into account that the County has a permitted inflow rate and that it will continue to operate as the new City/County landfill is constructed. Further, the green waste from both sides has been excluded. Given that the tonnage will be much higher, all subsequent Tables 4.2-7 Heavy Equipment Emissions for Site Operations, Table 4.2-8 Operation Gaseous Emissions, Table 4.2-9 Permitted Daily Emissions from Flaring Activities, 4.2-10 Estimated Emissions for Truck Travel over Unpaved Surfaces, Table 4.2-11 Estimated Fugitive Dust PM_{10} Emissions for Site Operations, et cetera do not accurately reflect the air impacts. 477 478 479 480

City Mitigation Measures, Page 4-84

Under the title Exhaust Emission the proponent lists a series of bullets claiming that they will variously tune equipment, use catalytic converters, retard diesel engine injection, use high-pressure fuel injectors, use low-emission fuel, not leave equipment idling for long periods, and will curtail construction during smog alerts. As previously asked who will monitor these mitigations to ensure that they are implemented? Have these same mitigations not already been implemented for all on-site equipment because they would have been required mitigations in the County? 481 482

Table 4.2.14, Construction Emissions, Control Measure Reduction Efficiency, and Residual Emissions on page 4-85 is not correct. As stated before, on Tuesday, November 18, 1997 at a Proposed General Plan Amendment/Zone Change Meeting held in Granada Hills, the proponents when asked if the 11,000 tpd was correct indicated that it was not and that the tonnage would be much higher than the 11,000 stated in the SEIR. The SEIR does not take into account that the County has a permitted inflow rate and that it will continue to operate as the new City/County landfill is constructed. Further, the green waste from both sides has been excluded. Also see our response to Fugitive Dust Emissions, Page 4-62 section. 483 484 485

CITY MITIGATION MEASURES

4.2.11 Construction, Page 4-84

Under the title Exhaust Emissions the proponent states in a series of bullets that if these items are implemented it will reduce the emissions to the maximum extent possible. It is not clear whether or not this equipment will come from onsite or will be brought in especially for the construction. 486

What agency will check to insure that these mitigations are implemented? Given that the County expansion was already materially detrimental to the residents and that it was approved under overriding considerations shouldn't these pieces of equipment already be operated in such a manner? If not why? 487 488

Fugitive Dust, Page 4-86

The statement "Dust from construction activities, including physical site disturbance, material deliveries, employee commuting, and potential wind erosion during high wind episodes, may create a visual and soiling nuisance beyond the property line" should be revised to "will create". 489

It goes on to state that "because dust impacts are expected to be significant during the construction phase, standard mitigation measures (by project design) will be implemented... as required by SCAMD Rules 402 (Nuisance) and 403 (Fugitive Dust). What are rules 402 and 403 and why were they not included? 490

Are the mitigations that follow this statement "standard" or are they by "project design"? 491

Rule 403 used to preclude any enforcement if the winds were over 25 mph and the operator was making a reasonable attempt to control. Even if 403 has been revised how will this mitigate dust? 492

Under the mitigations measures that follow, the daily watering and soil stabilization, the graded areas shall be watered, the disturbed areas shall be revegetated with an interim groundcover as proposed is not attainable as previously outlined in our response to Fugitive Dust Emissions, Page 4-62 in which the preparer states that "Construction work at the proposed landfill footprint would disturb a relatively small area (estimated not to exceed 40 acres at any given time). In accordance with information provided by the project proponent, actual excavation operations would be further restricted to an even smaller area not expected to exceed about 10 acres per day of the 40 acre footprint." Forty acres or even 10 acres is not a "relatively small area" when located in the wind tunnel that is the Newhall-Saugus Pass. Given the terrain and the existing weather conditions it is not possible to mitigate the dust. 493

Past zoning actions and the EIR for the County expansion contain documentation and pictures of dust produced in the City landfill (now closed) of dust being visible for 10.4 miles away, of dust blowing from berms and hillsides, of water from watering trucks being blown into the air without ever touching the ground. What guarantees are in place to insure that all surfaces once disturbed during construction and to the completion of construction are properly sealed and/or watered given the steep nature of the terrain and the ferocious winds? 494

Please explain how the proponent can mitigate dust when they have been unable to revegetate the closed City landfill or even the cut slopes on the County landfill? 495

Please explain how water trucks will gain access to cut slopes? 496

In the next mitigation it states that the wind speed shall be continually monitored using onsite anemometers and excavation shall be halted when the 15-minute average wind speed exceeds 15 mph or when instantaneous wind speed exceeds 25 mph. The proponent fails to provide any details. 497

Since there are 3 anemometers onsite will the data be taken from all three sites and averaged? 498

If not from all three sites, which site will have precedence? 499

How will all workers be notified to cease operations and how long will this take? 500

Given the fact that winds spring up very quickly how does the proponent prevent dust from going offsite as the exposed areas can go up to 5 days without sealant, steep terrain will have no water, interim revegetation will not have had a chance to grow, therefore how can the dust be abated in a reasonable short period?

Fugitive Dust, Page 4-88

The applicant admits that: "past operations have shown that the higher-elevation upper plateau an southern berm areas of the existing inactive landfill have experienced greater wind-generated fugitive dust occurrences than the lower elevations within the canyon", and "the lack of revegetation on the active face of the landfill surface has exacerbated difficulties inadequately controlling fugitive dust emissions during periods of high wind conditions". The proponent claims success in other portions of the site. Specifically, precisely what areas are considered to be successful? 501

Do the responsible agencies agree with this assessment? 502

Has final cover been applied and has the required revegetation been accomplished? If not why? 503

The proponent's project will occupy precisely the same geographic location, will experience the same winds, and has admitted difficulties in controlling dust emissions. Nothing in the mitigations proffered in this SEIR can prevent dust from blowing off-site. 504

Table 4.2-15, Operational Emissions, Control Measure Reduction Efficiency, and Residual Emissions on page 4-89 is not correct. As stated before, on Tuesday, November 18, 1997 at a Proposed General Plan Amendment/Zone Change Meeting held in Granada Hills, the proponents when asked if the 11,000 tpd was correct indicated that it was not and that the tonnage would be much higher than the 11,000 stated in the SEIR. 505

The SEIR does not take into account that the County has a permitted inflow rate and that it will continue to operate as the new City/County landfill is constructed. Further, the green waste from both sides has been excluded. Also see our response to Fugitive Dust Emissions, Page 4-62 section. 506

Table 4.2-16, Operational Fugitive Dust PM10 Emissions, Control Measure Reduction Efficiency, and Residual Emissions on page 4-90 is not correct. As stated before, on Tuesday, November 18, 1997 at a Proposed General Plan Amendment/Zone Change Meeting held in Granada Hills, the proponents when asked if the 11,000 tpd was correct indicated that it was not and that the tonnage would be much higher than the 11,000 stated in the SEIR. 507

The SEIR does not take into account that the County has a permitted inflow rate and that it will continue to operate as the new City/County landfill is constructed. Further, the green waste from both sides has been excluded. Also see our response to Fugitive Dust Emissions, Page 4-62 section. 508

General Observations and Comments

The SEIR as presented represents nothing more than a self-serving document perpetuated by the proponent in an effort to gain approval for an environmentally unsafe project. The document is a contorted mix of referenced data, which is not included, and of tables based on assumptions without supporting data and which fail to present the cumulative impacts of the project and as such is a violation of California Environmental Quality Act (CEQA). 509

The SEIR represents an incremental approval of entire original project as proposed (215 million ton City/County Landfill) and as such is a violation of the California Environmental Quality Act (CEQA). 510

This document is replete with mitigations that are suggested "as possible" but in fact may not ever be done. Only mitigations that are to be implemented should be permitted to remain. 511

Recycling will be located on the southern berm in the area that is the nearest to the residents. 512
There is no discussion of the emissions, noise, and odors from this type of operation. 513
No discussion of truck trips generated. Also there is no discussion of viewsheds to the residential area to the south of the landfill. 514

The landfills past violations and actions relating to City agencies must be taken into account when reviewing this SEIR. BFI, the proponent has refused to comply with their original Variance and the additional Conditions that were applied by various Zoning Administrators, Boards of Zoning Appeals, the Planned Land Use Committee, and the City Council. 515

Changes to the conditions of final approval at the current County expansion must be taken into account. The proponent makes many proposals for compliance or mitigation in the EIR in order to gain approval but then has subsequently sought changes. These changes were not identified in the SEIR. 516

There is no discussion on the effects on the property values of residents. 517

There is no discussion on the quality of life. 518

A one day traffic study was conducted with the aid of Councilman Bernson's office in late November 1997. The results do not support or validate the proponents outdated studies. 519

The composition of the landfill both City and County would not be the same if the use of tarps and alternate cover continues. The lack of dirt can result in an entirely different structure which will possibly negate the seismic loading data, leachate production, stability, et cetera. 520

The drainage from the County landfill and the upper reaches of Sunshine Canyon are shown to be dependent on concrete culverts located on top of the already closed City landfill both southern and northern portions. The raising of a hill of trash which effectively blocks the drainage of the upper canyon and then routes it over existing trash is a recipe for disaster. Blockages or breaks may occur may occur during flood events and/or in conjunction with seismic activity which may cause the water to overflow or undercut the channels. These kind of scenarios will result in trash being washed out and that can either contaminate the waters flowing from the mouth of the canyon and/or undermine the integrity of the landfill. 521

Exhibit (WH-1)

AIR QUALITY • SPECIAL REPORT

Clearing the air

Is our air clean enough?

It was what scientists call a "natural experiment," a serendipitous way to study, in this case, whether people would be healthier if the air were cleaner. An environmental economist at Brigham Young University spotted the research opportunity: A labor dispute had shut down the steel mill near Provo, Utah, for 13 months, removing the major source of air pollution (aside from cars) in the isolated mountain valley. The method he applied couldn't have been simpler. From the valley's three hospitals he collected counts of admissions for respiratory illness—before, during, and after the plant shutdown.

And the results could not have been more striking. When the mill was running, hospital admissions were 40 percent higher for bronchitis and 17 percent higher for pneumonia. Especially startling was the effect on preschool children: twice as many admissions for bronchitis and asthma.

IN SHORT

Air pollution, especially tiny particles, kills about 50,000 people in the U.S. each year.

Asthma is aggravated by pollution, but it can be kept under control if you get the right medications and keep your home clear of allergens.

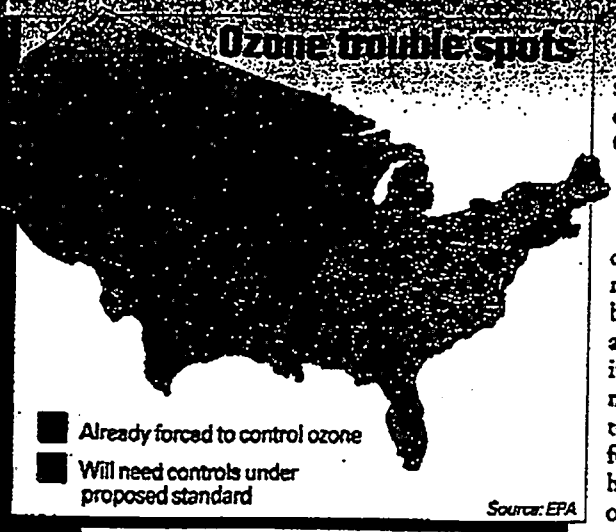
Ratings of high-filtration vacuum cleaners, page 40.

Yet Provo's atmosphere didn't seem particularly bad. Even when the mill was in full operation, the valley's air was only slightly dirtier than national air-pollution regulations allow.

That 1989 study is one of many dozens in the past decade that point to a worrisome new conclusion: Outdoor air—even air that meets present pollution standards—still can be hazardous to your health.

Scientists have detected a sizable and reliable connection between dirty air and health problems in dozens of communities large and small, old and new, in every type of climate, throughout North America.

So consistent is the association that epidemiologists can even estimate the annual U.S. toll from air pollution—about 50,000 deaths from heart disease, asthma, stroke, bronchitis, and the like. That's more people than die in auto accidents. Thousands of these deaths occur in places where air meets current national standards.



"I know of no other environmental risk factor where the exposure is so ubiquitous and the effects are so large," says C. Arden Pope, author of the Provo study.

After considering the evidence of previously unrecognized hazards, the U.S. Environmental Protection Agency (EPA) proposed strengthening air-pollution standards for the first time since 1990. The new regulations, which President Clinton endorsed in June, were expected to be published in July.

The proposal has elicited strenuous protest from industries that contribute most heavily to air pollution: oil, autos, utilities, and heavy manufacturing. Resurrecting arguments shaped during previous clean-air debates, these industries predict that compliance would threaten thousands of jobs and intrude on Americans' lives. They have sent dozens of lobbyists to churn up Congressional opposition.

And employing a tactic increasingly common in health and environmental controversies, industries have launched a direct attack on the science itself. Typical is a Mobil Corp. newspaper advertisement asserting that the link between air pollution and illness is "based on shaky science" that is "unraveling" and "incomplete."

However, a close look at this "shaky" evidence shows that it is anything but. The real debate, in our opinion,

Deceptive Scenic Casco Bay, Me., is downwind of so many ozone sources that—as monitors in the shed in the background reveal—its air violates current standards.

Photo by Joseph Devenney; illustration by Dave Morril

should be over how much air pollution we should tolerate.

Bad air, bad health

Proving a link between environmental pollution and disease is normally a daunting task. But in the case of air pollution and health, scientists have obtained remarkably consistent, significant results no matter where they've looked.

Many of the studies have used a similar technique: They've compared deaths and hospital admissions with air-pollution measurements made by pollution-control agencies.

"All this data is publicly available," notes Joel Schwartz, associate professor of environmental epidemiology at the Harvard School of Public Health and author of many of the studies. "You find people dying from chronic lung disease, pneumonia, and sudden heart attacks. These aren't people [already] lying in the hospital with tubes stuck in them. The biggest increase we find on high air-pollution days is in people dead on arrival at the hospital."

Two significant contributors to these effects are ozone and particulate matter.

Ozone. This is an unstable gas formed in the air by sunlight-induced reactions between two types of emissions, nitrogen oxides from combustion and vapors from sources such as gasoline and solvents. Ozone pollution gets worse when the weather heats up.

Ozone is beneficial in the upper atmosphere, but toxic below. It readily reacts with whatever it touches, which makes it irritating to living tissue. A few seconds in a high concentration of ozone is like opening your eyes in an overchlorinated swimming pool.

Many studies have found harmful consequences:

- Children at a Connecticut asthma camp were 40 percent more likely to have an acute asthma attack on high-ozone summer days than on average days. (Laboratory studies of asthmatic and normal volunteers suggest that ozone magnifies the effect of the allergens and irritants that set off attacks.)
- The first results of an ongoing 10-year study of southern California schoolchildren has found a direct correlation between school absences and lifetime exposure to ozone.
- When healthy volunteers exercise in ozone concentrations like those routinely found outdoors in urban areas, their lung function deteriorates, they develop an irritable cough, and their airways become inflamed.
- Studies in nine major U.S. cities show that daily mortality rates increase along with ozone, even if the ozone is below current legal limits.

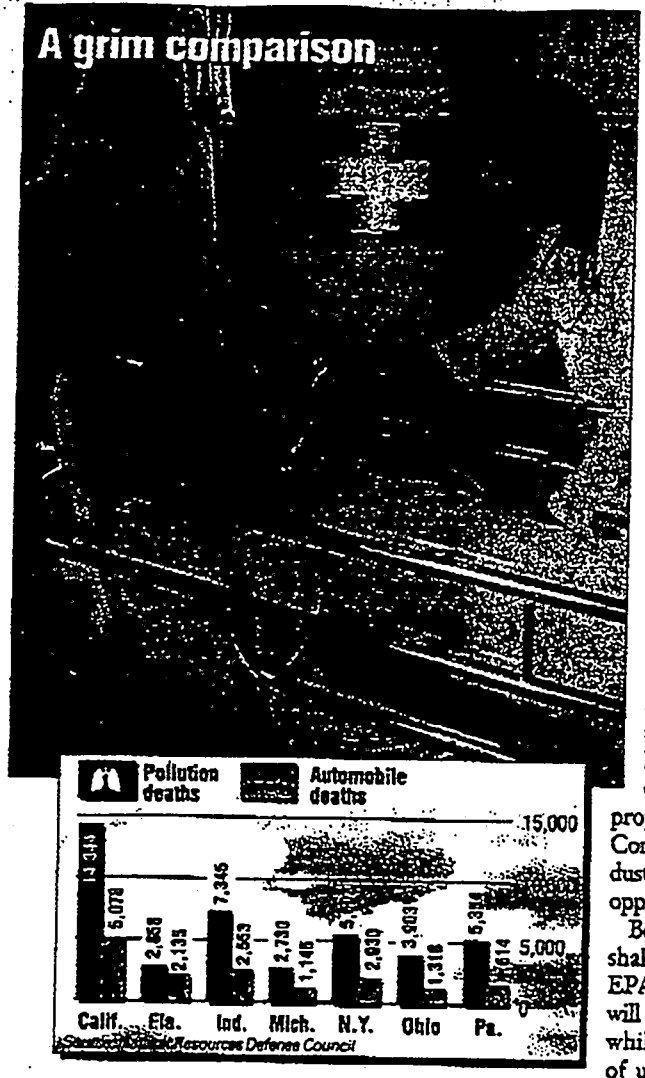
Particulates. These are what they sound like: tiny particles. Much tinier than ordinary dust, they can be inhaled into the deepest recesses of the lung and lodge there for a long time. The most damaging particles, the very smallest ones, usually are by-products of combustion.

Their effects on people have been measured in many cities in the U.S. and in other countries: more respiratory illnesses and more deaths.

- A few weeks ago, researchers reported that infant mortality in the most polluted communities is 25 percent higher than in the cleanest ones.
- A study of 15,000 children in 24 North American communities found that youngsters in the community with the worst fine-particle pollution had 65 percent more bronchitis than those in the cleanest community.
- The most striking evidence comes from the so-called Six City study, in which researchers from Harvard and Brigham Young universities followed more than 8000 adults for an average of 15 years, comparing their health status to local fine-particle counts.

The results: Residents of Steubenville, Ohio, the city with the most small-particle pollution, had a 25 percent higher mortality rate than residents of the cleanest city, Portage, Wisc. The excess deaths were almost entirely from lung cancer and cardiopulmonary disease.

The researchers were so amazed by their findings that they repeated the study using an even larger number of people—500,000 adults in 151 communities. They got similar results.



Laboratory evidence is accumulating as well, says Schwartz, the Harvard epidemiologist. "Three different research groups have now independently reported that these particles produce the kinds of cardiovascular changes suspected in causing sudden death from heart attack."

Tightening the rules

The U.S. passed its most comprehensive air-pollution law, the Clean Air Act Amendments, in 1970. Since then, the air has gotten a lot cleaner in some respects. Still, 121 million Americans—nearly half the population—live in areas where air does not meet existing health-based standards. Nevertheless, the new health studies prompted the EPA to propose even stricter standards for ozone and particulates:

Improved in the past decade, ozone concentrations have declined 6 percent, and particulates are down 22 percent. But air in many areas still violates the standards.

Ozone. The standard, now the equivalent of 0.09 parts per million averaged over an eight-hour period, would be tightened to 0.08 parts per million. (Environmental and respiratory-health groups, such as the American Lung Association, prefer an even lower level—0.07 parts per million.) The expected effect: millions fewer people losing lung capacity and 140,000 fewer cases of acute respiratory symptoms each year.

Roll up the windows. *Study after study shows more deaths and hospitalizations when the air is bad. That leads to such calculations as this one: the number of deaths attributed to particulate air pollution in one year in several states' metropolitan areas, compared with the number of automobile deaths.*

This change would mainly affect heavily populated regions that just barely meet current standards, such as the upper Ohio River Valley and the Carolinas. These areas would likely have to do what regions with even more ozone pollution have already done: Crack down on polluting cars, require gasoline and solvents with less vapor, and—above all—make industries and power plants clean up more of their emissions.

Particulates. The current standard treats all small particles—those measuring less than 10 microns—as one group. It turns out that industries can meet this standard by controlling the largest of the group, such as soot and dust, while doing nothing about the very fine particles—less than 2.5 microns—that scientists now realize do the most damage.

The EPA's proposal would add a specific limit for the very fine particles—an annual average of 15 micrograms per cubic meter, with an allowable 24-hour "peak average" of no more than 65 micrograms per cubic meter. The change would save about 15,000 lives a year and avoid 8000 hospitalizations, the EPA estimates.

This change would have its biggest impact on the coal- and oil-burning industries and utilities and on diesel vehicles, which have largely escaped strict regulation under present rules.

The current debate

Not surprisingly, those very same industries are leading—and bankrolling—a vigorous lobbying and public-relations campaign against the EPA's proposal. Many members of Congress—especially from the industrial Midwest—have taken up opposition to the EPA's proposal.

Besides dismissing the science as shaky, the opponents scoff at the EPA's claim that the new rules will cost less than $9-billion a year while returning health benefits of up to $120-billion. Industry puts the cost at closer to $60-billion—and says the EPA has overstated the value of the lives saved.

"A lot of people argue it needs more study," says Joe Lastelic, spokesman for the American Petroleum Institute. "You shouldn't be spending all that money if you're going to get minimal benefits."

In fact, it is difficult for anyone to predict the cost. Those industries have made the same threats repeatedly over the years, but when regulations have changed anyway, the predicted economic disasters haven't materialized. For example:

- In 1990, industry warned that Federal rules requiring better sulfur-dioxide pollution controls on large power plants (to control acid rain) would cost as much as $1500 per ton of pollution removed, while the EPA predicted $500. Actual cost: $70 to $100 per ton.
- In the 1980s, oil companies resisted changing to a lower-vapor gasoline. "They complained that the cost of gasoline would shoot up 3 to 5 cents a gallon and that there would be long lines at gas stations," recalls Bill Becker, director of the Association of State and Territorial Air Pollution Program Administrators. "Nothing of the sort happened. The cost increase was a fraction of a cent."

Policy analysts say this happens because, when given no choice, companies come up with new technological solutions. In fact, a study commissioned by the American Iron and Steel Institute found that steel mills in the upper Ohio River Valley could comply with the EPA particulate proposal at "minimal cost."

It's also very difficult to put a price tag on the health benefits. There are many different ways of calculating the cost to society of death and illness.

Recommendations

Even if industries' cost of cleaning up exceeds people's cost of breathing dirty air, that's no excuse to do nothing about it.

"Pollution is hideously expensive already," says George Thurston of the New York University School of Medicine's Institute of Environmental Medicine, the author of many air-pollution and health studies. "People are going to the hospital, they're taking medicines, they're taking sick days. What we are really talking about here is transferring the costs from the general public to the polluter."

Unpersuasive. One of the silliest arguments against tighter air standards: We need urban ozone to help shield us from sunlight-induced skin cancer. In fact, the protection is negligible compared to the respiratory damage.

As we said in our report, "Facing Our Fears" (December 1996), the debate on such questions needs to be shaped by public values, supported as much as possible by hard information.

We endorse strengthening the nation's air-pollution standards. The science suggests that the health benefits would be great, history suggests that industry's costs will be less than advertised, and the public has consistently shown that it wants the Government to make sure the air is cleaner.

Pollution linked to hospital stays

Close connection of smog, illness alarms activists

By David R. Baker
Daily News Staff Writer

As smog and soot levels rise in the Los Angeles air, so do hospital admissions for asthma, pneumonia and other respiratory problems, a new study found.

The study, to be released today at an air-quality symposium, tied daily air pollution measurements to patient admissions during 1995 at Kaiser Permanente hospitals, including those in Woodland Hills and Panorama City.

Researchers found that the number of admissions rose in lock step with increases in either ozone levels or the amount of particulates — airborne pollutants far smaller than the diameter of a human hair.

"This is the first study of its kind conducted in the (Los Angeles) Basin and shows that the region's air pollution continues to be a leading public health concern," said Shankar Prasad, health effects officer for the South Coast Air Quality Management District, which paid for the $145,000 study.

Although researchers expected to see some correlation between pollution and hospital admissions, they didn't expect such a significant increase, said district spokesman Sam Atwood.

The study comes just after the AQMD announced the region experienced the least-smoggy season on record.

Local environmentalists called the findings alarming.

"These are people hospitalized simply because they were breathing the air, not because they were doing anything harmful," said Tim Carmichael of the Coalition for Clean Air. "It's a tragic situation, and we've got to do everything we can to change that."

Indeed, the study and the symposium — hosted by the air quality agency — could have far-reaching effects on how Southern California deals with air pollution. After listening to the results of this and other health studies today, participants in the two-day symposium will discuss efforts to cut emissions from what many consider a major source of air pollution — diesel engines.

Although only 4 percent of California vehicles use diesel, those vehicles account for more than 30 percent of nitrogen oxide emissions and even more of the particulate pollution, according to the AQMD.

Two bills that would encourage truck-fleet operators and others to switch from diesel-burning engines were discussed in the state Legislature during the past session. And next year, the state's Air Resources Board will consider listing diesel exhaust as a toxic air contaminant, a step that could lead to further regulation.

Beau Biller, spokesman for the California Trucking Association, said he opposes such a classification because it would leave diesel users vulnerable to lawsuits from people claiming the exhaust made them sick.

The Kaiser study did not look at specific sources of pollution. Instead, it matched ozone levels and particulate emissions throughout 1995 with Kaiser records covering 1.6 million patients.

For every 10 microgram increase in the concentration of particulates, hospital admissions rose an average of 7 percent for chronic respiratory illnesses, 3 percent for cardiovascular disease and 3.5 percent for acute respiratory illnesses.

Ozone had a similarly hazardous effect. During the study, when the ozone concentration in the air rose by 10 parts per billion, an average of 2.7 percent more people with chronic respiratory problems, 5.7 percent more cardiovascular disease sufferers and 1.5 percent more people with acute respiratory diseases checked themselves into the hospital.

ROBERT A. JONES

A Quiz For Deep Breathers

Which of the following statements is true:

• Los Angeles' air pollution gets better year by year, so don't worry, be happy.

• Air pollution is more dangerous to your health, and your children's health, than anyone realized even 10 years ago.

My quiz is a setup, of course. Both statements are true.

Each year the smog levels drop, leaving the view a bit clearer. And each year scientists discover that the remaining filth in the air erodes our lungs in ways no one predicted when the war on smog began.

Nowhere have these paradoxical trends been so displayed as last week in Diamond Bar. The Air Quality Management District, which relentlessly praises its smog-fighting success, released a new study that should scare every parent in the basin and anyone else who has breathed L.A.'s air for long periods.

□

The study, conducted by the Kaiser Foundation Research Institute, found that modest increases in

Please see JONES, B6

Court Files reporter Ann W. O'Neill is on vacation.

JONES

Continued from B1

particulate pollution—we're talking here about construction dust, rubber tire grit and the like—produced sharp increases in hospitalizations at Kaiser hospitals.

Keep in mind that particulates once were regarded as so innocuous that little research was conducted into their impact on human health. After all, it was only dust. The heavy-duty research was directed at the more exotic pollutants such as ozone and nitrogen oxides.

Now we know different. A dozen studies over the past decade have established particulates as one of the most dangerous components in the air pollution mix. They work their way deep into the lungs, where they slowly do their damage. And Southern California, natcherly, has the highest particulate levels in the country.

The Kaiser study showed that the biggest jump in hospitalizations came for those who already suffer from chronic lung diseases such as bronchitis or asthma. If the particulate level rose from 40 micrograms per cubic meter to 50 micrograms—a common occurrence here—the number of hospitalizations among this group increased by 7%.

Shankar Prasad, the health effects officer for the AQMD, called the 7% figure "a big number." And indeed it is, almost twice as large as the increases found in cities back East.

Ronald White of the American Lung Assn. says such figures are sometimes dismissed by those who argue that they apply only to the dying and very sick.

That represents a misconception, he says. "This country has tens of millions of people with chronic lung and cardiovascular disease," White says. "Many of them go to work every day and lead productive lives. They are not lying in bed on a respirator."

And how did these people come by their chronic lung disease in the first place? Some of them smoke cigarettes, of course, or have a genetic predisposition. For others, the culprit may be the same air pollution that eventually delivers a knockout blow and puts them the hospit l.

□

In fact, one of the scariest studi of recent years involves t autopsies of 107 young accide victims in Southern California. described in a report by the Nat ral Resources Defense Council, t study found that 104 of the you people showed early signs of pe manent lung disease. Nearly had chronic low-level bronchit One-third had chronic interstit pneumonia, a form of the disea found deep within the lung tissue

Before their deaths, almost no of the young people showed ou ward signs of breathing disorde In other words, they didn't kno they were developing chronic lu disease. But they were movi inexorably toward that status of person who eventually gets pick off by an uptick in particulates.

"The dilemma is that peop keep hearing about the air gettir cleaner, and it is," says Whit "What they should also hear is th science has learned there's muc more to worry about even wi those lower levels."

As for particulates, the city Los Angeles could strike a quic blow for cleaner air by committir itself to enforcement of the month-old ban on leaf blowers. all of Southern California, son 420,000 leaf blowers now wor furiously to throw as much dust possible into the air so we can a breathe it.

That dust contains desiccate pesticides, animal feces, lead, as bestos and god knows what els And it gets thrown right int people's faces, especially the face of the men who must work wit the machines strapped to the backs.

The leaf-blower ban won't solv the particulate problem by an means, but it's a start. Wouldn't be pretty to think that one day w could drop off our kids at schoo watch them race across the play ground, and not feel that twinge c regret over raising them in th filthiest air in the country?

Ironically the new science ma help us get there. Knowledge i power, after all. If we use i correctly, this knowledge could ge us a long way.

CLEAR THE AIR

...TION for CL... ...air SPR... 1997

Special Edition:

Breathless

Warning: Breathing May Be Hazardous To Your Health

We all have to breathe. Unfortunately, breathing Southern California's air can leave us breathless. The symptoms are all too familiar: coughing, burning eyes, chest pains, wheezing, nausea and headaches.

Scientific studies have consistently linked air pollution to serious respiratory disease, cancer and even premature death. And, a growing body of medical evidence indicates that particulate pollution — tiny, microscopic particles in the air — may be the most harmful of all air pollutants.

For years, government, industry, environmental organizations and the community have been successfully working together to reduce air pollution. Our air *is* cleaner today than it was twenty years ago.

Unfortunately, however, people who live in the South Coast Air Basin — which includes Los Angeles, Orange and parts of Riverside and San Bernardino counties — still breathe the most polluted air in the country. In fact, you would have to combine the air pollution from more than 40 metropolitan areas including New York, Chicago, Houston, Philadelphia and Denver to equal the unhealthful exposure in the South Coast Air Basin.

This special edition of *Clearing the Air* provides an overview of the effects smog has on our health and closely examines the risks associated with particulate pollution.

Please read this and share it with your friends and family. It's filled with valuable information to help protect you and your family. Everybody has to breathe. It shouldn't hurt us to do it.

The Facts:

Every year approximately 8,700 people die prematurely from exposure to particulate matter pollution in the South Coast Air Basin alone, according to NRDC.

Children raised in Southern California have a reduced lung capacity compared to children raised in other cities such as San Francisco, Seattle or Houston.

Breathing air in Southern California can reduce one's life span by one to two years.

Asthma is the leading serious chronic illness among children in the U.S. and is the #1 cause of school absences.

A Serious Health Threat

What is PM? PM, or particulate matter, is air pollution in the form of very tiny particles that float in the air. It can be solid pieces or tiny liquid droplets that form from other kinds of air pollutants. Depending upon where you live, it is likely a combination of both. It can ruin our view by reducing visibility — but, most importantly, it is a serious threat to human health.

PM makes healthy people sick and can make sick people die prematurely. In fact, PM is probably the most harmful of all air pollutants. It affects more than 70 million people nationally and more than 20 million people in Arizona, California and Nevada.

Of greatest concern to public health are the particles small enough to be inhaled into the deepest parts of the lung. Normal body defense mechanisms, like coughing or sneezing, don't help to clear the particles from our lungs. These particles are less than 10 microns in diameter, about 1/7 the thickness of a human hair.

Health Effects

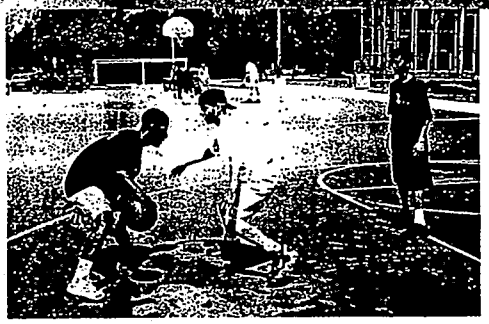
PM pollution causes serious health problems in people of all ages, although children and the elderly are most sensitive to PM. It causes respiratory disease, aggravates asthma and bronchitis and reduces lung function. It reduces our ability to fight infection. It can cause cancer. Most importantly, it can cause premature death in the elderly and people who already have heart or lung disease. These impacts result in more doctor and emergency room visits and more work for our health care system.

Facts About PM

Where Does It Come From?

PM can be any number of things. It's a grab bag of pollutants and it comes from many sources: from truck and automobile tail pipes; from oil refineries and power plants; from chimneys of wood-burning fireplaces and stoves; from brush and waste burning; and from exposed dry ground construction and agricultural activities. It is smoke, organic compounds, salts and heavy metals such as lead. It is cancer-causing agents as well as toxic chemicals. It is dust blown from cleared land, construction sites, storage piles and the sides of ditches and roads. PM is dirt tracked onto paved roads and thrown into the air by passing cars. Ever wonder what happens to the tread from your tires? PM is even rubber pieces from automobile tires and metal pieces from brake wear. PM comes from many places but for the most part, it is caused by human activity. We produce more than 420 tons of PM every day in the South Coast Air Basin simply by going about our business as usual. That is why it is up to all of us to do something about it.

> **"PM is probably the most harmful of all air pollutants."**



What Can PM Do?

The Natural Resources Defense Council (NRDC) calculates that approximately 64,000 people in the U.S. will die prematurely each year from exposure to particulate matter. 8,700 of these deaths occur in Los Angeles, Orange, Riverside and San Bernardino counties.

What Can I Do?

Read the next page, "Are You at Risk?" and "What You Can Do" (p.5) for tips on protecting yourself, your children and the air. Read the enclosed poster and keep it on your refrigerator. Most importantly, get involved! Call the Coalition for Clean Air to find out how you can help.

Are You At Risk?

Are you...
- a child
- elderly
- an infant
- an athlete

?

Do you have...
- allergies
- asthma
- heart disease
- chronic illness

?

Then you may be at extra risk.

Help yourself. Help your family.

Use air conditioning and air filter systems whenever possible.

Do not exercise outdoors on smoggy days.

Do not exercise during peak smog periods.

Check pollution levels in your area.
It's a toll free call to the South Coast Air Quality Management District. (see p.5)

Talking to Dr. Gong

Dr. Henry Gong is a Professor of Medicine at the University of Southern California School of Medicine and is Chairman of the Department of Medicine at the Rancho Los Amigos Medical Center.

People who live in Southern California breathe the dirtiest air in the country. We know that air pollution is bad for our health. Just how bad is California's smog for us?

There's been a noticeable reduction in air pollution over the past five years, especially in the number of Stage I Smog Alerts. Still, we have a significant amount of background ozone. In 1996, the days on which federal standards were exceeded were almost one-third of the year.

I hope that downward trend continues. However, it's possible — because of politics and legislation — that important regulations might be relaxed. This would result in more air pollution.

Lately we've been hearing a lot about particulate matter pollution. We hear that it may cause the most serious damage to our health. Please tell us what particulate matter is. Is it different from traditional smog? If so, how?

Particulate air pollution consists of fine, invisible particles that are easily inhaled into our lungs. Particle pollution consists of many substances, including road dust, sand, acids and metals.

Traditionally, in Southern California we have focused on the health effects of ozone pollution. Indeed, ozone is still a major problem in Los Angeles. However, particles and other pollutants are part of this mix in our air. Our concentration has shifted from time to time. Particle pollution has always been there. In the 1990's we have become more concerned about particulate pollution. In fact, because of premature death, asthma,

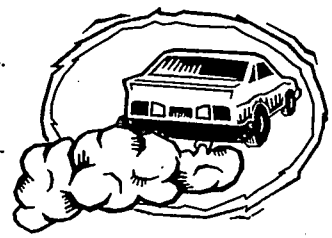
Dr. Henry Gong

breathing symptoms and other lung ailments, some experts view particulates as the most toxic of the air pollutants we measure.

How exactly do particles cause harm to human health?

We don't know how particles (particulates) harm our lungs. We're not sure if it's the total amount or the chemical type of particles that are responsible for adverse health effects.

Specifically, particles produce irritation of the airways and enhance asthma attacks or interfere with proper lung or heart function in more vulnerable persons. This occurs by processes involving immune cells or overloading the lung's defense mechanism.



What are the most common and most dangerous health effects of particulates?

The most common health effects associated with breathing particles are respiratory symptoms in healthy persons such as coughing and chest tightness. And, they can cause wheezing in asthmatics. Serious breathing or heart problems caused by breathing particulate pollution may require one to see a doctor or be hospitalized.

The worst outcome is death. Epidemiologists have used death certificate information to determine that there are excess deaths associated with particulate matter pollution. In fact, the Natural Resources Defense Council has estimated that 64,000 people in the United States die each year because of particulate pollution.

Is there a cause and effect relationship between particulates and ill health or premature death?

So far, there is a strong, consistent and coherent association between particulate matter pollution and ill health and premature death. This

cont'd on page 7

Dr. Gong (from p.4)

association is based on numerous health risk studies of different groups of people, different ages, different cities conducted by different researchers. While we do not currently have a definite cause and effect relationship, there is weight of evidence which strongly indicates that there is a relationship.

Who is at greatest risk?

Elderly persons with chronic heart or lung illness and children receive the brunt of the effects of particulate pollution. Asthmatics of all ages are also at risk.

What level of exposure to particulates is considered unhealthy?

Concentrations above the current federal standard for PM indicate damage to lung health and life. Despite improved air quality today, there continues to be a finding of a direct or linear relationship between particulate matter concentrations and death. That there is not a known safe threshold level is of greater concern. In other words, we don't know if there is a safe threshold level. This means that even the current federal standard for PM may be insufficient for protecting public health.

What can we do to protect ourselves from particulate pollution?

Learn more about air pollution and its health effects. Support legislation aimed at improving air quality; support the use of clean, alternative fuels that pollute less than gasoline and diesel; and support research aimed at learning more about the health effects of PM pollution. During smog alerts or increased outdoor pollution, limit the time you spend outdoors; reduce your level of outdoor exercise; and exercise in the morning or evening. Also, use prescribed inhaled medication, if applicable, prior to going outside. Consider wearing masks with activated carbon filters and consult the air quality charts in local newspapers to see where and when air quality is predicted to be worse or better. Last, use air conditioners. You can probably remove most outdoor air pollution before it enters the home, which is desirable.

Special thanks to: The American Lung Association, Clean Air Network, Natural Resources Defense Council, Dr. Henry Gong, Lee Schneider, Toni Pogue and the PM 10 Best Available Control Measures Working Group.

Coalition for Clean Air Mission:
The Coalition for Clean Air is dedicated to restoring clean, healthy air to Southern Californians by organizing broad-based community involvement, advocating responsible public health policy and providing a source for technical and educational expertise.

Printed on recycled paper using soy-based inks

The South Coast Air Basin—which is Los Angeles, Orange and parts of Riverside and San Bernardino Counties, has the dirtiest air in the whole country.

To help keep you, your family and friends safe, please use this poster. Follow the tips inside—they really work!

If you have any questions about this information, please call the Coalition for Clean Air at 310.260.4770.

SOUTHERN CALIFORNIA'S SMOG: HARMFUL IF SWALLOWED

Southern California still has the dirtiest air in the country.

You would have to combine the air pollution from more than 40 metropolitan areas in the country, including New York, Philadelphia, Chicago, Denver and Houston, to equal the unhealthful air quality in Southern California.

Residents of the South Coast Air Basin (which includes Los Angeles, Orange and parts of Riverside and San Bernardino counties) breathe dirty air an average of one out of every three days.

Medical studies indicate that smog has short- and long-term effects on our bodies.

Women living in high particulate areas may have

While air pollution affects everybody, its effects are more severe on sensitive populations, including:

Infants & Children
Teenagers
Pregnant women
The elderly
Anyone who suffers from heart or lung disease or respiratory problems such as asthma
Healthy people who exercise vigorously.

Children probably suffer the most from smog:

Children raised in Southern California suffer a decrease in lung function compared to children who grow up in less-polluted cities such as Seattle, San Francisco or Houston.

Children are more susceptible because they breathe more and faster than adults and their bodies and lungs are still developing.

8,700 premature deaths in Southern California are linked to particulate matter each year, according to the NRDC.

It will take all of us working together to help us breathe a little easier.

Call the Coalition For Clean Air for more information or to help. 310.260.4770

Breathing Particulate Matter, Ozone, Carbon Monoxide, and Nitrogen Oxides causes:
Burning eyes
Coughing/wheezing
Chest pains
Headaches/Nausea
Lung damage
Tired feeling
Respiratory infections.

Fine Particles (PM) may be liquid droplets or solids—a mixture of human-made and natural substances. PM is finer than the width of a human hair. Certain types of PM can increase the risk of developing cancer.

PM makes healthy people sick and can make sick people die prematurely. In fact, PM is probably the most harmful of all air pollutants. It affects more than 20 million people in Arizona, California and Nevada.

Of all the pollutants in the air, those smaller than 10 microns (about 1/7 the size of a human hair) are the most dangerous. When PM is that small, we breathe it in, but we can't breathe it back out again. It gets stuck in the deepest part of our lungs and stays there. Normal body defense mechanisms, like coughing or sneezing, don't help.

Help yourself. Help your family. Help your friends.

- Do not exercise outdoors on smoggy days or during peak smog periods.
- Use air conditioning and air filter systems whenever possible.
- Avoid scheduling outdoor games and activities during smog episodes.
- If you have asthma, take your medication before going outdoors.

Check pollution levels in your area. It's a toll free call to the South Coast Air Management District (see below).

Natural Resources Defense Council

About NRDC

NRDC is a national nonprofit organization dedicated to protecting the world's natural resources and ensuring a safe and healthy environment for all people. With more than 350,000 members and a staff of lawyers, scientists, and other environmental specialists, NRDC combines the power of law, the power of science, and the power of people in defense of the environment.

Editorial Purpose

The Amicus Journal is a quarterly of thought and opinion for the general public on environmental affairs, particularly those relating to policies of national and international significance. In keeping with NRDC's program of public-interest advocacy and its efforts to educate the public about environmental protection, this magazine offers essays, news analysis, features, profiles, reviews, and poetry; it also integrates news about NRDC, its staff and their work, with news about the environmental movement as a whole. To stimulate a creative exchange of ideas, **The Amicus Journal** is open to diverse points of view and belief; the opinions and views expressed in its pages (except those devoted to NRDC) by contributors and the editors are their own and not necessarily those of NRDC.

Amicus

Amicus (əmēkəs) is Latin for "friend." Its most common usage is in the phrase *amicus curiae*, meaning "friend of the court," an outside party who can comment on a lawsuit. NRDC has played this role on many occasions as an advocate for the environment.

Clearing the air

An epidemiologist takes on the worst air pollution problems of our time

by Renée Skelton

Joel Schwartz is clearly enjoying himself. Eyes lively, smile broad, he teases, jokes, hops across the front of the classroom to make a point, and endures the posturing of even the most annoying class showoff with good humor. This is "Advanced Regression Techniques for Environmental Epidemiology," and Schwartz is explaining how to mathematically filter out confounding factors in epidemiological data. Whether or not they're aware of it, the eighteen students packed into this small classroom are learning from one of the most eminent epidemiologists and biostatisticians in the United states today—a man who has been in the forefront of scientific research on two of the most important environmental health issues in recent years.

Now a professor at the Harvard School of Public Health, Schwartz spent his early career at the Environmental Protection Agency (EPA) during the environmentally challenged administrations of Ronald Reagan and George Bush. He gained a reputation for going the extra mile to explore the environmental health impacts of public policy decisions, sometimes even against the preferences of his superiors. His efforts were a major factor in establishing the final phaseout of lead from gasoline in the mid-1980s. Today, in one of the hardest-fought public health battles in U.S. history, he is one of many environmental health experts urging EPA to resist an avalanche of industry pressure and tighten the standards for fine airborne particles—currently the leading air pollution health threat in the country.

Schwartz began his scientific career in theoretical physics—great training, he says, in learning how to think—and entered the public policy arena as then-Representative Tim Wirth's legislative assistant for energy and the environment in 1977. In 1979

Harvard School of Public Health

Harvard's Joel Schwartz has done groundbreaking work on lead and particulates.

he joined EPA, where he worked at first on energy issues. But a brewing fight over the program to reduce the lead content of gasoline would become the central focus of his work for the next few years.

"When Ronald Reagan got elected, they set up a task force on regulatory reform, which put out a press release soliciting industry to nominate burdensome government regulations that ought to be abandoned," Schwartz remembers. "Since the basic screening protocol, as far as I can tell, was the number of letters they got that didn't like the regulations, [the lead phasedown] was right up there on their list."

In 1973, after a lawsuit brought by NRDC, EPA had created a five-year program to gradually reduce gasoline lead content. At the time, tetraethyl lead (TEL) was routinely added to lower-grade gasoline to make it burn efficiently enough to prevent the small explosions ("knock") caused by uneven combustion. For decades, the nation allowed the combustion of leaded gas to spew millions of tons of lead into the air, where it was breathed in or deposited in soil and dust.

But unlike many elements that are valuable at trace levels, lead is toxic, even in the smallest amounts. "Lead has absolutely no physiological function," notes physiologist Evelyn Mauss, who has been active in lead reduction efforts for several years. "Earliest human beings had almost no lead in their bodies. We didn't accumulate lead until it began to be mined out of the crust of the earth." Children with elevated blood-lead levels can suffer lower IQ, slower neural transmission, hearing loss, and disruption of the formation of hemoglobin in red blood cells. Acute lead poisoning wreaks massive physiological damage.

In the early 1970s, leaded gasoline was believed by many to be a route for lead exposure, but the connection was not yet proven. NRDC had had to bring its lawsuit for a lead phasedown on the grounds that it damaged catalytic converters and made other kinds of air pollution reductions difficult. By mid-decade, however, several leading environmental health scientists—notably Philip Landrigan, Paul Mushak, Herbert Needleman, Sergio Piomelli, Routt

---

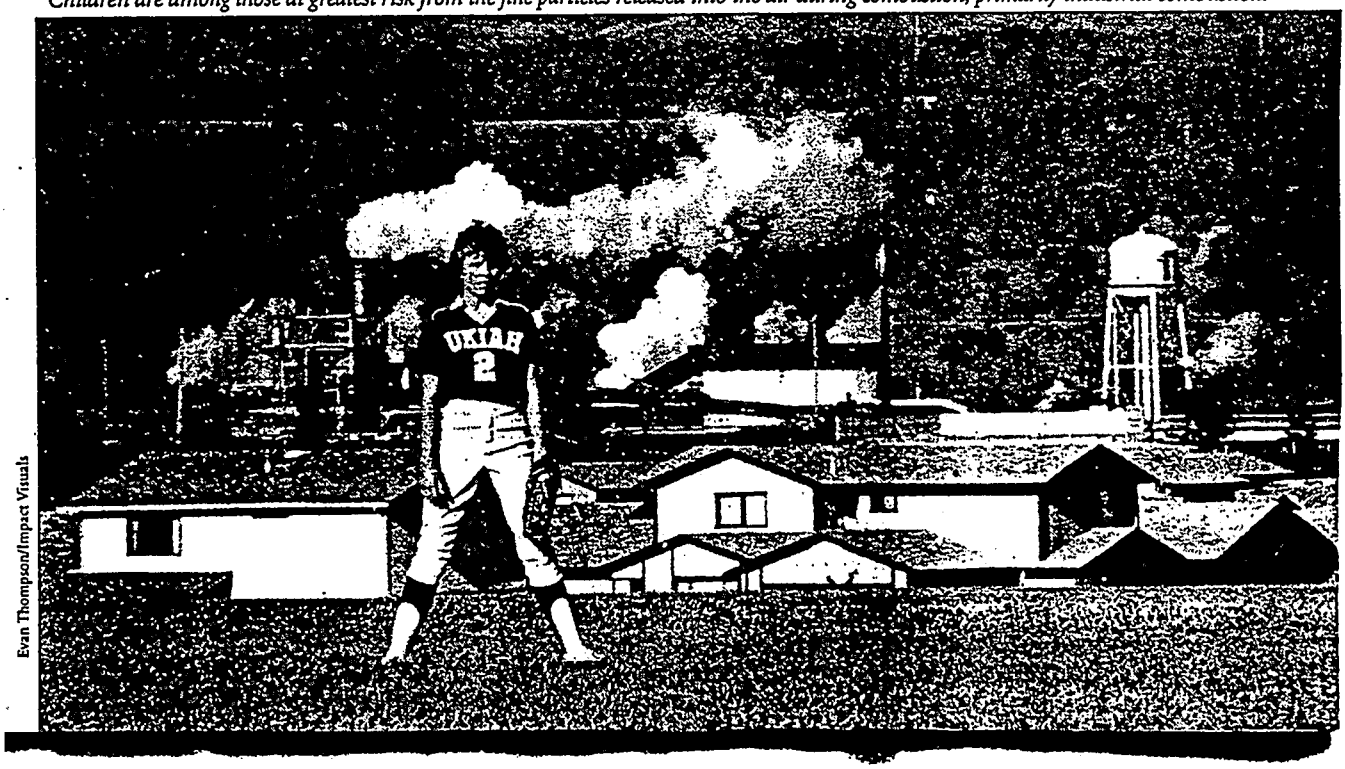
Freelance writer Renée Skelton often covers health and the environment.

Reigart, and Ellen Silbergeld—had begun working to establish the physiological links between lead in gasoline and health problems in children.

But when Ronald Reagan took office in 1981, small refiners decided to ask for a complete abolition of the phasedown. And they got their wish. "We were told to propose getting rid of the lead standards," Schwartz recalls. His assignment was to calculate the cost of the standards to the refinery industry. But Schwartz remembered reading a study showing that the average blood-lead level of children in a New York City screening program precisely tracked the average amount of lead in gasoline for the New York metropolitan area. "So I asked around: 'Who's looking at the health end?' And everybody said, 'Not me, boss!'" Schwartz decided that, since the phasedown was under attack as a burdensome regulation with costs that outweighed benefits, he would not only start collecting health data, but also try to calculate the cost savings of reducing lead in gasoline.

When EPA formally proposed ending the phasedown in February 1982, reaction was swift and almost universally negative. Written testimony poured in from physicians, environmentalists, and public health experts. Congress held hearings; legal action was threatened. The Centers for Disease Control (CDC) reported that the decline in Americans' blood-lead levels since 1976 was directly attributable to the phasedown. Inside EPA, Schwartz's health and cost data were essential information in the agency's own reassessment. And by October, EPA had done a complete about-face: it proposed *strengthening* the lead standards.

Then, in 1985, EPA proposed even stricter regulations, with the goal of eliminating lead in gasoline entirely by the mid-1990s. Two main factors drove this development. One was new health data showing adverse effects at blood-lead levels previously accepted as safe. The other was Schwartz's analysis, which showed that it would cost industry about $575 million to meet the newest lead standards by 1986—but also that that sum was dwarfed by the $1.8 billion that would be saved during 1986 alone through reduced needs for medical care, lower pollution emissions from lead-damaged catalytic converters, reduced needs for vehicle maintenance, and greater fuel efficiency.



As of 1994, the CDC estimate is that 1 million children under six have blood-lead levels exceeding its threshold of concern. But the number is much lower than it used to be. And, looking back on Schwartz's career from the vantage point of 1991, then-EPA Administrator William Reilly commented, "Every time you fill up your car with gasoline, you can think of Joel Schwartz."

Schwartz's work on lead convinced him that he wanted to continue with epidemiology. "It's a calling," he explains. "Not in the sense of religion. But I think the old Protestant viewpoint that you should find your calling and do it has a bit of attraction.... That's not to say that a Pentium processor doesn't change the world. But there does seem to be a more direct line to the health and welfare of people, doing epidemiology."

Colleagues of Schwartz concur that he made the right choice. "He brings an extraordinary creativity to looking at complex data sets, and a real sense of how to make sense out of numbers," says Ellen Silbergeld, who teaches epidemiology at the University of Maryland Medical School. Indeed, in 1991 Schwartz won a MacArthur Fellowship, the prestigious "genius award" given annually by the John D. and Catherine T. MacArthur Foundation to several of the most creative and outstanding people in various fields.

The MacArthur Fellowship was

Children are among those at greatest risk from the fine particles released into the air during combustion, primarily industrial combustion.

Evan Thompson/Impact Visuals

still far in the future, however, when Schwartz finished his work on leaded gasoline and began looking for the next topic to investigate. He settled on air pollution. His reasoning: "Everyone breathes the air, and everyone is exposed to air pollution. It seemed like that's where the bodies were going to be."

He had good reason to think so. There had been several major air pollution disasters during the early part of this century—Meuse Valley, Belgium, in 1930; Donora, Pennsylvania, in 1948; London in 1950—that demonstrated that extremely high concentrations of air pollution could kill large numbers of people. By the late 1980s, there was growing evidence that the particulate matter (tiny suspended particles of soot, soil, mineral, or metal) in this pollution was closely associated with the illnesses and deaths.

Airborne particles are of different sizes and have several sources. The smallest particulates currently regulated by the federal government have a diameter of 10 microns or less; they are referred to as PM_{10}. The largest of these are dust and dirt. But it is $PM_{2.5}$, the smallest particles of all, that pose the greatest threat to health. These extremely fine particles are small enough to evade the body's clearance mechanisms and penetrate deep into the most sensitive areas of the lungs. Moreover, they are mostly the byproducts of combustion—in coal-fired power plants, industrial boilers, highway vehicles, and other sources—and many chemicals formed during combustion are themselves hazardous to health.

In 1971, EPA had put out its first air quality standard for particles, limiting the concentration of Total Suspended Particulates (TSP) permitted in air pollution—not only PM_{10}, but everything larger as well. But by the end of the decade, it was becoming increasingly clear that it was the smallest particulates in TSP that were most closely associated with health risks. In the wake of such evidence, EPA was preparing to set a new standard in the mid-1980s.

Schwartz had been doing some air pollution studies of his own when, in 1986, EPA's air pollution office asked him to analyze data covering fourteen winters of daily deaths and daily air pollution levels in London. Schwartz found the data in this and other studies intriguing. "It looked like there was an association between air pollution and daily deaths," he recalls, "and it looked like it was more the particles than the sulfur dioxide." Furthermore, "what I was seeing was that there was no threshold for this mortality effect." In other words, people were dying even at the lowest concentrations. And this was news. "EPA made believe at the time that there were thresholds for the health effects of air pollution," says Schwartz. "Clearly, they weren't going to set a very tight particle standard unless there was more evidence. So I figured it would be worth doing more stuff to look at whether particles were really associated with daily deaths."

Particulate air pollution is closely associated with illness and premature death.

EPA did set a PM_{10} standard in 1987, the first-ever limit on fine, inhalable particles. But there was increasing evidence that an even tighter standard was needed, and it was far from clear that EPA was ready to face up to that task. In general, "everybody was talking about the cost," Schwartz says. "There was one guy who thought we were spending too much money on air pollution. He said, 'Everyone knows there are no health effects below the ambient standard.'" In fact, the opposite was true, and for Schwartz it was something of a turning point. "That sort of convinced me that the time had come. We were finding effects [below the standard], yet we were getting all this nonsense. It occurred to me that if all decision-making was going to get poisoned by this, then I needed to move up my agenda on particulate air pollution."

Schwartz's strategy was to start "pumping out studies" as quickly as possible—"working very hard to dump out a lot of papers very fast, on the ground that if I just kept on pounding this out in the literature, people could not ignore it."

Schwartz did become incredibly prolific, releasing a number of important studies on the health effects of particles during the late 1980s and the 1990s. The papers, notes NRDC air pollution specialist Deborah Shprentz, were structured "so that each study answers the next question. If there were questions raised by one study about the effect of climate, for example, he'd develop the next study to address that." A number of other scientists, especially C. Arden Pope of Brigham Young University and Douglas W. Dockery of Harvard—who are widely acknowledged, along with Schwartz, as the leading researchers on particle pollution—were also publishing ground-breaking work on the issue. Scores of studies were coming out, and they showed strong associations between fine particle pollution and premature deaths, as well as hospitalizations for respiratory and cardiovascular problems.

Then, in 1991, Schwartz received the MacArthur Fellowship for his work on lead and particles. The nomination process is very secretive; Schwartz had had no idea that he was even under consideration. He was on vacation in Australia when a *Washington Post* reporter phoned him with the news. He was shocked, and, according to a press account of the time, quite speechless. "My first reaction," he says now, "was, 'Well, at least EPA won't be able to fire me!'"

The $275,000 award gave Schwartz the financial freedom to think seriously about making a job change. "It was getting harder and harder to get work done at EPA," he explains. "There were people who didn't like that I was finding health effects of air pollution at low levels." And so he applied for and won the position at Harvard.

In the meantime, the particulates

fight was heating up. EPA had seemed in no great hurry to review its particulate standards in light of the new evidence, as required by law, so the agency got a push from an American Lung Association lawsuit in 1993. That suit started EPA on a tortuous scientific and political process. As it was playing out, further studies gave weight to the thesis that the lives of thousands of Americans are being shortened by a year or two, on average, through exposure to particulates at levels well below the current standard.

In December 1993, Douglas Dockery and other Harvard School of Public Health researchers released the Harvard "Six City" study, which tracked the health of more than 8,000 people for fourteen to sixteen years; it showed that fine particles increased the risk of premature death for residents of the most polluted city by 26 percent over that for residents of the least polluted city. Two years later, the American Cancer Society Study, which tracked about 500,000 people in 151 cities, reported that people living in areas most polluted with fine particles had a 17 percent greater risk of mortality than those in areas with the lowest levels. And in 1996, the NRDC report *Breath Taking* applied these findings to 239 cities, and found that approximately 64,000 people may die prematurely from heart or lung disease every year due to particulate pollution.

Then, at long last, after reviewing hundreds of scientific studies, EPA proposed a tougher particulates standard in November 1996. It included the first-ever standard for the finest, most dangerous particulates, $PM_{2.5}$. But there is no knowing whether the $PM_{2.5}$ standard will survive in the final version, to be released on July 19.

Sitting in his small, cluttered office, fourteen floors above the streets of Boston's Back Bay, Schwartz contemplates the heavily politicized process of protecting the public health. One in four Americans is believed to be especially at risk from fine particles, including children (among them 5 million with asthma), the elderly, and people with heart or lung diseases. For this reason, many physicians and environmental health experts are backing the new standards; fourteen hundred doctors and other health professionals have signed a letter to President Clinton in support. However, EPA has endured an onslaught of pressure from industrial interests.

"They don't want to be regulated, and they have a semi-infinite amount of money," Schwartz says. "They're paying people to attack the studies and say the science is no good."

Since releasing its standard, EPA has endured an onslaught of pressure from industry.

One active player is the National Association of Manufacturers, which includes representatives of the oil, mining, auto, chemical, steel, and electric utility industries. It is leading a coalition of more than 600 members in a multimillion-dollar campaign. Often working through groups with benign-sounding names, such as Citizens for A Sound Economy, they argue that the tighter standards are unnecessary and costly and will jeopardize American freedoms. One radio ad, which ran for a time in Chicago, featured a son talking to his father about his fear that the standards would cost him his job. Then this exchange took place:

Son: *These new regulations would drive up the price of cars, force people into car-pooling, maybe even end up banning things like barbecue grills and lawnmowers.*

Father: *Force us to change the way we live, huh?... Amazing, since it can't be justified for health reasons.*

Politically, Schwartz observes, the campaign is "scoring some points. But so far, EPA has actually been hanging tough." He is cautiously optimistic that a new $PM_{2.5}$ standard will in fact emerge in July when the dust clears. But the outcome is by no means assured. According to an EPA spokesperson, even if the White House does issue EPA's new $PM_{2.5}$ standard, the Small Business Regulatory Enforcement Fairness Act of 1996 will allow Congress to review and possibly block the standard.

"Industry has lobbyists crawling all over down there [on the Hill]," says Robert Musil, executive director of Physicians for Social Responsibility. "But we're convinced that if we can get the message to the American people that the standards will protect health and save lives, it will be difficult for members of Congress to say, 'I don't care if people die. I just care about local industries.' After all, we're not just talking about slightly bluer skies and less sooty laundry."

Schwartz is still engaged in the particulates issue, testifying at hearings and appearing at news conferences to explain the science. However, with the scientific understanding of particulate pollution now largely in place, he is moving on to new projects in epidemiology. His next will be on water pollution.

"Waterborne disease was a very big source of mortal illness in the U.S. decades ago—typhoid, cholera. We've cleaned up water supplies, but are there residual sources of waterborne disease?" Schwartz asks. "It's either a big issue or small potatoes. We don't know. But it has never been looked at systematically. So we're gearing up to do a pilot project."

As long as there are major environmental health questions that need solving, chances are Joel Schwartz will be part of the quest for answers—probably making waves along the way. "This is different [from] doing research on semiconductors," Schwartz says of epidemiology. "You're trying to find out what makes people sick. To me, that should be coupled with a willingness to go out and make people aware about it enough that they do something about it." •

Dear Mr. Nelson:

Second Supplemental Review of Slope Stability of the Proposed Phase II Development for the Sunshine Canyon Landfill County Extension

INTRODUCTION

This memorandum presents the results of a supplemental review of slope stability analyses prepared for the proposed Phase II Development for the Sunshine Canyon Landfill County Extension. This supplemental review follows two earlier reviews for the subject landfill:

- **"Review of Seismic Slope Stability of the Proposed Sunshine Canyon Landfill County Extension,"** memorandum to Rodney Nelson from Leslie F. Harder, Jr., December 26, 1995.

- **"Supplemental Review of Seismic Slope Stability of the Proposed Sunshine Canyon Landfill County Extension,"** memorandum to Rodney Nelson from Leslie F. Harder, Jr., April 29, 1996.

The principal focus in the two earlier reviews was on stability issues affecting the Phase I development of the proposed landfill project. The earlier reviews found that the proposed designs for the Phase I development had adequate static and seismic stability. In the April 29, 1996 review, preliminary analyses of the proposed Phase II development were also examined. The preliminary evaluation performed in that review concluded that an adequate design was possible for the Phase II development provided that three-dimensional effects were properly included in the stability analyses.

Since the April 29, 1996 review, new static and seismic stability studies have been provided in support of the proposed Phase II landfill development (see Figure 1 for project plan). The new analyses for the Phase II construction are the subject of the current review. This supplemental review of the Phase II development was verbally requested by you and is authorized under Interagency Agreement No. B165496 between the Water Resource Control Board and the Department of Water Resources.

The new slope stability information in support of the Phase II development was provided in the studies and reports prepared by GeoSyntec Consultants for Browning-Ferris Industries of California, Inc. The Phase II development will contain a mix of both interim and permanent slopes. However, the studies completed by GeoSyntec Consultants generally treat interim slopes as permanent for the purposes of the stability analyses.

The static and seismic stability issues examined in the supplemental review for the Phase II development were as follows:

- Earthquake loading.
- Dynamic response analyses.
- Shear strengths of municipal waste and liner interfaces.
- Slope stability analyses.
- Displacement analyses and results.

In summary, the current review found that GeoSyntec Consultants had generally employed reasonable and/or reasonably conservative parameters in performing the analyses. However, a significant error was found in one of the GeoSyntec analyses for the permanent slope leading to the stability berm (Section F-F). Consequently, the actual factor of safety is much lower than that determined by the GeoSyntec analyses and the predicted amount of earthquake-induced deformation for this section is also higher than what would be considered acceptable. This might be resolved by properly accounting for three-dimensional effects as was recommended in my April 29, 1996 review memorandum. However, this has not yet been done and needs to be completed to resolve the stability issues that the stability computational error has created.

The additional materials reviewed and comments on specific stability issues are presented in subsequent sections of this memorandum.

SUPPLEMENTAL INFORMATION REVIEWED

The additional materials examined for this supplemental review were contained in the following reports and correspondence:

- **"STATIC AND SEISMIC STABILITY ASSESSMENT - SUNSHINE CANYON LANDFILL COUNTY EXTENSION - PHASE II CONSTRUCTION,"** report prepared for Browning-Ferris Industries of California, Inc.; Sunshine Canyon Landfill District, November 11, 1996.

- **"Supplemental Information on Seismic Response and Stability Analyses for Phase II Grading Design, Sunshine Canyon Landfill County Extension,"** memorandum from Ed Kavazanjian, GeoSyntec Consultants, to Dr. Les Harder, P.E., California Department of Water Resources, April 26, 1997.

EARTHQUAKE LOADING

Previous analyses by both GeoSyntec and the Department of Water Resources have shown that the critical seismic loadings come from potential large earthquakes (e.g. Magnitudes 6.9 - 7.5) that might occur on thrust faults within 10 kilometers of the landfill site. To represent these loadings, GeoSyntec has chosen two accelerograms for use in the dynamic response analyses:

- The Seed-Hayward Synthetic motion (M=7+) developed by H. Bolton Seed and scaled to have a peak acceleration of 0.7g. [This motion was one of the ones suggested for use by DWR in the previous reviews].

- The C-3 Synthetic motion (M=6.7) developed by Dr. W. Silva and scaled to have a peak acceleration of 1.06g.

Both of these accelerograms, when scaled at these peak accelerations, have adequately high spectral content and duration of shaking. The spectral accelerations of both motions at a period of 1 second exceeds 0.8g and would satisfy criteria for both the Maximum Probable Earthquake and the Maximum Credible Earthquake. Accordingly, the use of these two motions for analyzing the Phase II development is considered adequate.

DYNAMIC RESPONSE ANALYSES

The state-of-practice for conducting dynamic response analyses of landfills remains both rapidly changing and uncertain. The dynamic properties used by GeoSyntec two years ago for the Phase I studies (Kavazanjian et al., 1995) are no longer supported. Instead, GeoSyntec now advocates using properties recently developed by backanalyses of the response of the OII landfill. However, two other studies (Idriss et al., 1995 and Augello et al., 1997) also used backanalyses of the OII landfill response and obtained very different sets of properties.

The GeoSyntec analyses for the Phase II development also employed two-dimensional dynamic response analyses (Program QUAD4M) rather than one-dimensional dynamic response analyses (e.g. Program SHAKE) that have been the traditional state-of-practice. Although the use of two-dimensional dynamic response analyses is theoretically more correct and thus preferable, its use will probably lead to lower average accelerations in the waste mass being computed because this type of analysis can incorporate some of the effects of incoherence in the response of the waste mass over large distances. This in turn will complicate some of our judgements because most of our experience in back calculation of in situ landfill and liner strengths (e.g. Augello et al., 1995) have generally relied upon the use of one-dimensional response analyses.

The current review for the Phase II development examined the responses for Sections F-F and G-G calculated by GeoSyntec using QUAD4M for the two critical accelerograms (Seed-Hayward and C-3 Synthetic motions). The results showed relatively high peak accelerations computed at the top of the waste fill, typically between 0.6 and 1.3g. The peak average accelerations for potential sliding masses in Section G-G were generally high, typically between 0.33 and 0.41g. However, the peak average accelerations for potential sliding masses in Section F-F were only about 0.26g. Presumably, the lower average acceleration for the southeast mass in Section F-F is associated with its very long length and incoherence effects along that length. However, it is not certain why the northwest mass in Section F-F was also so low as it has thicknesses and lengths comparable to those in Section G-G. Further, the peak accelerations at the surface of Section F-F are higher than those calculated for the surface of Section G-G.

The QUAD4M dynamic response analyses generally seem reasonable, with the exception of the low average accelerations calculated for Section F-F. In light of the uncertainties and the results from previous studies, including those by Makdisi and Seed (1978), it seems prudent for the evaluation of the Phase II development to use average peak accelerations in potential sliding masses of at least 0.3-0.35g. Accordingly, the average accelerations calculated by GeoSyntec for Section G-G are considered reasonably conservative, but those for Section F-F should be increased by at least 20 percent.

SHEAR STRENGTHS OF MUNICIPAL WASTE AND LINER INTERFACES

The shear strengths adopted by GeoSyntec for the waste and liner interfaces in the Phase II analyses are all higher than those used two years ago for the Phase I

analyses. Presented below are comparisons between the different strength values in the two sets of GeoSyntec evaluations:

Material/Interface	GeoSyntec Phase I	GeoSyntec Phase II	Adopted for review purposes by DWR
Municipal Waste	C = 100 psf PHI = 28 deg.	C= 900 psf PHI = 31 deg.	C = 500 psf/0 psf PHI = 0 deg./33 deg.
Base Liner	C = 0 psf PHI = 19 deg.	C= 665 psf * ✓ PHI = 15 deg. ✓	C = 665 psf PHI = 15 deg.
Slope Liner	C = 0 psf PHI = 8 deg.	C= 35 psf ✓ PHI = 10 deg.✓	C = 35 psf PHI = 10 deg.

Note: * GeoSyntec actually employed three alternative sets of revised shear strengths for the base liner. The values shown gave the lowest factors of safety for the three alternative strengths.

The use of the higher shear strengths in the Phase II analyses by GeoSyntec results in factors of safety that are generally between 0 and 20 percent higher than those that would have been calculated using the Phase I strengths, depending on the potential sliding surface being analyzed. Also shown above are the shear strengths adopted by DWR in performing review analyses. For the most part, GeoSyntec was able to reasonably justify the higher shear strengths on the basis of laboratory test results. Figures 2 and 3 illustrate the higher strengths justified by the post-peak resistances determined in the laboratory.

DWR does not believe, however, that GeoSyntec was able to justify the significantly higher shear strengths (C=900 psf, PHI = 31 deg.) for waste fill in the Phase II analyses. This is because these strengths are estimated for the waste fill at the Oil landfill, a landfill thought by many to have a higher component of soil in the waste than in many other landfills. Accordingly, we adopted the more common bilinear strength envelope (C=500/0 psf, PHI = 0, 33 deg.) for use in the review analyses. This bilinear strength envelope is derived from the studies by Kavazanjian et al. (1995), and while not as high as what was proposed for the Phase II analyses, it is still higher than that adopted for the Phase I studies (see Figure 4).

SLOPE STABILITY ANALYSES

DWR reviewed the slope stability analyses performed for the Phase II development and performed several independent check analyses using the waste strengths adopted by GeoSyntec and the waste strengths assumed by DWR. Only

the most critical potential sliding surfaces were checked. The results of the DWR check analyses are summarized below:

SECTION	GEOSYNTEC GeoSyntec Waste Strength Program STABL (Spencer's M.)	DWR GeoSyntec Waste Strength Program SLOPEW (Spencer's M.)	DWR DWR Waste Strength Program SLOPEW (Spencer's M.)
SECTION F-F (Southeast)	Static F.S.= 2.32 ** ky = 0.21g **	Static F.S.= 1.88 ky = 0.15g	Static F.S.= 1.83 ky = 0.14g
SECTION G-G (Interim SW)	Static F.S.= 1.79 ky = 0.21g	Static F.S.= 1.64 ky = 0.21g	Static F.S.= 1.44 ky = 0.19g
SECTION G-G (Interim NE)	Static F.S.= 3.02 ky = 0.20g	Static F.S.= 2.50 ky = 0.25g	Static F.S.= 2.38 ky = 0.23g

Note: ** Denotes that the GeoSyntec analysis for Section F-F contained an error in the analysis. After correction, the Static F. S. = 1.87, and ky=0.14g.

The slope stability check analyses performed by DWR using the DWR strengths are summarized in Figures 5 through 10. In general, the DWR analyses showed lower factors of safety and yield accelerations (ky) than did the GeoSyntec analyses. In particular, the results for Section F-F (Southeast) determined by DWR were significantly lower than those determined by GeoSyntec. The reason for this is that an apparent error was found in the GeoSyntec analyses of Section F-F that caused the potential sliding surface to pass through the waste fill rather than through the base liner interface. After correcting the GeoSyntec STABL input file for this error, the analysis by computer program STABL gave the same answer as the DWR analyses using program SLOPEW. Details of these analyses and the error were previously telefaxed to both Ed Kavazanjian of GeoSyntec and you on May 25, 1997. Due to the resource limitations of this review, DWR was not able to determine how many of the GeoSyntec analyses have this type of error, or whether it is limited to only Section F-F.

DISPLACEMENT ANALYSES AND RESULTS

DWR has been using a maximum limit of 6 inches for acceptable earthquake-induced displacements within a base liner system. In the analyses for the Phase II development, GeoSyntec results indicated a minimum yield acceleration of 0.20g. With a yield acceleration of 0.20g, GeoSyntec calculated a maximum earthquake-induced deformation of 5.3 inches. At face value, this would have been reasonably conservative and considered adequate. However, the slope stability check analyses performed by DWR generally resulted in lower yield accelerations. This in turn results in higher earthquake-induced displacements being calculated. Presented below are estimates of the potential earthquake-induced displacements for the three sections analyzed:

Section	kmax (g)	DWR ky (g)	DWR Est. EQ-Induced Displacement (inches)
Section F-F (Southeast)	~0.33***	0.14	10
Section G-G (Interim SW)	0.41	0.19	8
Section G-G (Interim NE)	0.33	0.23	< 2

Note: *** Denotes minimum value for kmax estimated by DWR as discussed in previous section. All other values of kmax obtained from Table 5-5 in the November 11, 1996 report prepared by GeoSyntec.

The results for the most critical sections indicate that both the interim southwest slope of Section G-G and the southeast slope of Section F-F would exceed the 6-inch criterion. For Section G-G, this is probably acceptable because the exceedance is only a small amount and this slope has been identified as an interim slope rather than a permanent slope.

For the southeast slope of Section F-F, however, the 6-inch criterion has been seriously exceeded and this slope has been understood to be a permanent slope. Consequently, additional work and information will be needed to confirm that the

proposed design in this area meets the stability criteria required for landfills. As stated previously, my April 29, 1996 review report to you indicated that the apparent low stability of this slope could probably be resolved by appropriately considering three-dimensional effects. To date this has not been submitted, presumably because GeoSyntec believed that the two-dimensional analyses alone demonstrated adequate stability. However, in light of the error found in their stability calculations for Section F-F, consideration of three-dimensional effects would now seem to be necessary. As suggested in our previous review, DWR believes that the Section F-F slope should have an overall minimum yield acceleration of approximately 0.18g in order to meet the 6-inch criterion.

SUMMARY OF FINDINGS AND CONCLUSIONS

1. The earthquake loading parameters and accelerograms used by GeoSyntec in the Phase II analyses are considered reasonably conservative and adequate.

2. The results of the dynamic response analyses appear to be generally reasonable for most of the sections considered. DWR believes that a minimum kmax of 0.33g should be used in light of the very high seismic loadings at this site and the uncertainties associated with the rapidly changing state-of-practice associated with dynamic response analyses.

3. The shear strengths used by GeoSyntec in the Phase II analyses are generally higher than those used for the GeoSyntec analyses of the Phase I development. With the exception of the shear strength adopted for the waste fill, the higher strengths are based on laboratory test results and are considered reasonable. DWR assumed a somewhat lower shear strength for the waste fill in the stability check analyses performed in this review.

4. The stability check analyses performed by DWR resulted in lower factors of safety and yield accelerations than those determined by GeoSyntec. In particular, the results for Section F-F were found to be significantly lower. The reason for this is an error in the GeoSyntec analyses which causes the potential sliding surface to pass through the waste fill rather than through the base liner. It is not known how many of the GeoSyntec analyses have this type of error.

5. Even with the lower computed factors of safety and yield accelerations, DWR found adequate stability for most of the sections analyzed. The stability of the

southwest slope of Section G-G was found to be marginal, but probably acceptable due to its interim nature. The results for the southeast slope of Section F-F do not meet the earthquake-induced deformation criterion previously established for other landfills.

6. The analyses performed by both GeoSyntec and DWR did not consider three-dimensional stability. It may be that appropriate consideration of three-dimensional slope stability effects may show that the proposed Section F-F would have adequate stability. This was suggested to be done in a previous review, but has not yet been submitted to date.

RECOMMENDATIONS

1. It is recommended that the southeast slope of Section F-F be reanalyzed to consider three-dimensional effects, or be redesigned to meet earthquake-deformation criteria.

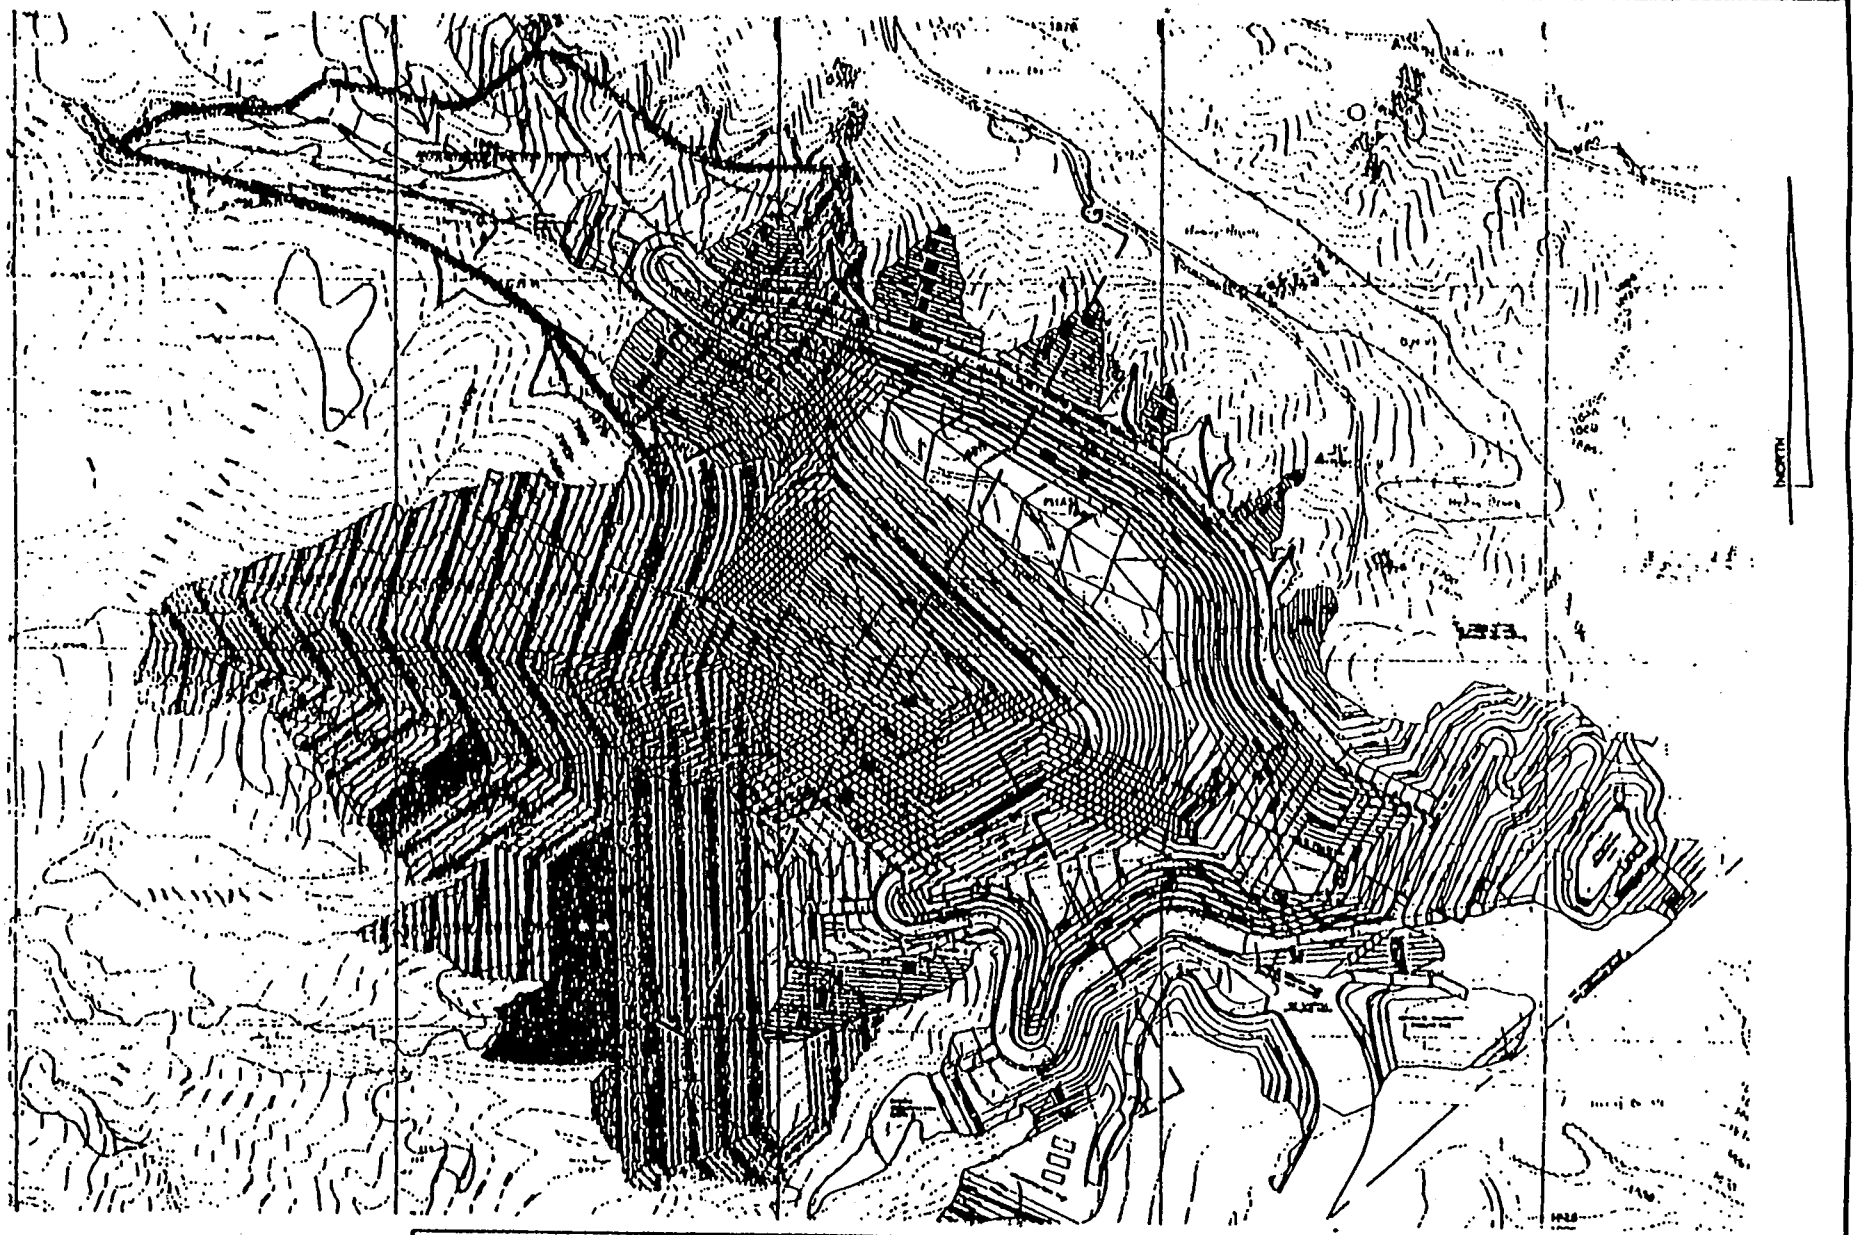
2. It is recommended that the analyses for other sections be checked to verify that the apparent error discovered in Section F-F did not occur in these other analyses.

3. As for all landfill developments, conclusions regarding stability are heavily dependent on the shear strengths assumed. These conclusions are only valid as long as the materials to be used have engineering properties comparable to the values assumed in the analyses. Accordingly, we continue to endorse quality assurance testing during construction of all landfill liner elements and recommend that such testing be carried out during the construction of the Phase II development. We note that the higher strengths adopted for the base and slope liner interfaces were justified on the basis of such testing for the Phase I construction.

FINAL COMMENT

It is beyond the DWR scope of work for DWR staff to either accept or reject applications and/or specific engineering analyses. The purpose of this supplemental review was to determine if the proposed Phase II development would have adequate stability. Unfortunately, it appears that additional effort will be needed to resolve

stability questions on the southeast slope of Section F-F. When additional information is submitted, we would be happy to assist in reviewing the studies.



I hope this provides the review and information you requested. If you have any questions, please call me at (916) 653-3927.

Sincerely,

Leslie F. Harder, Jr., Chief
Division of Engineering

14735-51 San Fernando Road
Sylmar District
D. M. Nos. 7748, 7750 & 7756

Department of Building and Safety

Greetings:

In the matter of the application of North Valley Land Development Corporation for Variance from the provisions of Zone A1-1-O, please be advised that based upon the Finding of Facts hereinafter set forth and by virtue of authority contained in Section 96 of the City Charter and Section 12.27-B, 1 of the Municipal Code, the Associate Zoning Administrator, to whom the matter was assigned, hereby grants a Variance from the provisions of Article 2, Chapter 1 of said Code on an approximate 300-acre site including portions of Lots 9 and 10, Tract No. 10422 and portions of Tract No. 9813, as more particularly described in the application which by reference is made a part hereof, located at 14735-51 San Fernando Road, Sylmar District, but only insofar as such Variance is necessary to permit the continued operation of the existing dump facilities and its expansion for the disposing of rubbish and trash by the cut and cover land fill and reclamation method, upon the following terms and conditions:

1. That all dumping, cut and cover, grading and compaction operations, as well as all activities related to the operation herein authorized on the property, shall be conducted in accordance with the "Minimum Regulations for Dumps in the City of Los Angeles", adopted by the Board of Public Works on August of 1959 and amended on March 22, 1965 and with any subsequent amendments thereto, except as herein specifically permitted, required or modified. Further, said requirements shall have the same effect as if herein stated in detail as conditions of this authorization.

2. That so long as Bradley Avenue is a secondary highway on the City's Master Plan of Highways and traversing the property, there shall be no land fill operations within 80 ft. of either side of the present traveled roadway or natural drainage course along the canyon bottom. If practical difficulties result from the reasonable enforcement of this condition, modification may be made by a Zoning Administrator in keeping with Exhibit "A" attached to the file.

3. That complete plans for all new buildings or structures or any relocation of said buildings or structures, together with a detailed plot plan showing the exterior portions of the property, the location of all proposed buildings or structures, driveways, parking areas, type of surfacing, enclosing fixtures, drainage channels, water mains, fire hydrants, fire breaks or ridges, signs, etc., be submitted to and approved by a Zoning Administrator prior to the issuance of any permits or use of the property for the purposes herein authorized. Further, that prior to the submission of the above-referred to plan or plans to a Zoning Administrator, such shall first be submitted to the Bureau of Engineering, City Fire Department and the Department of Water and Power for consideration and recommendations which shall be noted on said plans or on separate letter.

4. That a Zoning Administrator hereby reserves the right to modify Condition No. III, B. of the Board's Minimum Dump Regulations which states, "all deposited waste material shall be covered as required in "C" by midnight of the day when the waste material is dumped or deposited", to an earlier hour in the event that either additional urbanization takes place within a closer proximity to the operations or this late activity results in a nuisance to the adjoining areas.

5. That no new dumping operations shall be started on the property until a permit has first been secured from the Board of Public Works.

6. That there be no vehicular entrance or exits provided to the property, except from San Fernando Road using essentially the present road entering the property, and that any necessary parking of automobiles, trucks or other motor vehicles be confined to the canyon portion of the premises herein authorized for rubbish disposal purposes. In no event shall parking of any motor vehicles or mechanical equipment used in the operations be permitted on the front

portion of the property where same would be visible to adjacent or surrounding properties or persons using the public ways. Further, that all entrance and exit driveways or roadways and all parking areas be suitably surfaced with a concrete or asphaltic surfacing of adequate thickness to withstand heavy trucking operations and shall be maintained in good condition at all times to prevent dust nuisance.

7. That there shall be no grading, earth moving or dumping operations within the area proposed to be acquired by the State for freeway construction as indicated on Exhibit "B" attached to the file. Further, any such operations within horizontal 50 ft. of such area or any grading operations which might create an unsuitable condition to the proposed State property shall first be submitted to the State Division of Highways for approval prior to the commencement of such operations.

8. That prior to the commencement of any grading or land fill operations less than 50 vertical feet from any existing ridge, plans for the proposed grading, indicating finished elevations, shall be submitted to and approved by a Zoning Administrator. Further, that any fill above any existing ridge elevation shall be face with unmixed natural soil and in no event contain any rubbish of any kind and the finished elevation shall be in keeping with Exhibit "B".

9. That there shall be no dumping in the two canyons draining to the east to San Fernando Road and any filling shall be done only with unmixed natural soil. Further, prior to any filling operations in the area, final plans shall be submitted to the State Division of Highways for comments and recommendations and to a Zoning Administrator for final approval.

10. That this variance shall be valid and in full force and effect for a period of twenty-five (25) years from the effective date hereof and shall be null and void thereafter.

11. That there shall be no dumping operations on the property between sundown of any one day and 6:00 a.m. the following day. This authorization provides that the dump may be operated seven (7) days a week, except dumping privileges shall not be extended on Sunday to licensed rubbish collectors, grading or earth hauling contractors or governmental agencies, but such privileges shall only be extended to the general public. Further, covering and compaction operations shall be held to a minimum on Sundays.

12. That an attendant, properly instructed as to the terms and conditions of this variance, be on duty at all times the property is open for rubbish disposal activities and that at other times the gates leading to the rubbish disposal area of the premises be kept closed and locked so that materials cannot be brought onto any portion of the premises.

13. That the Zoning Administrator reserves the right to impose additional conditions or require corrective measures to be taken, if, in his opinion, or in the opinion of the concerned public agencies, the activities conducted on the property prove to be materially detrimental to the occupants of surrounding property or if such measures or conditions are necessary to protect public health, safety, and general welfare.

14. That at the expiration of this grant or the completion of the land reclamation operations, the premises shall be left in a neat and orderly manner with no uncovered material, debris or waste products left on the premises. Further, upon the completion of the project, the applicant or owners shall advise the City and County Recreation and Parks Department that the property is available for recreational purposes.

15. The variance hereby allowed is conditional upon the privileges being utilized within one hundred-eighty (180) days after the effective date hereof, and if they are not utilized or construction work is not begun within said time, and carried on diligently to completion of at least one usable unit, this authorization shall become void, and any privilege or variance granted hereby shall be deemed to have lapsed, unless a Zoning Administrator has granted an extension of the time limit, after sufficient evidence has been submitted that there was unavoidable delay in taking advantage of the variance. Once any portion of the variance privilege is utilized, the other conditions thereof become immediately operative and must be strictly complied with.

The applicant's attention is called to the fact that this variance is not a permit or license, and that any permits and licenses required by law must be obtained from the proper public agency. Furthermore, that if any condition of this grant is violated, or if the same be not complied with in every respect, then this variance shall be subject to revocation, as provided in Section 12.27 of the Municipal Code. In the event the property is to be sold, leased, rented, or occupied by any person or corporation other than yourself, it is incumbent that you advise them regarding the

conditions of this grant. The Associate Zoning Administrator's determination in this matter will become effective after an elapsed period of ten (10) days from the date of this communication, unless an appeal therefrom is filed with the Board of Zoning Adjustment.

FINDING OF FACTS

After thorough consideration of the statements contained in the application, the report of the Planning Associate thereon, the statements made at the hearing before the Associate Zoning Administrator on October 29, 1965, proceedings in connection with Z. A. Case No. 14544 which authorized 45 acres of the subject property for dumping purposes and Z. A. Case No. 15925 which modified conditions of the previous case to permit the dumping of garbage, as well as B.Z.A. Case No. 1251, all of which are by reference made a part hereof, as well as personal inspection of the subject property and surrounding district, I find that practical difficulties, unnecessary hardships or results inconsistent with the general purpose of the A1-1-O Zone would result from a strict enforcement thereof, and that the four requirements and prerequisites for granting a variance as enumerated in the City Charter and in Section 12.27-D, 1 of the Municipal Code have been established by the following facts:

1. The subject property involves 300 acres of an approximate 500-acre ownership located at the extreme northerly tip of the city, southwesterly of San Fernando Road. The topography of the property and ownership consists of steep hills and canyons, with the principal drainage being into Sunshine Canyon. Approximately 45 acres of this area on the southerly side of the canyon bottom was authorized for similar operations in March of 1958 under Z. A. Case No. 14544. This authorization contained some 22 conditions to provide for the proper orientation of the use within the area and which included several conditions imposed by the Board of Public Works as outlined in its "Minimum Regulations for Dumps in the City of Los Angeles". The canyon in which the existing dump is being operated is almost filled to capacity and to continue the public service being performed by the operators, the subject expansion was requested. As outlined in Z. A. Case No. 14544, this area of Sunshine Canyon was considered acceptable for cut and cover dumping operations in view of its remoteness and isolation from all adjoining and developed areas, except the canyon mouth itself where access is taken to San Fernando Road. The property has been expanded however, to include an area bordering San Fernando Road and the subject property has a frontage along the southwesterly side thereof of approximately 4800 ft. This area contains two relatively large box canyons with the highest point

(Ø3)

B. Z. A. Case No. 1632 September 6, 1966

- 2 -

Section 12.28 of the Municipal Code, sustained the Associate Zoning Administrator's determination on the matter and denied the appeal. The Board did, however, impose additional conditions to read as follows:

2-A - That in no event shall any toe or cut and fill operations of any type be permitted on that portion of the property in question lying within 600 ft. of San Fernando Road as shown on Exhibit "B" attached to Z. A. Case No. 17804 or within that portion of the property considered for acquisition by the California State Division of Highways as shown on Exhibit A-1 attached to the file.

14-A - That in the event the grantee is aggrieved by any determination by any Zoning Administrator in connection with this grant or conditions herein imposed, such matter shall be forthwith appealable to this Board.

All other conditions and requirements under Z. A. Case No. 17804 not in conflict with the above mentioned condition shall remain in full force and effect, except that the date of this communication shall be considered as the effective date of this authorization.

The applicant's attention is called to the fact that this variance is not a permit or license, and that any permits and licenses required by law must be obtained from the proper public agency; that if any condition of this variance is violated or not complied with in every respect, the variance shall be subject to revocation as provided in Section 12.27 of the Municipal Code; and that in the event the property is sold, leased, rented or occupied by any other person or corporation, it is incumbent on the owner to give notice of the conditions of this grant.

Very truly yours,

Roger S. Hutchinson
Chairman

Ralph O. Romero
Ralph O. Romero
Secretary

Branch Office - Valley

EXHIBIT #5

8. The appropriate mechanism to cure the violations relating to the height of the fill and operations beyond the variance application boundaries is to file a new variance over the entire operation, with a closure date identical to the extant variance. In the meantime, any activities which would exacerbate or continue the violations must cease.

To cure the violations of filling less than 50 vertical feet from existing ridges and filling too close to Bradley Avenue and the drainage course, plans for the proposed grading, indicating finished elevations, must be submitted to the Zoning Administrator, under the authority in Condition No. 8 of the grant. Such a submission cannot occur until a final action on the required new variance has been made.

Additional conditions are necessary to address the continuing impacts from dust, and rubbish blowing from the landfill.

While the allegations regarding the health concerns remain unproven, it is desirable to conduct further investigations to settle this aspect.

NEED FOR ADDITIONAL CONDITIONS:

Pursuant to Section 12.27-B,5 of the Municipal Code, the Administrator finds that certain conditions of the variance have not been complied with, and pursuant to Condition No. 13 of extant Case No. ZA 17804, that certain activities on the property have proven to be materially detrimental to the occupants of surrounding property, and that additional conditions are necessary to protect the public health, safety and general welfare.

For the reasons discussed above and expanded further in this report and in order to bring about compliance with the applicable regulations in this case, the landfill shall be subject to the following additional conditions of operation.

ADDITIONAL CONDITIONS

1. That within 60 days of the effective date of this determination, the operator of the landfill shall file a zone variance over the property covered by extant Case No. ZA 17804, and any additional areas necessary to incorporate filling and/or grading which has occurred beyond the original application boundaries. This variance shall be filed with a request for the same expiration date as under extant Case No. ZA 17804. The primary intent of this filing shall be to seek to cure any violations of the original grant which have occurred with respect to elevation of fill (original Condition No. 8 and original Exhibit C), filling and/or grading beyond the original variance boundaries, filling and/or grading in close proximity to Bradley Avenue and the adjacent drainage course (original Condition No. 2), filling and/or grading operations less than 50 vertical feet from any existing ridge (original Condition No. 8), and any other matters deemed appropriate by the Zoning

Administrator. Also, Condition No. 2a under BZA Case No. 1632 (dated September 6, 1966) shall be evaluated as to conformity, requiring that no cut and fill operations occur within 600 feet of San Fernando Road.

2. Prior to a final determination on the refiled zone variance required in Condition No. 1, the operator shall cease immediately all activities which continue or exacerbate violations of ZA Case No. 17804, with the conditions and exhibits attached thereto. This shall include, but not be limited to, any grading and/or filling outside the original application boundaries; any filling and/or grading within less than 50 vertical feet from any existing ridge; any grading and/or filling operations within less than 80 feet of Bradley Avenue and the adjacent water course; and any filling in excess of the elevations indicated on Exhibit C in the ZA 17804 case file. To establish a baseline for this condition, the survey by the Bureau of Engineering dated April 28, 1988 shall be used.

3. Should the newly filed zone variance under Condition No. 1 be approved, within 90 days of the effective date of the determination the operator shall submit to the Office of Zoning Administration plans for the proposed final contours, in conformity with the conditions of the new variance governing boundaries, elevations, distances from features and any other relevant conditions contained therein. Such plans shall accurately identify all areas of finished grade which exist at that time. The Office of Zoning Administration, in consultation with the Office of Council District No. 12 and the Bureau of Sanitation, shall certify the accuracy of the final contour plans prior to approval.

The operator of the landfill shall continue to submit such final contour plans to the Office of Zoning Administration every six months thereafter until the termination date of the grant. Should such plans indicate that the limits of a new approval have been reached at all points, then closure shall occur immediately.

4. Should the newly filed zone variance under Condition No. 1 be denied, closure of the landfill shall occur immediately. The operator of the landfill shall file final contour plans with the Office of Zoning Administration within 90 days of the effective date of such denial. Such plans shall accurately reflect conditions as they exist at that time, including any violations of the extant zone variance 17804, and all areas of finished grade. The Office of Zoning Administration shall certify as in Condition No. 3.

5. That when proposed final contours plans are submitted pursuant to Condition Nos. 3 or 4, a closure plan shall be submitted including, but not limited to, final landscaping; gas flaring and/or distribution; and maintenance and monitoring of physical conditions on the site.

6. That in order to control airborne dust and litter, the following shall be required in addition to any requirements of the Bureau of Sanitation or other regulatory agencies:

   a. Maintain a daily written log, available at all times to authorized personnel of any regulatory agency, which includes notation of time of observation, average wind speed and wind direction as follows: once in the morning before opening the gate for receipt of refuse, once between 11 a.m. and 1 p.m., and once in the late afternoon before closing. The average wind speed determination shall be based upon a minimum 15 minute period of observation.

   b. When refuse is being actively received, operate a minimum of three water trucks to prevent fugitive dust emissions. When refuse is not being actively received, operate a minimum of one truck.

   c. Obtain and maintain a generator of sufficient power and capacity to maintain the water pumping system during power outages.

   d. Spray soil sealant over the inactive landfill areas to control dust emissions. Prior to each day when the landfill will be closed to refuse receipt, apply soil sealant to the previous active cut area that has not already been sealed.

   e. Maintain in good operating condition the water delivery line at the top of the landfill to reduce turnaround time for water tank refill.

   To the extent that the operator has already complied with any of the foregoing conditions, documentation of same shall be supplied to the Zoning Administrator.

7. That within 60 days of the effective date of this determination, the operator shall initiate the following to evaluate the impacts, if any, upon health by the landfill operation: A systematic sampling and analysis of air and soils in the area west of the Golden State/San Diego Freeways, north of Rinaldi Street, east of Reseda Boulevard and to the City limits on the north.

   The study design of such survey shall be submitted to the Los Angeles County Health Department for review and approval prior to implementation, in consultation with the Office of Zoning Administration and the Office of Council District 12. The results of the sampling and analysis shall be submitted to the same agencies and offices.

8. That all of the terms and conditions of extant ZA Case No. 17804 shall remain in effect as if restated herein except for any modifications or amplifications as authorized herein.

9. That should failure to comply with any condition herein be sufficiently documented to the satisfaction of the Office of Zoning Administration, a public hearing shall be scheduled to determine whether the extant variance and authority to operate the site should be repealed or rescinded.

The Zoning Administrator's determination in this matter will become effective after September 16, 1988, unless an appeal therefrom is filed with the Board of Zoning Appeals. Any appeal must be filed on the prescribed forms, accompanied by the required fee and received and receipted at a Public Office of the Department of City Planning on or before the above date or the appeal will not be accepted.

FINDINGS OF FACT

After thorough consideration of the statements and correspondence contained in the file, the statements made at the public hearing before the Zoning Administrator on March 14, 1988, all of which are by reference made a part hereof, as well as personal knowledge of the property and the surrounding district, I find that there is cause for additional conditions to be placed on the property under Section 12.27-B,5 of the Municipal Code and Condition No. 13 of Case No. ZA 17804, as established by the following facts:

I. BACKGROUND

On March 14, 1988, this Office conducted a public hearing to solicit testimony and gather information bearing upon the existence for cause to consider the revocation, modification or discontinuance of the zone variance approval for the existing Sunshine Canyon Landfill. Revocation consideration was sought by Councilman Hal Bernson.

In a letter to Franklin P. Eberhard, Chief Zoning Administrator, dated October 30, 1987, Councilman Bernson stated: "It is my intention and that of the 7,000 residents of the homes next door to the dump not to have any additional approvals or variances from the 1966 conditions. We have reviewed the maps and taken some surveys and believe that the dump is technically full and should be closed. Any further growth of this dump, should be considered in light of their permit requests now pending with the County of Los Angeles, who is reviewing the application for expansion and EIR. To allow further conditions or growth is a violation of the City's intent in the 1966 permit and should only be considered under full public scrutiny with public hearings ordered."

The Chief Zoning Administrator instructed that proceedings be initiated under Section 12.27-B,5 of the Los Angeles Municipal Code and under Condition No. 13 of Case No. ZA 17804 to determine validity for cause to modify or revoke said operation. Hearing notices were mailed on February 4, 1988 to the owner of record of the site, representatives of the owner, representatives of the North Valley Coalition, the Granada Hills Chamber of Commerce and the Granada Hills Homeowners Association. Additional copies were

On November 29, 1988, the Board of Zoning Appeals was to have conducted a public hearing on the above-referenced matter. However, the hearing was rescheduled to December 6, 1988 because the Board was unable to convene a quorum to consider this matter on November 29, 1988.

Accordingly, after thorough consideration of all available records and evidence previously introduced before the Zoning Administrator, his findings and determination and subsequent arguments and comments, the Board of Zoning Appeals, after conducting a public hearing, found that the Zoning Administrator did not err or abuse his discretion in his determination and denied the appeals, subject to modification of the conditions imposed in the determination as follows:

Condition No. 2 (modified)

That, prior to a final determination on the refiled zone variance required in Condition No. 1 of the Zoning Administrator's determination, dated September 1, 1988, the operator shall cease immediately all activities that continue or exacerbate violations of ZA Case No. 17804, with the conditions and exhibits attached thereto. This shall include, but not be limited to, any grading and/or filling outside the original application boundaries; any filling and/or grading within less than 50 vertical feet from any existing ridge; any grading and/or filling operations within less than 80 feet of Bradley Avenue and the adjacent water course and any filling in excess of the elevations indicated on Exhibit C in the file of ZA 17804.

Condition No. 4 (modified)

That, should the newly filed zone variance under Condition No. 1 of the determination of the Zoning Administrator, dated September 1, 1988, be denied, closure of the landfill shall occur immediately. The operator of the landfill shall then file final contour plans with the Office of Zoning Administration within 90 days of the effective date of such denial. Such plans shall accurately reflect conditions as they exist at that time, including any violations of the extant zone variance under ZA 17804, and all areas of finished grade, based on a current baseline survey. The Office of Zoning Administration shall certify as in Condition No. 3 of determination, dated September 1, 1988.

Condition No. 6 (modified)

That, in order to control airborne dust and litter, the following shall be required in addition to any requirements of the Bureau of Sanitation or other regulatory agencies.

a. That the operator of the landfill shall install and maintain, in good operating condition, an anemometer at an exposed location on the landfill, as approved by the Executive Officer of the South Coast Air Quality Management District. Further, that in the event of a breakdown in the operation of the anemometer, the District shall be notified within 24 hours, and repairs shall be undertaken promptly.

b. That the operator of the landfill shall maintain a written log, available at all times to inspectors of the South Coast Air Quality Management District, which includes notation of time of observation, wind speed and wind direction (read and recorded three times per day) as follows:

1) once in the morning before opening the gate for receipt of refuse (or before 10:00 a.m. when there is no receipt or refuse);

2) once between 11:00 and 1:00 p.m. and

3) once in the late afternoon before closing (or after 3:00 p.m. when there is no receipt of refuse).

c. That water trucks shall be operated during daylight hours to prevent dust emissions in violation of South Coast Air Quality Management District Rules and Regulations and California Health and Safety Code Section 41700; it shall not be necessary to operate said water trucks on rainy days. A minimum three water trucks shall operate on the landfill unless such trucks are broken down or are in need of repair. The South Coast Air Quality Management District shall be notified within 24 hours of such breakdowns or need for repair. When there is no receipt of refuse, a minimum of one water truck shall be operated throughout the landfill. "Operate" shall mean that normal rest and lunch breaks shall be observed and refueling and other normal vehicle maintenance will occur.

d. That the landfill operator shall ~~investigate~~ seek (mod. June 2089) acquisition of a generator of sufficient power capacity to maintain a water pumping system during power outages.

e. That the landfill operator shall maintain in good operating condition the water delivery line at the top of the landfill to reduce turnaround time for water truck refill.

f. That the landfill operator shall cover all exposed refuse at the working faces by the end of each day.

g. That the landfill operator shall spray encapsulate material (soil sealant) over the inactive landfill areas to control dust emissions. Further, that prior to each day when the landfill will be closed to refuse receipt, soil sealant shall be applied to the previous active cut area that has not already been sealed. To the extent that the operator has already complied with any of the foregoing conditions, documentation shall be supplied to the Zoning Administrator (mod. June 2089)

Condition No. 10 (added)

That, effective immediately, no additional deposition of refuse shall take place in the easterly portion of the southern fill area northerly of the berm; and after December 31, 1989, all refuse deposition shall cease in the entire southern fill area, as such area is depicted on Exhibit C, attached to the file of ZA 17804. Further, that after December 31, 1989, a final contour plan, consistent with the requirements of Condition No. 5 of the Zoning Administrator's determination, dated September 1, 1988, shall be prepared and implemented.

Condition No. 11 (added)

That landfill activity shall be permitted in the northern fill area, as depicted on Exhibit C, attached to the file of ZA 17804, until termination of the grant on September 21, 1991, or until the elevations depicted on Exhibit C, have been reached, whichever shall occur first.

SUMMARY OF PUBLIC HEARING

The Board first considered testimony in support of BZA Case No. 3877, the appeal filed by the operator of the landfill, which contends that the entire decision of the Zoning Administrator was in error and constituted an abuse of discretion in finding that there were violations of existing conditions and detrimental effects on surrounding property. The Board then considered BZA Case No. 3878, the appeal of some neighboring residents, who urged the Board to overturn Finding No. 6 of the Zoning Administrator, revoke the existing variance and close the site immediately.

Testimony in Support of BZA Case No. 3877

The operator's attorney, the manager of the landfill site, a consulting engineer and a consulting surveyor appeared at the public hearing and provided the principal testimony in support of the appeal of BZA Case No. 3877. Additional testimony concerning limited aspects of the case was provided by experts in air quality regulations, revegetation and survey research. Their verbal testimony was supported by the attorney's brief, dated November 30, 1988, and technical reports issued by Purcell, Rhoades and Associates on November 28, 1988, and by James Dorsey and Associates and Handelman-Katherman and Associates on November 30, 1988. These technical reports detailed inconsistencies and inaccuracies in early surveys.

The landfill was described as a well-run and thoroughly regulated component of an increasingly constrained solid waste disposal system. The manager of the site stated that the landfill served an area with a population of approximately 3 million and maintained contracts with the City of Los Angeles and numerous other municipalities for rubbish disposal, as well as being open to the general public. It was observed that the importance of the site had increased dramatically, in large part because of the closure of several local landfills in recent years, as exemplified by the dramatic increase in disposal from 3,000 tons per day in 1982 to 7,000 to 10,000 tons per day at the present and the concurrent increase of on-site employees from 25 to 45. To underscore the importance of keeping the site in operation, numerous nearly identical letters of support for the appeal were received from users, including the City of Santa Monica, waste haulers and construction companies, as well as local residents and business operators, civic and fraternal organizations and the County Department of Health.

1C

The Board considered requests by Antonio Cosby-Rossman, attorney for protestants, dated April 12, 1989, and by Linda J. Bozung, attorney for applicant, dated April 21, 1989, for clarification of the Board's determination, dated April 6, 1989. In addition, the Board considered comments by the Zoning Administrator relating to requested clarifications.

After consideration of these requests, the Board clarified its report as follows:

Condition No. 1 (modified)

That within 60 days of the effective date of this determination, the operator of the landfill shall file a zone variance and separate plan approval over the property covered by extant Case No. ZA 17804, and any additional areas necessary to incorporate filling and/or grading which has occurred beyond the original application boundaries. The variance and plan approval request shall be filed with the same termination date as under extant Case No. ZA 17804. The primary intent of the variance request shall be to seek to cure any violations of the original grant which have occurred with respect to elevation to fill (original Condition No. 8 and original Exhibit C), filling and/or grading beyond the original variance boundaries, filling and/or grading operations less than 50 vertical feet from any existing ridge (original Condition No. 8), and any other matters deemed appropriate by the Zoning Administrator. Also, Condition No. 2a under BZA Case No. 1632 (dated September 6, 1966) shall be evaluated as to conformity, requiring that no cut and fill operations occur within 600 feet of San Fernando Road. The plan approval request shall be filed to seek to cure violations with respect to filling and/or grading in close proximity to Bradley Avenue and the adjacent drainage course.

2. Page 3, Condition No. 6d, line 1 - change "investigate" to "seek"

3. Page 3, after Condition 6g - add

"To the extent that the operator has already complied with any of the foregoing conditions, documentation shall be supplied to the Zoning Administrator."

4. Page 8, paragraph 2, 4th sentence - delete.

5. Page 9, paragraph 4, line 9 - change "27" to "24"

6. Page 10, carry-over paragraph, line 2 - change 1,727 to 1,724

These changes shall serve to clarify the Board's intent in this matter; they shall become effective upon the issuance of this letter.

C.D. 12
Legal Description:
Portions of Lots 9 and 10 of Tract No. 10422 and portions of Tract No. 9613

SUNSHINE CANYON LANDFILL - ZONING ADMINISTRATOR FINDING FOR TIME EXTENSION TO JANUARY 31, 1990

On July 19, 1989, the City Council imposed additional conditions on the operation of the Sunshine Canyon Landfill, under Case No. ZA 17804(ZV). Condition No. 11 therein states:

> "That landfill activity shall be permitted in the northern fill area, as depicted on Exhibit C, attached to the file of ZA 17804, until termination of the grant on September 21, 1991, or until the elevations depicted on Exhibit C, have been reached, whichever shall occur first."

Condition No. 10 therein states in part:

> "That after December 31, 1989, all refuse deposition shall cease in the entire southern fill area, as such area is depicted on Exhibit C, attached to the file of ZA 17804. ... However, if the landfill operator ... by December 31, 1989, has been unable to obtain the required approvals and complete the site preparation necessary to allow landfill activity in the northern fill area, in general conformity with the modified plot plan on file with the City as filed in June 1989 subject to the approval of the Zoning Administrator consistent with Condition No. 11 hereof, refuse deposition shall be allowed to continue in the southern fill area on a month-by-month extension, but only if prior to each month's extension the Zoning Administrator finds that the operator to date

AN EQUAL EMPLOYMENT OPPORTUNITY - AFFIRMATIVE ACTION EMPLOYER

> has in good faith pursued the necessary approvals and site preparation and otherwise is in compliance with the existing variance except as otherwise found to exist; and further provided that no such extensions shall be granted for deposition beyond June 30, 1990."

Documentation submitted by representatives of Browning-Ferris Industries ("Plot Plan Meeting/Contacts Log") indicates pursuit in good faith of the approvals necessary for the northern fill area. The plot plan was filed with the Zoning Administrator on June 15, 1989 and was approved on October 10, 1989. Part of that time period involved 1) withdrawal of an appeal by BFI on an earlier Zoning Administrator action to clear the way for the instant action and 2) the noticing and conduct of a public hearing. On November 6, 1989, the North Valley Coalition appealed the plot plan approval. It is unlikely that a final decision will be issued on the appeal before the end of December. Further, additional City approvals must be acquired and it is unlikely that construction of the project will begin until well after the end of this year.

The Bureau of Sanitation, the lead enforcement agency for Sunshine Canyon Landfill, has indicated that the operation is in compliance with the existing variance, except as otherwise found to exist previously by the City Council.

I therefore find that the operator to date has in good faith pursued the necessary approvals and site preparation and otherwise is in compliance with the existing variance except as otherwise found to exist, and recommend that the City Council allow refuse deposition to continue in the southern fill area until January 31, 1990.

CURATIVE VARIANCE AND CONDITIONS

(Condition 1 of BZA#3877 & 78 orders variance hearing)

2A

CONDITIONS OF APPROVAL

The conditions and requirements of Zoning Administration Case No. 89-1129-ZV have not been modified substantially, except as indicated below.

1. Survey (modified).

   a. The applicant shall prepare a survey of the boundaries and elevations of the approved variance, in conformity with Condition Nos. 2 and 3 herein. Said survey shall be conducted by an independent surveyor mutually acceptable to the applicant and the Office of Zoning Administration, which latter shall act in consultation with the Office of Council District 12, the Bureau of Sanitation and the Bureau of Engineering. Until such survey is completed and certified to the satisfaction of the aforementioned parties, the Bureau of Sanitation shall continue to enforce the boundaries and elevations which have been so utilized since the City Council action of July, 1989.

   b. (Added). Said independent surveyor shall be selected by the applicant within two weeks of the effective date of the subject variance action.

   c. (Added). Said survey shall be provided to the aforementioned City parties for review within ten weeks following the effective date of the subject variance action.

2. Boundary (modified). The herein approved boundaries of the variance shall not exceed the following, whichever incorporates a more extensive area: the extent of any landfill-related activities of any type as they existed at the time of the City Council action of July, 1989, including the "earthwork operations," and the previously established variance boundary line under ZA Case No. 17804.

3. Elevations. The elevations of landfill activities, including those less than 50 vertical feet from any existing ridge, shall not exceed those in existence within the southern fill area as they existed as of June 30, 1990, except as is necessary for purposes of additional cover; nor shall elevations exceed those within the northern fill area as depicted on Exhibit "C" of extant Case No. ZA 17804.

4. Activities (modified). No refuse deposition, no landfilling activities, grading, building or road construction shall be permitted under this action, other than in the northern fill area, pursuant to limitations imposed by Exhibit C of ZA 17804 and subject to the conditions of the approval of plans by the Board of Referred Powers on August 3, 1990.

   Exception (added). Covering of existing landfill with dirt is permitted only if said covering is required in writing by the State of California. Before such covering operation is initiated, said written requirement, including specifications for the covering operation, must be provided to the satisfaction of the Zoning Administrator for placement in the subject BZA 4336 case file.

B.Z.A. CASE NOS. 4336 and 4337 EXHIBIT NO. B-1

5. Oak trees. No oak trees shall be removed from within the area of the variance, except within the northern fill area. Oak trees within that area shall be counted prior to displacement, and replaced at a ratio of two trees for every one removed in strict compliance with the Oak Tree regulations of Section 17.05-R of the Los Angeles Municipal Code.

6. Contours. Within 90 days of the effective date of this determination, the operator shall submit to the Office of Zoning Administration plans for the proposed final contours, in conformity with the conditions of this variance and all other governing extant actions. Such plans shall accurately identify all areas of finished grade which exist at that time. The Office of Zoning Administration, in consultation with the Office of Council. District 12 and the Bureau of Sanitation, shall certify the accuracy of the final contour plans prior to approval. The operator of the landfill shall continue to submit such final contour plans to the Office of Zoning Administration every three months thereafter until the termination date of the grant. Should such plans indicate that the limits of the new approval have been reached at all points, then closure shall occur immediately.

7. Sedimentation basin (modified). Should the applicant proceed with construction of the sedimentation basin, said basin shall be constructed at a size which is adequate to the needs of the existing site, but which is not larger than necessary for the purpose of closure of the existing landfill. The construction shall be designed to meet minimum regulations, and the determination of the final need and size shall be made by the Zoning Administrator in consultation with the appropriate regulatory agencies.

8. Closure (modified).

   a. Within six months after the landfill is full or after September 21, 1991, whichever occurs first, all landfill buildings, scales, checking stations, recycling center and facilities to accept trash shall be dismantled and removed from the site, except for offices and facilities necessary to monitor the closure plans.

   b. (Added). Prior to establishment or continuance of said facilities after September 21, 1991, a plan(s) shall be submitted to the Zoning Administrator along with evidence that said facilities are strictly for the purpose of monitoring the closure plans for the City landfill portion of the site. The Zoning Administrator shall consult with the various regulatory agencies to verify that the facilities are for said purpose before authorizing the continuance or establishment of said facilities. Further, the Zoning Administrator may condition the authorization of said facilities.

9. Compliance with prior cases. All of the terms and conditions of extant ZA Case ZV 78-463 and No. 17804, including the revocation consideration. action of July, 1989, and all granted approvals of plans shall remain in effect as if restated herein except for any modifications or amplifications as authorized herein.

10. Plan approval procedure. The applicant shall be permitted to file an approval of plans under this action to modify the terms and conditions of this grant, and any prior grant governing the variance area, for the

subject to the following terms and conditions:

1. That the use and development of the property shall be in substantial conformance with the plan submitted with the application and marked Exhibit "A" dated December 20, 1989, except as modified herein.

2. That the sedimentation basin shall be constructed at a size specifically designed to meet the needs of the instant authorization, including capturing, containing and reducing the velocity of water from the stream watershed. The determination of such need and size will be made by the Regional Water Quality Board and any other agencies having permit authority with respect to hydrology.

3. That within six months after the landfill is full or after September 21, 1991, whichever occurs first, all landfill offices, checking stations and other buildings shall be dismantled and removed from the site.

4. That oak trees within the northern area shall be counted prior to displacement, and replaced at a ratio of two trees for every one removed.

5. That any fill permitted under this authorization shall be not closer than 600 feet to San Fernando Road, pursuant to BZA Case 1632, and 50 horizontal feet from State property, pursuant to Condition No. 7 under ZA 17804.

6. That the applicant shall conform with all conditions imposed by the Department of Building and Safety with respect to grading, seismic safety and mitigation of construction noise, including but not limited to sound restricted construction equipment and compliance with the applicable provisions of Noise Ordinance No. 144,331.

7. That entry area and access road plans shall be submitted to the City Department of Transportation for approval prior to the issuance of building permits.

8. That prior to the issuance of building permits, the applicant shall obtain a letter from the Fire Department indicating that fire protection measures on the site are to its satisfaction.

9. That, pursuant to Section 6-C,2(b) of the Flood Hazard Specific Plan, the applicant shall submit the instant plans to the Director of Sanitation for assurance of compliance with the provisions of said specific plan.

10. That all other use, height and area regulations of the Municipal Code be strictly complied with in the development and use of the property, except as such regulations are herein specifically varied or required.

11. That the authorized use shall be conducted at all times with due regard for the character of the surrounding district, and the right is reserved to the Zoning Administrator to impose additional corrective conditions, if, in his opinion, such conditions are proven necessary for the protection of persons in the neighborhood or occupants of adjacent property.

The applicant is advised that the above approval of plans is from a zoning standpoint only. Any necessary permits or certificate of occupancy must be obtained from the proper City departments, and the applicant must comply with all other public regulations.

The authorization hereby allowed is conditional upon the privileges' being utilized (i.e., in the case of a use variance, the use approved being lawfully conducted on the site) within one year after the effective date hereof, and if they are not utilized or construction work (i.e., actual substantial physical improvements installed) is not begun within said time and carried on diligently to completion, this authorization shall become void and any privilege or authorization granted hereby shall be deemed to have lapsed unless a Zoning Administrator has granted an extension of the time limit (the request for the extension having been submitted prior to the expiration of the grant and accompanied by the appropriate fee) after sufficient evidence has been submitted indicating that there was unavoidable delay in taking advantage of the authorization. Once any portion of the variance privilege is utilized, the other conditions thereof become immediately operative and must be strictly observed.

The Zoning Administrator's determination in this matter will become effective after April 27, 1990, unless an appeal therefrom is filed with the Board of Zoning Appeals. Any appeal must be filed on the prescribed forms, accompanied by the required fee and received and receipted at a Public Office of the Department of City Planning on or before the above date or the appeal will not be accepted.

FINDINGS OF FACT

After thorough consideration of the statements contained in the application, the statements made at the public hearing before the Zoning Administrator on September 25, 1989, all of which are by reference made a part hereof, as well as personal knowledge of the property and the surrounding district, I find as follows:

1. The original action in the instant case was issued by the Zoning Administrator on October 10, 1989. That action was appealed to the Board of Referred Powers, which considered the matter on January 3, 1990 and January 12, 1990. On the advice of the City Attorney that several procedural requirements of CEQA had not been followed, including a requirement for a 30-day comment period when an action involves State agencies, the Board remanded the matter to the Zoning Administrator pursuant to LAMC Section 12.28-A,7(b). The earliest feasible date for republication of the Mitigated Negative Declaration was January 25, 1990 and the 30-day comment period ended on February 23, 1990. Comments received and the City's

Board of Zoning Appeals
Attn: Anne V. Howell
City Planner
Room 504, City Hall

Dear Ms. Howell:

The Board of Zoning Appeals transmitted an appeal by Wayde Hunter, aggrieved party, from the entire decision and environmental clearance relative to the Zoning Administrator's conditional approval of plans to permit (1) raising in elevation of existing private access road and modification of proximity of northern fill area thereto, pursuant to Exhibit A of ZA Case No. 17804; (2) enclosure of existing watercourse in an underdrain drainage system and installation of a sedimentation basin; (3) relocation of entrance control stations and landfill offices; and (4) installation of a leachate control and treatment system, within existing Sunshine Canyon Landfill site in the A1-1-0 Zone located at 14747 San Fernando Road.

A similar appeal was heard previously on January 3 and 12, 1990, by the Board of Referred Powers under BRP Case No. 1046 (BZA No. 4148). Following a brief discussion with William Waterhouse, Deputy City Attorney, regarding a Negative Declaration for the subject property involving the Sunshine Canyon Landfill site, the Board continued the matter and instructed that the matter be remanded to the Zoning Administrator for further determination pursuant to Section 12.28A7(b of the L.A.M.C.

This is to certify that at a special meeting of the Board of Referred Powers held on August 3, 1990, said Board acting instead of the Board of Zoning Appeals (BZA New File No. 4221), following a public hearing granted the subject appeal in-part. The Board of Referred Powers overruled the Zoning Administrator's action of April 12, 1990 by denying that portion of the request to raise the elevation of an existing water course in an underdrain drainage system and approved plans for the Sunshine Canyon Landfill site to allow the:

EXECUTIVE SUMMARY

Deformation. The January 17 1994, M=6.7, Northridge earthquake permanently deformed the ground surface in the Los Angeles urban region, increasing the elevation of the ground by as much as 20 inches (50 cm), and changing horizontal positions by up to 8 inches (20 cm). The network of geodetic monuments used by engineers and surveyors was thus distorted and rendered inaccurate. The monuments are used for construction and monitoring of the urban infrastructure, including dams, levees, aqueducts, and storm drains; bridges, buildings, and heavy machinery; road and rail transportation routes, communication conduits and pipelines; and property boundaries. We resurveyed the height of 979 leveling bench marks (BMs) and the positions and heights of 66 Global Positioning System (GPS) monuments; emplaced 252 new BMs where the previous monuments were lost or unrecoverable, and added 128 new GPS monuments along critical highways for rapid damage assessment to the main traffic arteries after future earthquakes. In total, 496 monuments were added to the national network. All surveyed monuments are shown on the map; new coordinates and heights are given in the appendix.

Shaking. The Northridge earthquake also strongly shook the ground, with peak shaking exceeding the acceleration of gravity (>1 *g*), and with peak ground velocities of 65 inches per second (or 165 cm/sec). Such sustained shaking and high ground velocities damaged structures and caused surface cracking, liquefaction, ground slumping, settlement, and landslides, which further contributed to damage. Because half of the BMs are located on engineered structures, their displacement not only records the permanent change in height caused by the earthquake to the geodetic network, but also any disturbance of the structures caused directly or indirectly by shaking. We developed a geophysical model of the permanent ground deformation that is consistent with the movement of the geodetic monuments. All BMs with vertical displacements that differ from this model by more than 1.2 inches (3 cm) are considered to be anomalous. The 40 such anomalous or disturbed BMs are shown in the map and listed in the report. Those in engineered structures include railroad and highway bridge abutments and spans, tower and building foundations, catch basins, retaining walls, and culverts; the remainder are typically in engineered fill. The anomalous BMs are identified on the map; driving directions and preliminary site inspections to each anomalous BM are included.

Recommendations. Structures associated with anomalous BMs may be in a weakened state, making them vulnerable to shaking during future earthquakes. Because few structures have been assessed for earthquake effects except by visual inspection, subtle or hidden damage suggested by the settlement or uplift of the structures merits re-inspection. We further suggest that more geodetic monuments be placed on critical transportation arteries, structures, and lifelines, to ensure faster and more accurate post-earthquake damage assessments in the future.

This report includes an analysis, a CD-ROM containing the data files in several GIS (Geographic Information System) and illustration formats, a large-scale color map, and an appendix giving driving instructions to the sites of anomalous bench marks. All files are accessible on a World Wide Web, http//www-socal.wr.usgs.gov/fema .

INTRODUCTION

We seek to restore the integrity of the geodetic network in the San Fernando, Simi, Santa Clarita Valleys and in the northern Los Angeles Basin by remeasurement of the network and identification of BMs which experienced non-tectonic displacements associated with the Northridge earthquake. We then use the observed displacement of BMs in the network to portray or predict the permanent vertical and horizontal deformation associated with the 1994 Northridge earthquake throughout the area, including sites where we lack geodetic measurements. To accomplish this, we find the fault geometry and earthquake slip that are most compatible with the geodetic and independent seismic observations of the earthquake. We then use that fault model to predict the deformation everywhere at the earth's surface, both at locations where geodetic observations exist and also where they are absent.

We compare displacements predicted for a large number of numerical models of the earthquake faulting to the coseismic displacements, treating the earthquake fault as a cut or discontinuity embedded in a stiff elastic solid. This comparison is made after non-tectonic deformation has been removed from the measured elevation changes. The fault slip produces strain in the medium and deforms the ground surface. The model compatible with seismic observations that best fits the geodetic data within their uncertainties is selected. The acceptable model fault bisects the mainshock focus, and the earthquake size , magnitude, is compatible with the earthquake size measured seismically. Our fault model was used to identify geodetic monuments on engineered structures that were anomalously displaced by the earthquake (Figure 1).

1. LEVELING ANALYSIS

1.1 Overview

Leveling measures the height difference between two points along a horizontal line of sight. Summing the relative height differences along a leveling line yields the elevation of those BMs with respect to the height of the first BM. Repeated measurements of height enables measurement of deformation of the Earth's surface with time. Such deformation can occur gradually, such as by land subsidence due to groundwater or oil withdrawal, or by sudden geologic events such as earthquakes. The vertical deformation caused by an earthquake is calculated by subtracting the elevation of points measured before the earthquake from the elevation of the point measured after the event.

Table 1. Preseismic and postseismic leveling surveys analyzed in this study.

POSTSEISMIC DATA				
Line	Order	Date (m/yr)	α	Survey Name

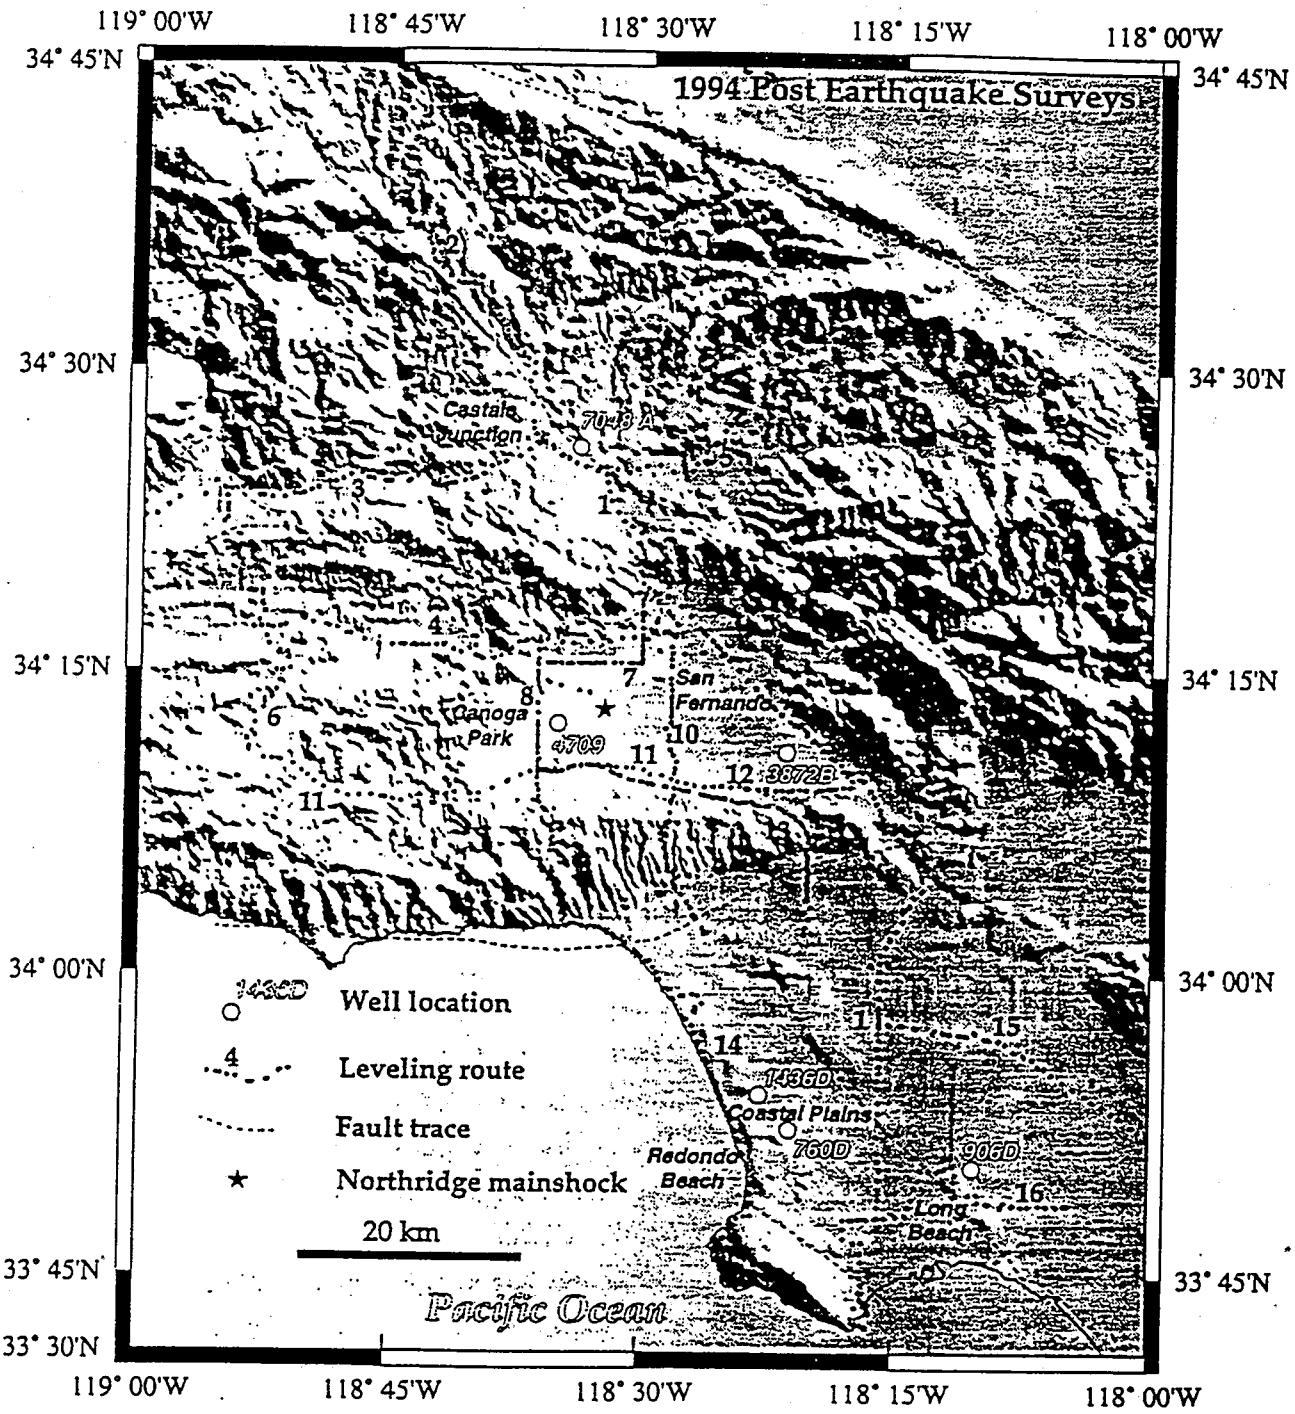

Figure 2. Leveling routes measured as part of this study by the National Geodetic Survey in the San Fernando Valley, Simi Valley and Los Angeles (Survey L24568 parts 1 to 16). Benchmarks are shown as small black dots and each route is labeled 1 to 16 corresponding to Table 1.

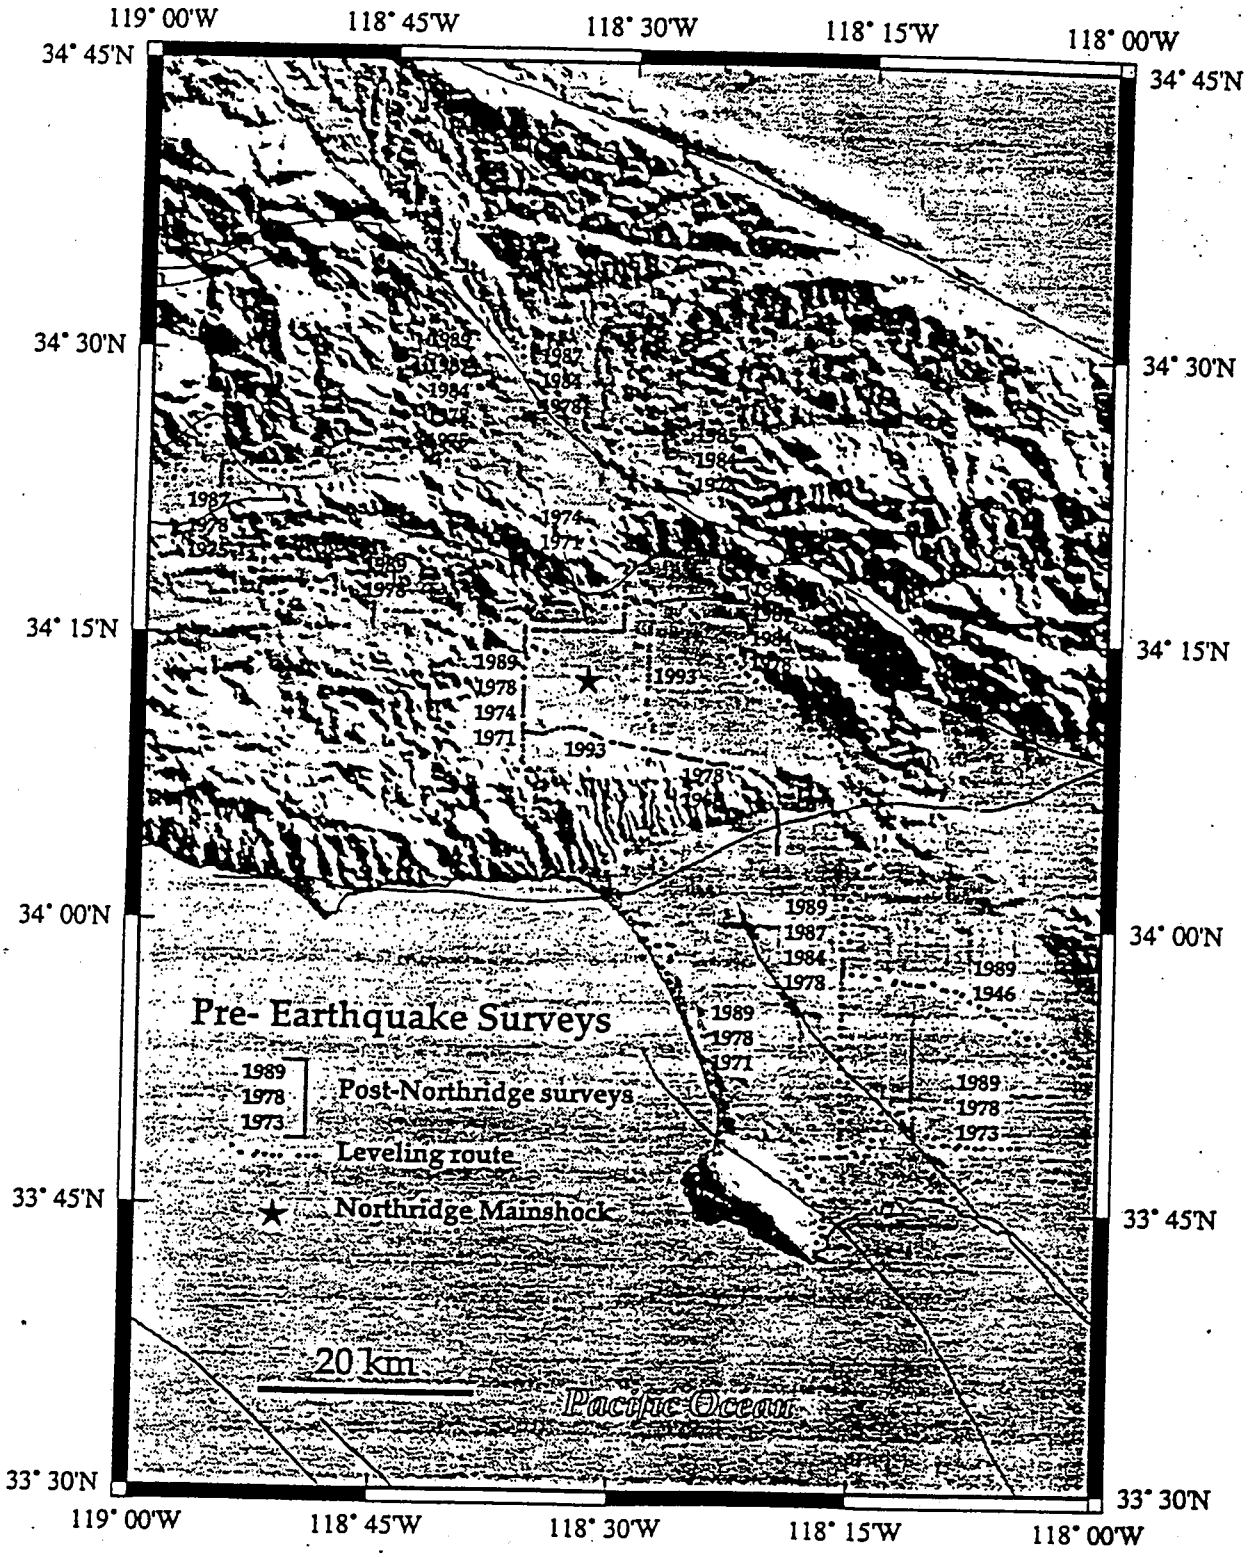

Figure 3. The coseismic leveling data set. Each route is annotated with the years of surveys used to study the possibility of subsidence.

While the earthquake deformation signal is ideally calculated by subtracting surveys made immediately before and immediately after the earthquake, this is rarely possible in practice, and thus non-tectonic effects must be quantified and removed. In the Los Angeles basin, ground subsidence caused by groundwater, natural gas, and oil withdrawal is a continuing source of surface deformation that must be removed from the earthquake elevation changes. We determine the rate of non-earthquake effects by comparing at least three surveys of the leveling route made at different times before the earthquake.

After the Northridge earthquake, between June and August 1994 the National Geodetic Survey, as part of this study, conducted high-precision leveling surveys along 16 leveling routes in the Los Angeles area (Table 1 and Figure 2). To infer the vertical deformation associated with the 1994 Northridge earthquake, surveys of the routes made between 1971 and 1989 were subtracted from the 1994 measurements. The 1994 leveling surveys are referred to as the postseismic data set and the surveys made before the Northridge earthquake referred to as the preseismic data set (Figure 3). Elevations measured at BMs in both pre- and postseismic surveys form the basis of the coseismic data set .

1.2 Non-tectonic deformation: Subsidence

1.2.1 Causes of subsidence in Los Angeles County

A major cause of land subsidence is the withdrawal of groundwater from compressible sediments. As water is withdrawn and the water table lowered, the effective pressure in the drained sediments is increased. Compressible layers then compact under the over-pressure burden that is no longer compensated by hydrostatic pressure. The resulting land subsidence is most pronounced in uncompacted sediments Throughout Southern California oil and gas extraction is also a cause of subsidence. In particular, the Torrance oil field extends from Redondo Beach in the northwest to Long Beach in the southeast. Subsidence at a rate of ~3 cm/yr at Redondo Beach has been attributed to petroleum extraction.

Several criteria were applied in this study to define subsidence features. Subsidence was identified where the elevation decreased between two or more pre-earthquake surveys more than the allowable random survey error. The subsidence feature had to occur over several BMs and, a consistent temporal and spatial pattern of deformation had to exist between the surveys. Subsidence rates were calculated relative to a BM which was adjacent to the subsidence feature and in incompressible rock. This stable BM thus formed a local base level. Dividing the amount of

subsidence below the base level by the time interval yields the subsidence rate. Since subsidence is a dynamic process and its magnitude and extent is affected by water use, rainfall and urban development, the derived rates reflect the average trend of subsidence in the area. Where possible more than two surveys of the route were examined to ensure the trend was not a short term effect.

1.2.2 Water fluctuations in Los Angeles County

Most of the run-off from the San Gabriel and Santa Susana Mountains flows through the San Fernando Valley. The entire Valley is drained by the Los Angeles River system. Since the 1940s, water flow has been controlled by the Hansen and Sepulveda Flood Control basins. Unconsolidated deposits, between 1.5 million and 10,000 years old, underlie the valley floor and are the main water bearing units of the San Fernando Valley. The Saugus Formation, around the northern margin of the Valley and south side of the Santa Susana Range, is composed of continental and marine sediments which also contain water-bearing units. Consolidated rock units in the surrounding mountains define the boundary between water bearing and non-water bearing units. Groundwater is drawn from the unconsolidated sediment aquifer systems that underlie the San Fernando Valley, Los Angeles and Long Beach areas. The main demands for water arise from industrial and urban residential usage.

Water levels in the San Fernando Valley and Los Angeles area have been recorded since the early 1900's. Fluctuations in water levels are influenced by periods of drought and increases in water usage. In the Castaic junction area the depth to water decreased 15 m during 1969 (Well 7048 [*DPW*, 1992]), (Figure 2). From 1969 to 1984 water levels rose another 4.5 m. The period 1984 to 1991, however, saw the water-level drop to the 1969 level. A monitoring well in Canoga Park, west of Balboa Boulevard, has shown little fluctuation in water-level between 1960 and 1991. The general trend at the Canoga Park well, though, has been one of water-level decline (Well 4709, [*DPW*, 1992]). Over a 31-year period the depth to water has increased by 3 m (Figure 4). A second well in the San Fernando Valley (Well 3872B, North Hollywood) has shown much greater fluctuations. The depth to water below the ground surface increased by 24 to 57 m between 1944 and 1967 [*Watermaster*, 1981]. Between 1967 and 1984, however, water levels rose to almost that of the 1940's level (Well 3872B, Figure 2)[*DPW*, 1992]. Water-levels in the well then dropped again by 6 m between 1987 and 1991. In the coastal plains, ground-water fluctuations vary greatly between localities. Two wells, 706C and 1346D, separated by 5 km (Figure 2), indicate the depth to the water-table has decreased. Water-levels have steadily risen by 12 m at well 706C since 1964.

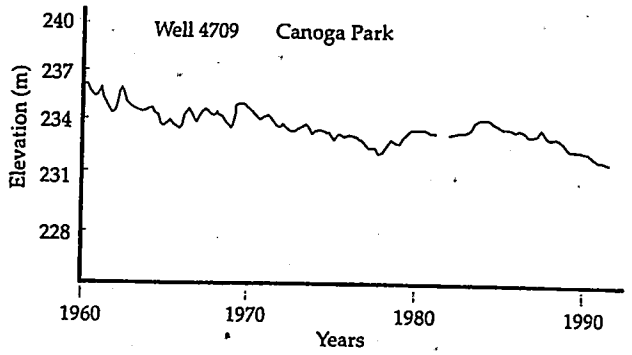

Figure 4 Water level fluctuations at Well 4709 in Canoga Park, *Watermaster* [1981].

At well 1346D the 1964 and 1991 water-levels are about the same [*DPW*, 1992]. Fluctuations over the 27-year period at well 1346D, however, have been large, rising 12 m above the 1964 level by 1976 and then dropping almost 15 m by 1978. In the Long Beach area, water levels remained constant between 1965 and 1974 (Well 906). Between 1975 and 1977 water levels dropped by an average of 9 m and remained at that level until 1982, when water levels began to increase again. Since 1985 the water levels have been close to the 1965-74 level.

1.2.3 Subsidence in the San Fernando Valley and the Los Angeles Area

Subsidence was examined along each of the following leveling routes. The route numbers and names below are keyed to Figure 2 and the National Geodetic Survey line L25468 part numbers. The deduced subsidence rates are summarized as a contoured map in Figure 5. Where the data is insufficient to identify subsidence the contours are dashed e.g., in the San Gabrielle Mountains or the Santa Susana Range.

(1) Castaic via San Fernando and Los Angeles to San Pedro .
Subsidence at a rate of about 4 mm/yr is occurring from Castaic Junction to San Fernando. The trend is evident in surveys made in 1985, 1984 and 1978. Subsidence is concentrated in the Newhall area and the Santa Clarita Valley. North of Castaic Junction, where the route lies in the bedrock of the San Gabriel Mountains, subsidence is absent. In the City of San Fernando, subsidence rates are 3 to 4 mm/yr. This rate decreases gradually southward along the Verdugo Mountains and towards the Santa Monica Mountains. Four leveling surveys made between 1971 and 1994 show that the vertical deformation across the Los Angeles Basin is complex.

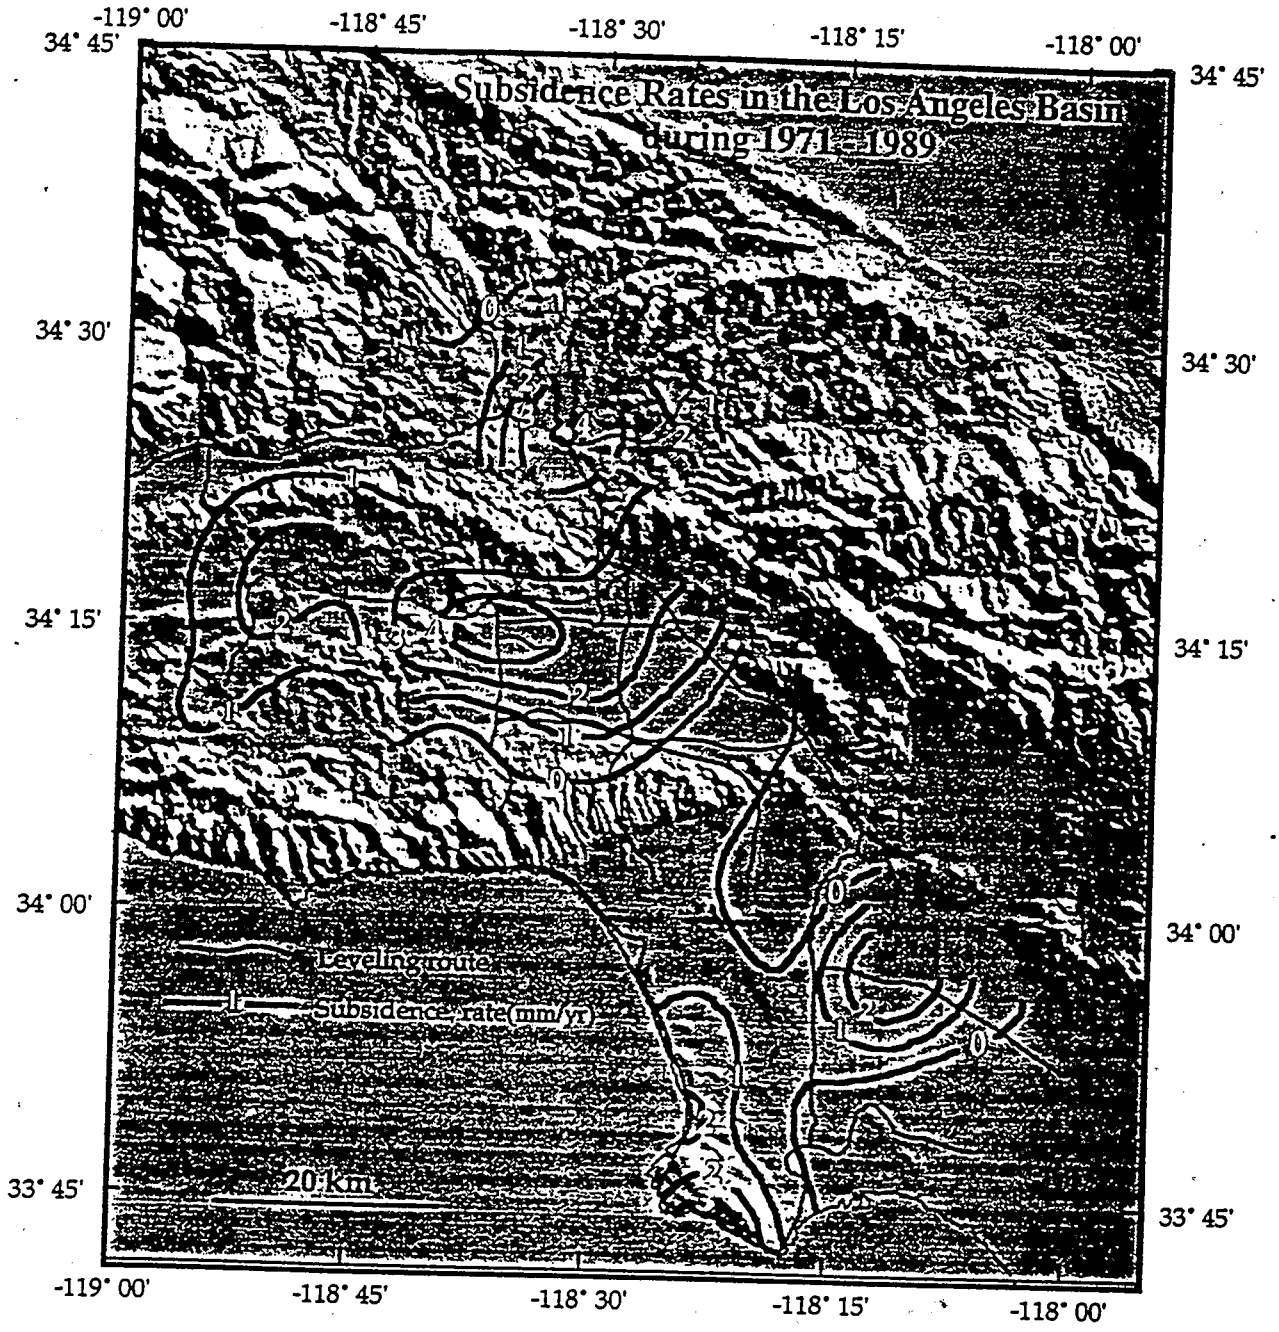

Figure 5. Subsidence rates in the Los Angeles Basin derived from leveling surveys made between 1971 and 1989. Solid black contours show where the data constrain the subsidence rate.

Subsidence at a rate of 15 mm/yr occurred between 1971 and 1989, relative to BMs outside the basin and south of the San Gabriel Mountains. In contrast, no such deformation occurred between 1989 and 1994. These observations agree well with water-levels measured at Well 906 (Figure 2), where low water levels were measured between 1975 and 1982, after which water levels rose and maintained a steady level.

(3) Saugus via Route 126 to Fillmore .

Leveling surveys made along this route between 1978 and 1975 indicate that up to 60 mm of subsidence occurred. The subsidence zone was 20 km wide and centered in the town of Piru. This deformation appears to have ceased after 1978. The difference between a 1989 and 1975 survey of the route shows at most 1.5 cm of deformation, where the greatest subsidence was observed between 1975 and 1978. The possibilities are that subsidence followed by recharge occurred and water levels have again reached those of 1975, or, that the 1978 survey contains systematic errors. A subsidence correction of only 1 mm/yr was applied to a 10 km section of the line based on the 1989 to 1975 elevation changes to remove the subsidence feature from the elevation changes. This results in a set of elevation changes which can then be attributed solely to the Northridge earthquake.

(4) Moorpark via Route 118 to San Fernando .

Observed subsidence along this route varied from 2 to 4 mm/yr and was greatest on the west side of the San Fernando Valley. A maximum subsidence correction of 4 mm/yr was applied along this leveling route. The observed subsidence corresponds to that measured along Interstate 5 where the two survey lines intersect (Figure 6).

(6) Fillmore via Moorpark to Thousand Oaks .

The subsidence along this leveling route ranged from 0.6 mm/yr at Fillmore to 2.5 mm/yr at Thousand Oaks. This was consistent with that observed along leveling routes Saugus to Fillmore and Moorpark to San Fernando.

(7) Chatsworth via Devonshire and Balboa Boulevards to San Fernando.

Subsidence was observed along this line from Chatsworth to about 3 km west of San Fernando. The subsidence rate increased from east to west across the San Fernando Valley and was greatest at Chatsworth where it was ~ 4 mm/yr.

(8) Chatsworth via Woodland Hills and Topanga Beach to Santa Monica.

Surveys made in 1974 and 1989 indicate subsidence along this route in the San Fernando Valley. The deformation is greatest from Chatsworth to Canoga Park and decreases as the leveling route rises into the Santa Monica Mountains. A hydrograph from Well 906 in Canoga Park (Figure 2) records a steady decline in water-level at

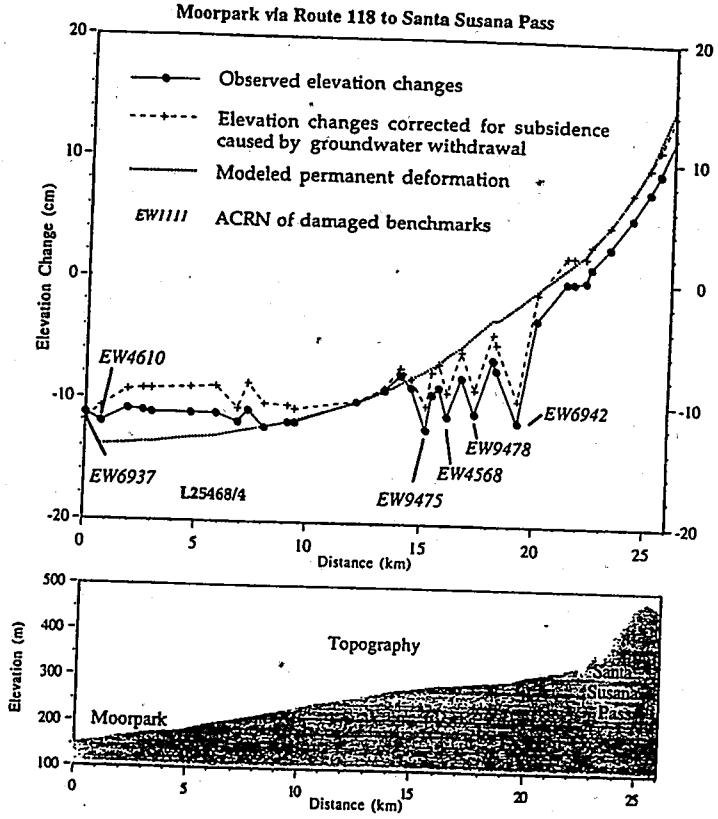

Figure 6. The observed, predicted and subsidence corrected elevation changes in Simi Valley along Route 118 (L25468/4). The PIDs (serial number) of benchmarks with an elevation changes which differs from the predicted coseismic elevation changes by more than 3 cm are labeled.

about 3 m in 30 years. Subsidence or deformation caused by landslides occurred along a 4-km-long section of the leveling route from Glenview to 3 km north of Topanga on Highway 27 between 1974 and 1989. The deformation is not, however, evident in the coseismic elevation changes which were formed by differencing surveys made in 1994 and 1989.

(13) Woodland Hills via Ventura to Cahuenga Boulevards to Interstate-10.
Localized subsidence occurred at a rate of about 1 mm/yr in the Sepulveda Dam Recreation Area between 1968 and 1974. One BM close to the Recreation area indicated subsidence as high as 3 mm/yr for that period. Subsidence is concentrated near the Dam and is negligible at distances of 5 km from it.

(14) Santa Monica via Redondo Beach to San Pedro.
There is evidence for subsidence in the vicinity of Redondo Beach. The deformation is evident over a 23-year period. The 1994 to 1989 elevation changes show that the feature is bowl shaped, centered at Redondo Beach and disappears towards Palos Verdes (Figure 7). The correction applied to this line is based on the 1994 to 1989 elevation changes, since the postseismic surveys yield high rates of subsidence which are not evident in the two most recent surveys of the area. The subsidence rate was thus estimated to be about 2 mm/yr at Redondo Beach. Redondo Beach lies at the northeast side of the Torrance oil field and it is probable that subsidence in Redondo Beach is due to oil and gas extraction [*U.S. Army Corp of Engineers*, 1990]. Groundwater levels have not declined significantly at Redondo Beach since 1975. Although groundwater pumping was extensive in the area, especially in the 1960's the effects have been diminished by sea water intrusions which helped recharge the aquifers [*U.S. Army Corp of Engineers*, 1990]. Non-tectonic deformation is also evident on the Palos Verdes peninsula. Surveys made in 1971, 1978 and 1989 revealed subsidence rates as high as 8 cm/yr in the vicinity of the Portuguese Bend landslide. Between 1994 and 1989 however, the deformation rate had decreased to 2.7 cm/yr.

(15) Huntington Park to Buena Park.
Subsidence is occurring west of the San Gabriel River at a maximum rate of 4 mm/yr. East of the river there is no subsidence. The correction applied to this line was determined from the 1994 to 1989 elevation changes since it was difficult to establish a zero subsidence level using the only other preseismic survey which was made in 1946.

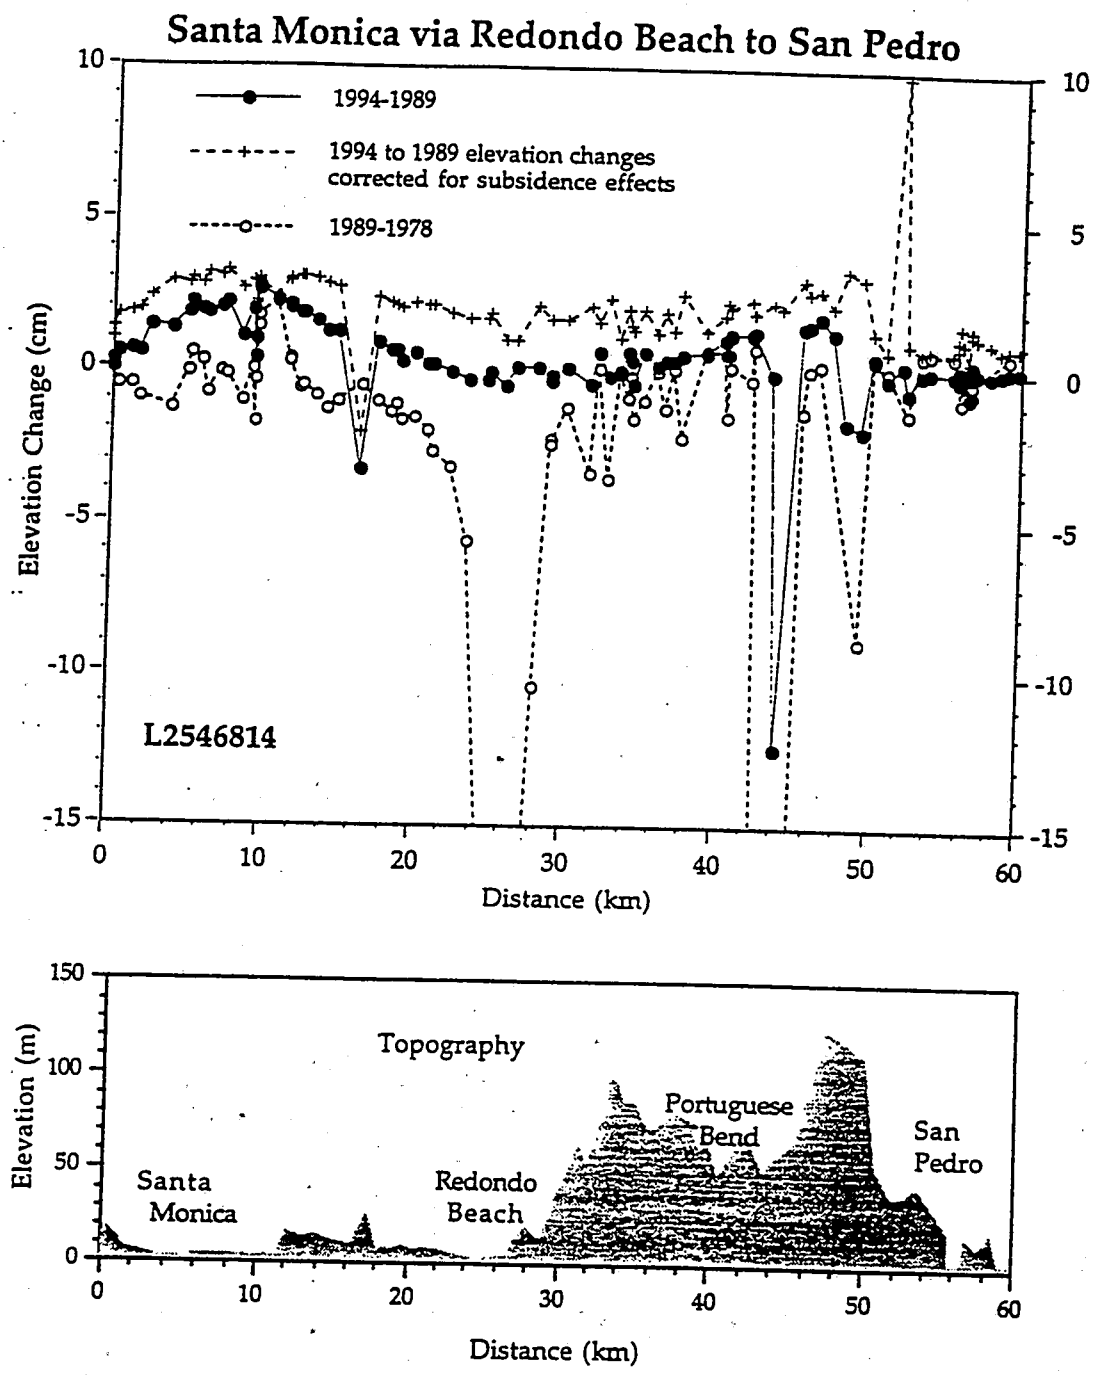

Figure 7. Leveling surveys made between 1978 and 1994 from Santa Monica to San Pedro (L25468/14) indicates subsidence at Redondo Beach.

1.3 Leveling Error Analysis

1.3.1 Random and systematic errors

To assign appropriate weight to each leveling measurement in the modeling process it is necessary to asses the accuracy of the data. This is accomplished by examining the difference between forward and backward leveling runs of each section between bench marks., or misclosures of the entire circuit of bench marks. Leveling surveys contain both systematic and random errors. Standards and practices for precision leveling are designed to reduce both types of errors [*Federal Geodetic Control Committee*, 1984]. The NGS classifies three standards of leveling; first, second and third-order. The most precise leveling is first-order. First and second order leveling has three subdivisions class 0, class 1, and class 2, class 1 being of higher precision than class 2. Procedures, equipment details, and precision are defined for each order and class.

Random errors.
The random error allowed to accumulate along a leveling line is expressed as $\alpha\sqrt{L}$, where L is the length of the line in kilometers. The value of α can be calculated in two ways. First, through agreement of the forward and backward measurements of the height differences between BMs and secondly through the misclosure of a leveling circuit. Using the former method, α is the standard deviation computed from several double run sections and is calculated as

$$\alpha = \frac{1}{N}\sum_{j}^{N}\sqrt{\frac{var_j}{D_j}} \qquad (1)$$

where N is the number of double run sections, D_j is the length in kilometers of the j^{th} double-run section, and var_j is the variance of that section. Double run sections are measured twice or more in a forward and backward direction. The variance is calculated as

$$var_j = \frac{1}{n}\sum_{i}^{n}\left(\bar{h} - h_i\right)^2 \qquad (2)$$

where n is the number of measurements of the j^{th} double-run section, h_i is the observed height and $\bar{h}$ is the average height of the observed runnings.

An alternative way to assess the accuracy of a leveling survey is to determine the cumulative height difference for the measurements associated with a loop in a survey. This is referred to as the misclosure of a leveling loop. Here α is calculated as $\alpha = E/\sqrt{L}$, where E is the misclosure in millimeters. In the absence of systematic errors the values of α calculated from the forward and backward differences and from misclosures should be about equal.

Systematic errors.
The principle sources of systematic errors in leveling data arise from incorrectly calibrated leveling rods and from atmospheric refraction effects. All surveys were tested for rod miscalibration by regressing the gradient of the topography against the elevation distance per kilometer [*Stein*, 1981]. If the survey was found to be contaminated by rod miscalibration errors then it was not used in this study. For example, a 1978 survey from Chatsworth to Woodland Hills showed a significant correlation between topography and elevation change. A 1974 survey of this route was therefore used to for the coseismic elevation changes along this line. All surveys in this analysis contained corrections for known systematic errors which occur in leveling, i.e., refraction, rod miscalibration, thermal expansion of the rods, collimation, and orthometric corrections.

1.3.2 Error assignment

For the first Order Class II leveling surveys made in 1994, the α values calculated using equation (1) ranged from 0.69 to 1.29 mm/km$^{1/2}$ (Table 1). The α values for the preseismic data set where calculated from the difference between the forward and backward leveling measurements (equation 1) and ranged from 0.93 to 1.89 mm/km$^{1/2}$ (Table 1).

The uncertainty in elevation change at a BM, δ_i, is given as

$$\delta_i^2 = \alpha_{pre}^2 + \alpha_{post}^2 + \left(0.3S_i\right)^2 \qquad (3)$$

where α_{pre} and α_{post} are the preseismic and postseismic α values respectively, and S_i is the subsidence rate at that point. The uncertainty in relative elevation change between two BMs, $\sigma_{(i,i+1)}$, is then

$$\sigma_{(i,i+1)} = \left[\left(\frac{\delta_i + \delta_{i+1}}{2}\right)^2 L\right]^{1/2} \qquad (4)$$

where L is the distance between BMs i and $i+1$.

2. NUMERICAL MODELING OF THE EARTHQUAKE DEFORMATION

2.1 Modeling Method

Our approach was first to find a model of the earthquake source that is most consistent with the displacement of the leveling BMs and GPS monuments and with independent seismological data, and then to identify the bench marks. that depart the most from the model (Figure 8). Bench marks with elevation changes that differed from the model by more than 3 cm (1.2 inches) were then visited for a preliminary site inspection by a Caltrans survey team.

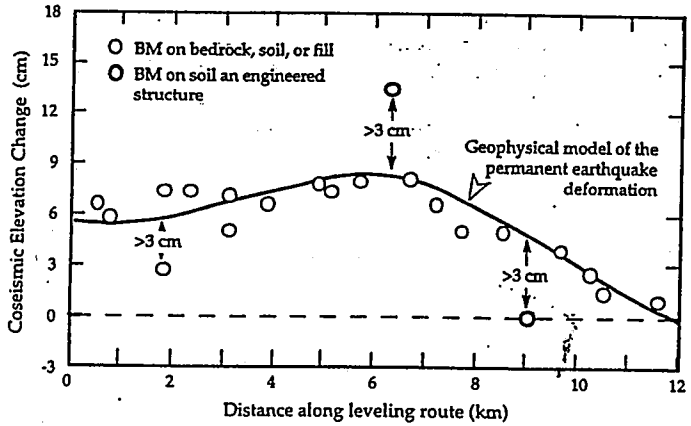

Figure 8. Schematic strategy to identify anomalous BMs. A geophysical model of the permanent earthquake deformation (*bold curve*) is consistent with the displacement of most BMs (*circles*). The subset of adjacent BMs displaced more than 3 cm (1.2") from the model are classed as 'disturbed' or anomalous, and those on engineered structures further distinguished (*bold circles*). Note that a BM with no coseismic elevation change (at km≈9) is nevertheless recognized as anomalous, because it has subsided more than 3 cm with respect to the model.

We treat the earth as a homogeneous elastic halfspace, a medium with a flat upper surface that extends to infinite depth, and assign elastic modulii (or stiffness) that approximate observed earth behavior. Into this medium we embed an elastic dislocation—a rectangular cut or fault—at a given location with a specified length, width, inclination, and orientation. We then calculate how slip (shear displacement)

of the fault will deform the earth's surface. This is comparable to making a cut inside a stiff block of rubber, displacing the two sides of the cut past each other a fixed amount, and measuring how the surface of the rubber block has deformed as a result of the internal cut. At every point where we have a geodetic observation of the earthquake deformation (vertical or horizontal), we calculate the predicted deformation per meter of slip on the fault. We then find the value of fault slip which minimizes the difference between the predicted and observed surface displacements. The observations are weighted such that the most precise observations carry the most weight, following *Marshall* [1991].

This method works well principally because the earthquake displacement field is predominantly long wavelength (smooth), whereas the displacements associated with structural damage or ground failure tend to be localized (Figure 8). In addition to the GPS and leveling observations, interferometric synthetic aperture radar satellite images confirm the simplicity of the overall spatial pattern of deformation [*Murakami et al.*, 1995; *Massonnet et al.*, 1993]. Because the Northridge earthquake struck on a 'blind' thrust fault [*SCEC & USGS*, 1994], in which the main fault slip does not reach the ground surface, the deformation field is relatively smooth everywhere .

The 617 leveling observations and 66 GPS-derived displacement vectors were simultaneously inverted to estimate the fault slip that occurred during the Northridge earthquake, which best satisfied the geodetic data [*Hudnut et al.*, 1996]. Since each GPS observation consists of three components of displacement there are thus 815 total observations. This modeling approach is based on elastic dislocation theory, which can be used to compute the displacements at a given point on the ground surface from a slip distribution model [*Okada*, 1992].

The modeled slip on the fault that caused the Northridge earthquake is shown in Figure 9 and the location of the fault, identical to that used by *Hudnut* [1996], is shown in Figure 10. This study differs from its predecessors [*Hudnut* et al., 1996],in that leveling observations were first corrected for subsidence and then introduced into the inversion as section elevation changes weighted by their uncertainty. The benefit in modeling section elevation changes is that no datum offset between the pre- and postseismic deformation need be identified. The uncertainty ascribed to each observation reflected the quality of the survey and error in any subsidence correction that had been applied to the data. The spatial coverage and density of the leveling data, in addition to the large number of sampled leveling sections, contribute substantial new information to the source inversion.

Distribution of coseismic slip on the Northridge fault

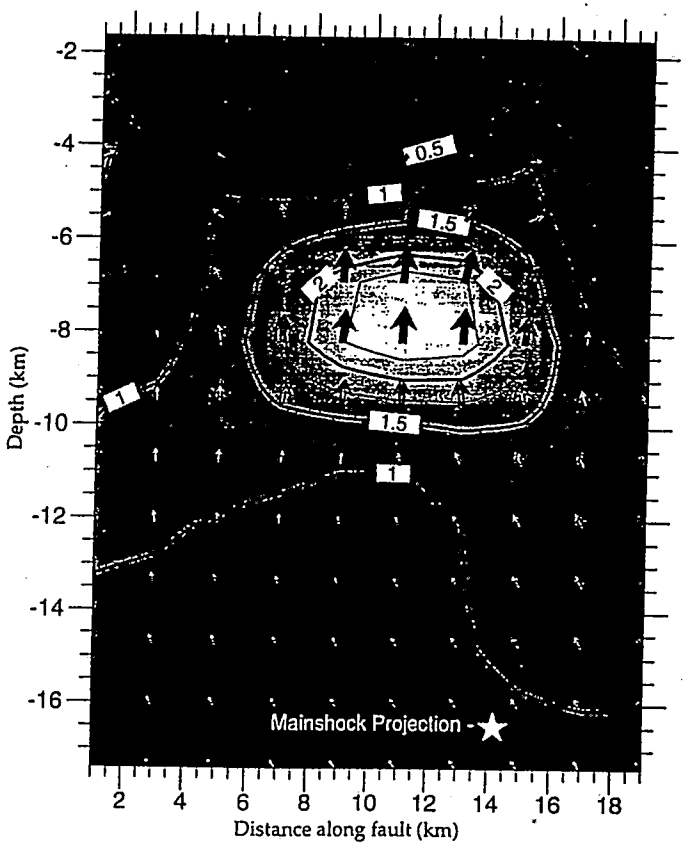

Figure 9. Model fault geometry used in the geodetic inversion and coseismic slip distribution. Slip amplitude (in meters) is shown by gray shading and contour intervals. Direction of slip is shown by the arrows.

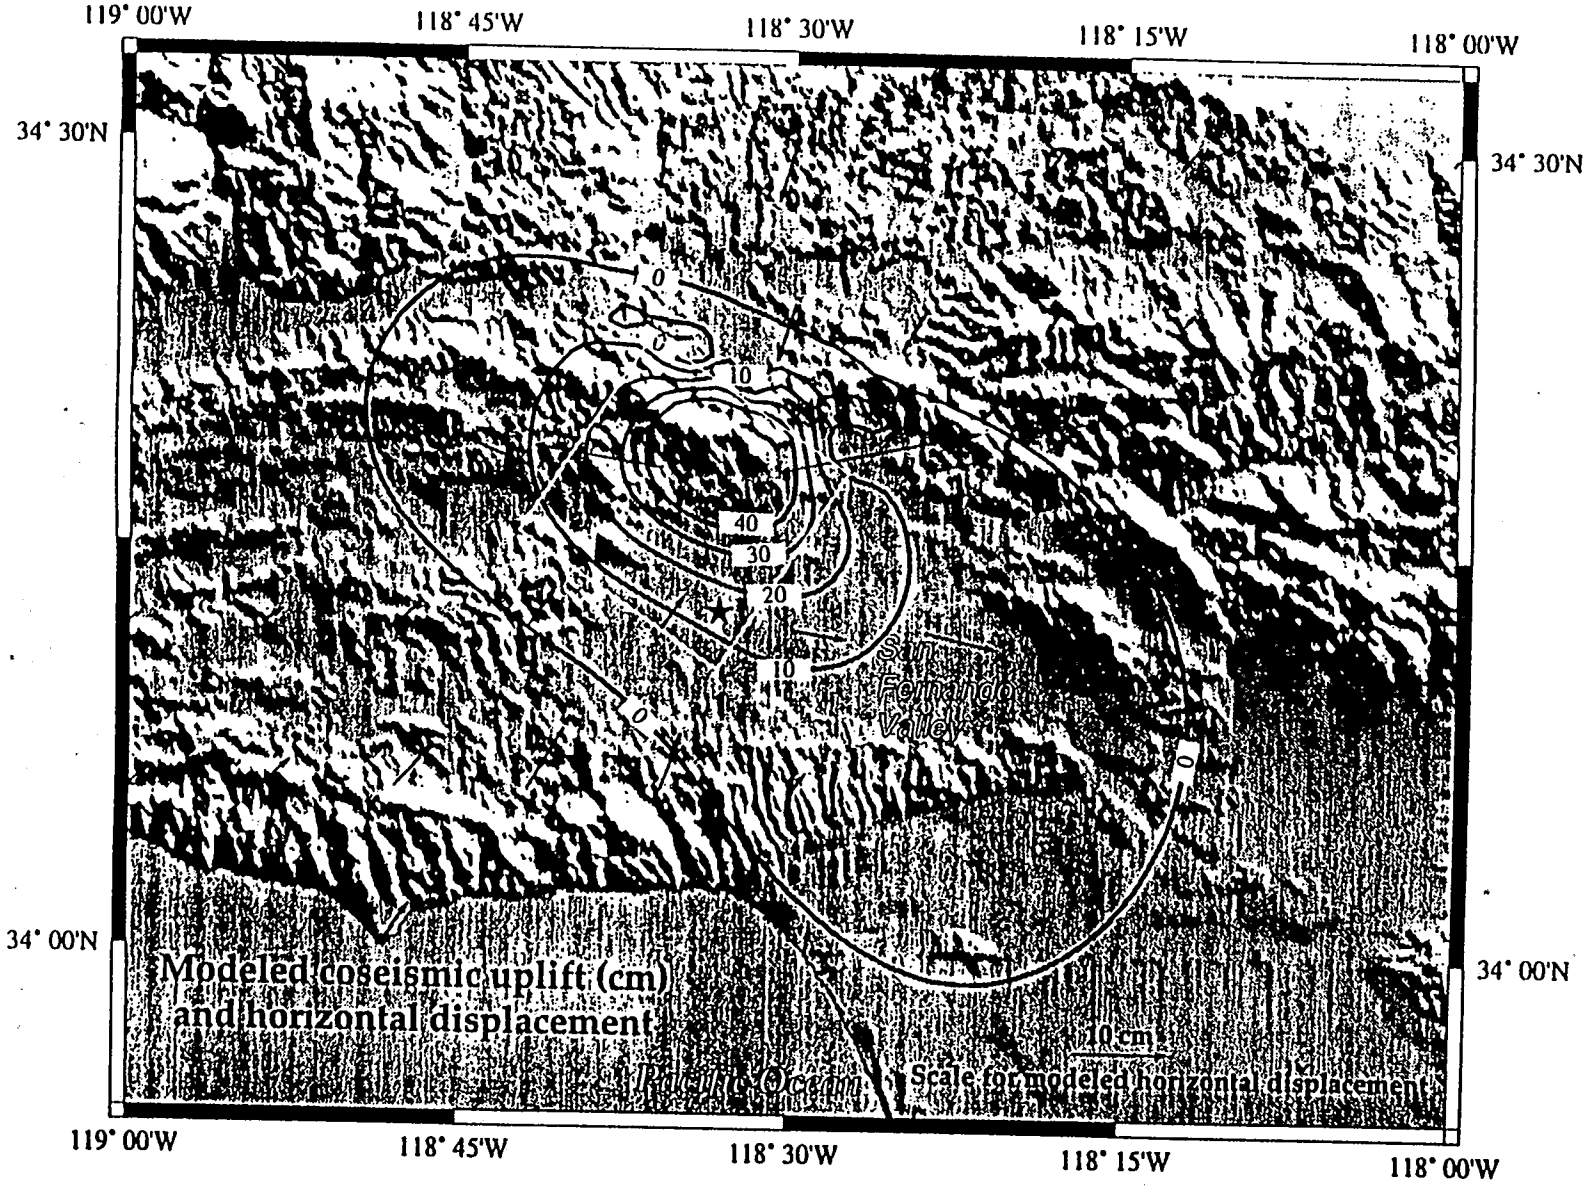

Figure 10. The predicted coseismic uplift (contours) and horizontal motion (vectors).

To isolate and remove leveling sections with large residuals, we first inverted all of the leveling and GPS data together, and then removed from the inversion leveling sections with residuals greater than 40 mm. The typical uncertainty of a section elevation observation (in other words, the uncertainty of the height change of one BM compared to an adjacent BM about 1 km away) was 10-15 mm, so 40 mm is about the 3σ or 95% confidence level of the section elevation change. We then re-ran the inversion. Any new 40 mm outliers were then removed from the revised model until the final model incorporated no residuals greater than 40 mm. Finally, this process was repeated with a 30 mm criteria, which represents the 90% confidence level.

2.2 Singular Value Decomposition Method

To estimate the slip distribution on an assumed fault plane, we applied Singular Value Decomposition or SVD. The displacement at a point on the Earth's surface caused by slip on a number of faults can be written as

$$\mathbf{u} = \mathbf{Gm} \qquad (5)$$

where G is a partial derivative matrix of functions that describes the fault geometry and elastic properties of the crust. The geodetic data, u, is a column vector that contains the measured coseismic displacements, and the matrix, m, is a column vector of slip values that must be estimated. To solve for m, both sides of equation (5) are multiplied by a matrix G^{-g} such that:

$$\hat{\mathbf{m}} = \mathbf{G}^{-g}\mathbf{u} = \mathbf{G}^{-g}\mathbf{Gm} \qquad (6)$$

where $\hat{\mathbf{m}}$ is the solution matrix, i.e., the coseismic slip. G^{-g} is the 'inverse' of G and SVD is used to estimate parameters in the G^{-g} matrix.

All geodetic inversions share the deficiency, that while displacement observations are made at the Earth's surface, we seek to resolve the fault geometry and slip at depth. The SVD matrix decomposition technique is used to estimate parameters when the data is insufficient to yield information and slip on certain parts of the fault . When the number of singular values in the matrix G^{-g} equals the number of unknown parameters (in this case, slip on the fault), then the technique is equivalent to least squares inversion of the data. Using a small number of singular values means that only those parts of the model that are well mapped by the data will be estimated.

We inverted the leveling section changes and their errors, along with the GPS estimates of displacement vector components and their associated errors (from Table 1 of [*Hudnut, et al.*, 1996]) to estimate the thrust and strike-slip components of slip on each subfault [*Larsen*, 1991]. The number of model parameters estimated was 260, and the number of data was 815 (617 section changes from leveling, plus 198 data from GPS, since each GPS displacement vector contains 3 components).

Rupture occurred on a plane 15 km long and 20 km down-dip. Slip was concentrated between 6 and 10 km depth where is was almost purely up-dip (Figure 9). The peak slip was about 3 m on the fault. We did not employ positivity or slip constraints in the inversions; in other words, slip was permitted to be positive or negative at all sites on the fault surface. In the SVD method, when the eigenvalue matrix is truncated, a form of smoothing is implemented; no other smoothing was implemented [*Larsen*, 1991]. We retained 29 singular values, fitting the geodetic data well and, producing a solution in accord with seismic evidence, and yielding a total seismic moment of 1.5×10^{19} N-m (equivalent to a moment-magnitude M=6.75). Other solutions yielded qualitatively similar slip distributions in the range $26 < k < 31$, where k is the number of retained singular values. Within this stable range, the seismic moment increased from 1.54 to 1.74×10^{19} N-m, and the normalized-root-mean-square (nrms) residuals decreased slightly. Although a more rigorous selection of the optimal result from this approach is possible using an F-test [*Parker*, 1977] we made our selection by inspection, in an attempt to fit the largest number of BMs as closely as possible while avoiding mapping errors or anomalous, BMs into the slip values. This minimized the number of BMs falsely identified as anomalous,.

3. FINDINGS

3.1 Surface deformation and slip distribution

The predicted permanent surface displacements calculated from the model are shown in Figure 10 and on the map. The model can be used to estimate the displacement, tilt, strain, or stress of any point in the greater Los Angeles region. The predicted surface deformation field is dominated by northeast-southwest contraction and east-west expansion (Figure 10). The Santa Susana Range and the San Fernando Valley were elevated by 10 to over 40 cm. The amount of uplift increased from south to north across the valley and was greatest in the Santa Susana Range where it was up to 50 cm. The vertical deformation decreases to zero within 15 to 20 km of the epicentral area and is almost absent in the Santa Monica Mountains.

3.2 Anomalous bench marks in the Los Angeles basin

Each bench mark in the coseismic data set was classified by the type of structure upon which it is located (Table 2). The five classifications are: bridges, bridge piers and abutments (class B), culverts and retaining walls (class S), electrical towers (class T), buiiding foundations (class F), catchment basins (class C), and all others, such as BMs set in roads, curbs, bedrock, sediment or engineered fill (class N), (see Tables 2 and 3).

The deformation observed at 997 of the coseismic leveling BMs could be explained exclusively by the permanent coseismic deformation of the Northridge earthquakes. Residuals in excess of 3 cm or more were observed at 40 BMs, and these BMs suggest that shaking effects contributed to their movement. The few GPS monuments showing residuals greater than 3 cm are discussed in detail by *Hudnut et al.*, (1996), few of the GPS stations are placed in engineered structures or fill. Possible causes of the disturbance to leveling BMs include ground shaking [*Wald & Heaton*, 1994], surface cracking and faulting [*Hecker, et al.*, 1995], landslides [*Harp & Jibson*, 1995], settlement and liquefaction [*Holzer, et al.*, 1996], or damage to structures where BMs are situated [*Buckle*, 1994; *Caltrans*, 1994]. Culverts and retaining walls displayed the largest percentage of damaged BMs (Table 3). Only one BM near an electricity tower had a residual of 3 cm or greater. Although not on the tower itself, the BM was within 30 m of the structure. Each of the BMs that had significant residuals is listed in Table 3 and driving directions and access instructions are given in Appendix I.

Table 2. Infrastructure on which the BMs where placed. 'Number Damaged' is the number of BMs with observed deformation that differs by 3 cm from the predicted deformation.

Infrastructure	Class	Total Number	Number Damaged
Bridges, piers and abutments	B	226	5
Culverts and retaining walls	S	144	9
Electricity towers	T	12	1
Catchment basins	C	113	6
Building foundations	F	27	1
Others	N	457	18

Table 3. Anomalous BMs. For these BMs, the difference between modeled and predicted elevation change between adjacent BMs exceeds 3 cm. Site classes: B, bridges, bridge piers and abutments; S, culverts and retaining walls; T, electrical towers; F, building foundations; C, catchment basins; N, all others.

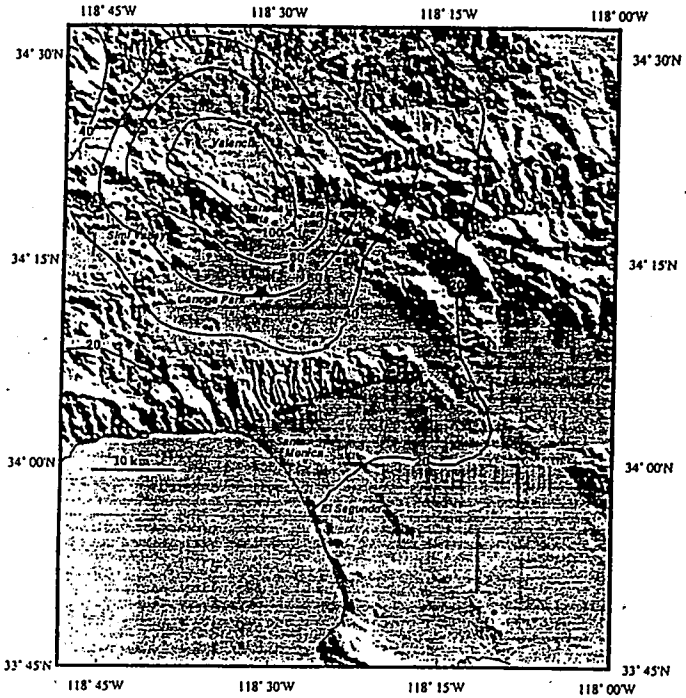

Figure 11. Contours of observed rotated peak ground velocity (cm/sec) *Wald et al.* [1996]. Black dots indicate damaged benchmarks and the star shows the location of the mainshock

The majority of the disturbed, or anomalously displaced, BMs are concentrated in the Granada Hills, Santa Clarita Valley and along Route 118 between Fillmore and the junction of Route 118 with Interstate 5 (Map 1). These are areas where the peak ground velocity was calculated to be greatest, between 80 to 100 cm/second [*Wald, et al.*, 1996] (Figure 11). The majority of landslides occurred in these foothill areas. In contrast, only three BMs south of downtown Los Angeles had large residuals. The coseismic displacements caused by the Northridge earthquake were quite small at these distances. One BM at El Segundo (No. 18, Map 1), where the peak ground velocity was about 20 cm/second, is located in sandy soil and may have shifted as a result of ground shaking and settlement. BMs 19 and 20 (DY2538 and DY2535, see map) are located in Long Beach; both are situated on or near concrete catchment basins which may have been damaged in the earthquake.

3.3 Disturbance related to landslides and liquefaction

Some 15,000 landslides were mapped following the Northridge earthquake [*Harp & Jibson*, 1995]. Five of the anomalous BMs are found on or within several hundred meters of the slides, suggesting that the BMs were moved downslope with the underlying material (BMs 1, 2 , 22, 23, and 27 on the map and in Table 3). BM 1 (EW9445) is in a building foundation that may have suffered from shaking or landslide effects. Roads, pipelines, and structures sited near the slides may also be affected by continuing downslope movement of the landslides, particularly during periods of heavy rainfall. BM 27 (EW4865) is in the headwall a concrete bridge, and might indicate incipient damage to the bridge.

Eighteen sites where near surface materials were subject to shaking-induced liquefaction were identified following the earthquake, as well as 4 additional sites of possible liquefaction [*Holzer et al., 1996; U.S. Geological Survey Staff*, 1996]. Two BMs are located close to the liquefaction regions (BMs 29 in Simi Valley, and BM 35 in the northern San Fernando Valley, Table 3 and map). BM 29 (EW6942) is located in railroad bridge 38.40, above a double flood-control culvert in Simi Valley. Thus the bridge and culvert may have settled or been damaged as a result of shaking-induced liquefaction. In contrast, some twelve BMs located within 300 m of the mapped liquefaction sites were undisturbed, demonstrating that liquefaction is generally a localized phenomenon.

3.4 Disturbance related to ground fractures

Of the three principal sites of surface faulting or cracking (Granada Hills, Northridge-Reseda, and Potrero Canyon), only the Granada Hills are crossed by the precision leveling lines used in this study (Figure 12). Three routes traverse the Granada Hills faulting zone; 8 BMs locating within 500 m of the mapped zone of faulting [*Hecker, et al.*, 1995]. None of the BMs located near the ground cracking are disturbed (Figure 13). BM 39 (EW4844), located in sediment 0.5 km north of the cracking, subsided by 13 cm, and BM 38 (AA3236), 2 km south of the cracking, is disturbed by 3 cm. The absence of any consistent offset of the elevation change profile across the Granada Hills faulting zone demonstrates that the faulting is superficial, a finding in accord with the conclusions of *Hecker et al* [1995]. If the fault slip extended to a depth of a few kilometers, most of these BMs would be displaced, and the elevation change would diminish with distance from the fault zone.

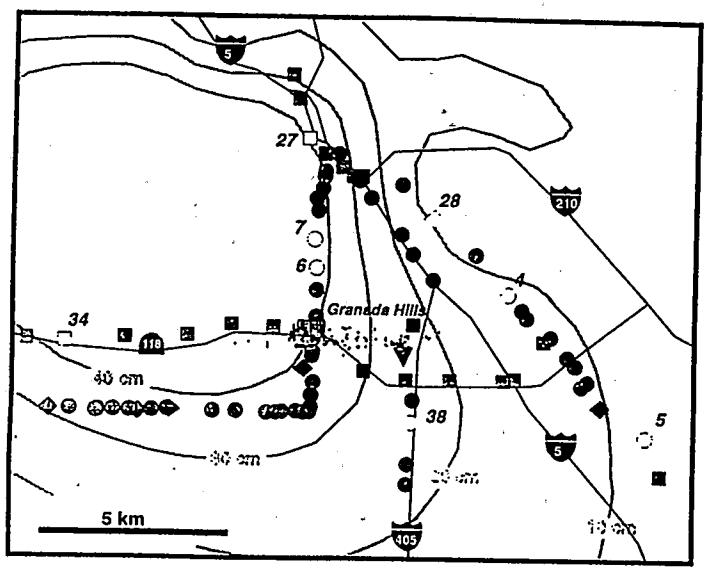

Figure 12. Granada Hills. Damaged bench marks are shown as white circles and numbered as shown in Map 1. Gray lines indicate the modeled uplift contours and small black dots indicate ground cracking (*Hecker et al.*, 1995).

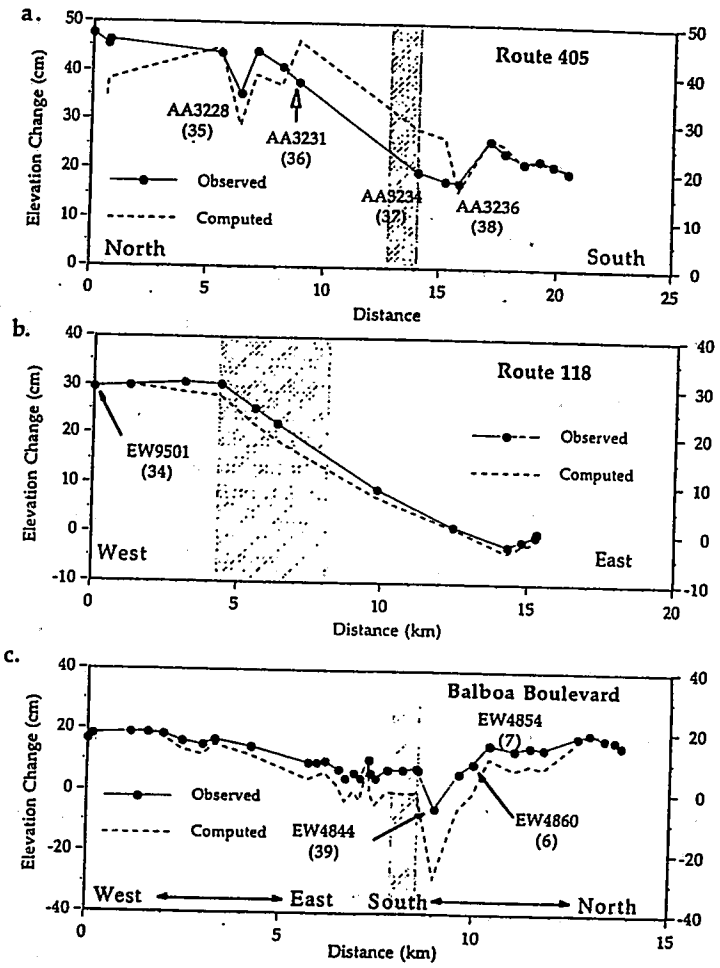

Figure 13. Computed and observed vertical deformation in Granada Hills. a) Route 405, b) Route 118 and c) along Balboa Boulevard. Damaged benchmarks are labeled as shown in Map 1 and gray shading represents areas where surface cracking was mapped.

3.5 Disturbance related to fault zone materials

Five anomalous BMs are located within or very near fault zones (BM 4, 5, 24, 25, and 34 in Table 3 and the map). Because the material in a fault zone is often quite weak, small amounts of "triggered" or "sympathetic" slip are often found to accompany large earthquakes. BM 4 (EW2515) lies in the Santa Susana fault zone that ruptured during the 1971 San Fernando earthquake. The 3.3-cm disturbance may indicate a small amount of near-surface slip on the Santa Susana fault triggered by the Northridge earthquake. Several studies have pointed out that the 1971 and 1994 earthquakes are in several respects closely related [*Mori et al.*, 1995; *Stein et al.*, 1994]. BM 24 and 25 lie in the San Gabriel fault zone; while the fault itself is believed to be inactive, pulverized rock or "gouge" in the fault zone may settle when shaken.

3.6 Change of flood plain boundaries

Vertical elevation changes associated with an earthquake cause the topographic slope to be altered and this in turn can result in shifts in flood plain boundaries. The elevation changes created by the Northridge earthquake caused minor changes in flood plain levels. The horizontal shift in flood plain boundaries, dx, is determined by subtracting the postseismic position of the flood plain boundary from its preseismic position. This is calculated using

$$dx = x - x' = y\left(\frac{1}{\tan\alpha} - \frac{1}{\tan(\alpha+\beta)}\right)$$

where x is the preseismic and x' the postseismic position of the flood boundary, α is the preseismic topographic slope, β is the change in slope caused by the Northridge earthquake and y is the original height of the flood surface above a certain point (Figure 14). In the Northridge area the topography generally became steeper as a result of the thrust earthquake. The horizontal shift in flood plain level is greatest where the topographic slope is most gentle and where the earthquake-associated ground tilt is largest.

In the Canoga Park, Reseda and Sepulveda Dam areas, where the topography is very gentle, flood plain changes were small since the elevation changes were less than 10 cm. Where elevation changes were large, the topography was steeper and the effect of the coseismic uplift on the topography was small. Elevation changes were greatest in the Granada Hills area and the Santa Susana Mountains. The 300 m topographic contour level, which runs through Chatsworth and Granada Hills and borders the Hansen Dam and Chatsworth Reservoir, received the largest shifts. The topographic

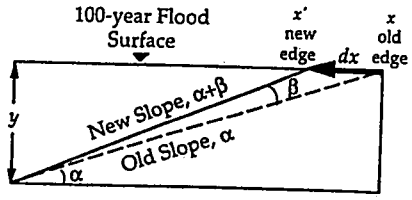

Figure 14. The tilt β of the basin, associated with the permanent earthquake deformation, causes the border of the 100-year flood plane to shift by distance dx.

gradient ranged from 1/41 (1.4°) to 1/115 (0.5°) and the corresponding northward shift in the 300 m contour level ranged from one meter to 28 meters. The change in the flood plain boundary around the Chatsworth Reservoir was at most 12 meters while at the Hansen Dam the shift in contour level was less than one meter and insignificant. The change in tilt (metres per kilometer) across the San Fernando Valley and the Santa Susana Mountain Range are contoured in Figure 15. The tilt is positive towards the north, i.e., uplifted towards the north in the valley, and negative on the north side of the Santa Susana Mountain range.

Flood plain areas are affected by the rate of delivery of floodwater to the plain. Since the Northridge earthquake altered the gradient of stream channels the change in gradients for streams flowing into the San Fernando Valley were also calculated. The Browns Canyon, Limekiln and Aliso Canyon are three main stream channels which drain into the San Fernando Valley from the Santa Susana Mountain Range. The change in gradient for the Brown Canyon is about 4.2 to 5 cm/km (0.0025°) in the foothills and as far as Chatsworth. Gradient changes along the Limekiln Canyon were slightly larger at ~6.5 cm/km (0.0037°). Between the 500 m and 300 m contour intervals, the change in gradient along the Aliso Canyon and Aliso Canyon Wash was 5 to 7 cm/km (0.0028° to 0.004°). The gradient change in stream channels in the Santa Susana Mountains was therefore very small.

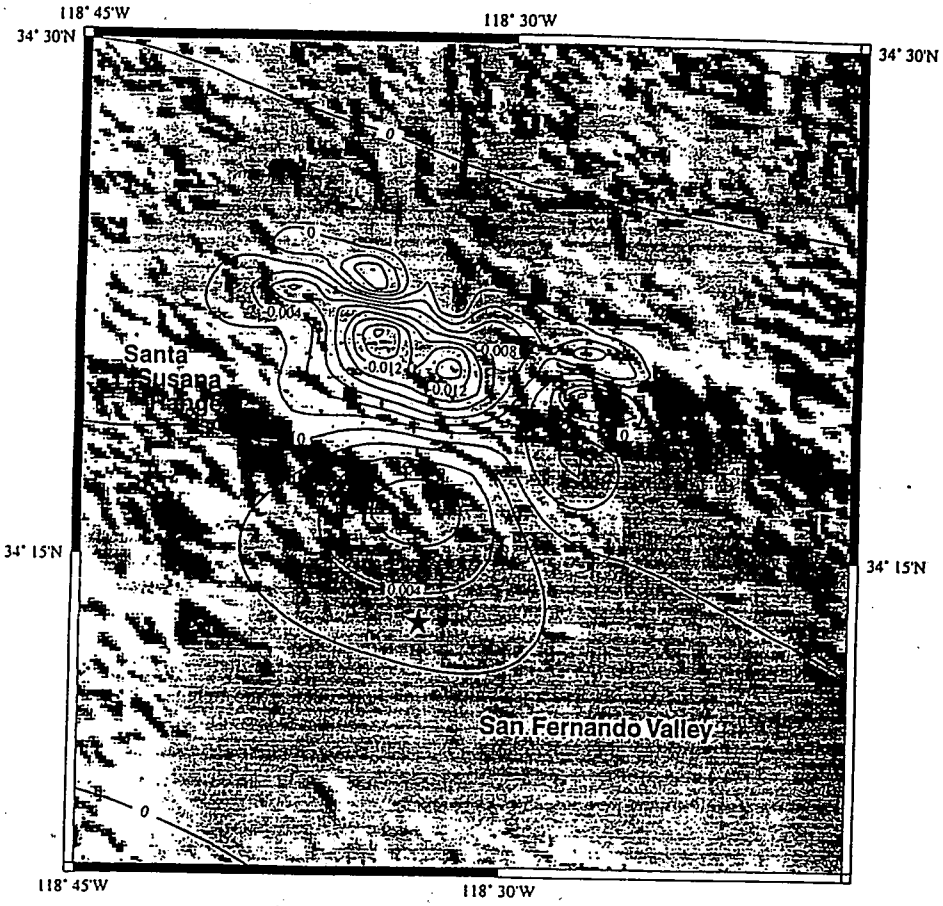

Figure 15. The change in gradient caused by the Northridge earthquake. Positive tilt implies the ground was uplifted towards the north. Units are meters pre kilometer.

4. VALUE OF THE REPORT

Prior to publication of this report, several agencies have requested data from us or asked for assistance in interpreting our findings for engineering or surveying purposes. Briefly, these include the following:

- The National Geodetic Survey has so far received and filled about 100 requests for new heights and coordinates in southern California from the restored network.
- Caltrans used the pre- and post-earthquake elevation changes to assess subsidence and deformation associated with tunneling for the Metropolitan Transit Authority's subway extension [*Satalich*, 1996]. Such use of the restored network will continue as the MTA expands, and thus the restored leveling network promises to improve the safety of the drilling operations.
- NASA's Jet Propulsion Laboratory has requested and received our map of long-term subsidence in metropolitan Los Angeles to evaluate and interpret deformation inferred from a new generation of radar satellites, which measure height change by forming an interferogram with three successive radar images of the topography [e.g., *Massonnet, et al.*, 1993].
- The City of Simi Valley has used the anomalous BM listing and the sites of liquefaction and landslides to assess damage and urban reconstruction issues. The U.S. Geological Survey prepared a set of deformation profiles and maps with the surface street grid included at their request, which aided the Simi Valley deliberations.
- The California Seismic Safety Commission requested and received a preliminary version of the map to compare elevation change measured by surveying with the distribution of ground cracking mapped by its members and independent geologists. The Commission seeks to evaluate the extent and cost of damage to the built environment directly attributable to surface faulting in a blind earthquake.
- Scientists at the U.S. Geological Survey and the California Institute of Technology used the coseismic elevation changes developed in this report to study the earthquake source and rupture propagation. This effort has lead to improved models of earthquake hazards, and a better understanding of the causes of earthquake shaking [*Wald, Heaton, & Hudnut*, 1996].
- Geologists at the U.S. Geological Survey are using the coseismic elevation changes along with detailed surface mapping to determine if ground cracks in the Granada Hills were caused by slip on a fault or by shaking and liquefaction.

5. RECOMMENDATIONS

Immediately after the Northridge earthquake, the vast majority of structures were assessed for earthquake effects solely by visual inspection. Thus subtle or hidden damage may have escaped detection. The settlement or uplift of the structures deduced from the movement of bench marks (BMs) offers a new tool to identify potentially weakened structures. A similar approach was followed after the M=7 Cape Mendocino earthquake in northernmost California [*Stein, et al.*, 1996]. BM disturbance revealed damage to a major bridge crossing the Eel River, as well as road and rail embankment failures caused by landslides and liquefaction. The structures identified by anomalous BMs in the Los Angeles area may thus be in a weakened state, making them vulnerable to shaking during future earthquakes. Thus we strongly recommend that all 40 sites of anomalous BMs be examined by structural engineers for follow-up evaluation. Driving directions and a preliminary inspection of each BM is included in Appendix I.

In addition, we suggest that a higher percentage of geodetic monuments be emplaced and measured precisely on critical transportation arteries, structures, and lifelines. This will ensure faster and more accurate post-earthquake damage assessments in the future. Traditionally, BMs are placed on frontage roads and less traveled road and rail routes to ensure the ease of access by surveyors and engineers. BMs have been located in bridge abutments and approaches when convenient for surveyors. Instead we argue that the need to identify a weakened structure supersedes the ease of access, and thus freeways and overpasses should be monumented so that rapid post-earthquake evaluation is possible. To be most effective, BMs should be placed on both sides of each bridge or overpass, and also within 500 m of the ends of the bridge to provide a stable reference site for comparison to the bridge.

NAME: Y 898
1.5 MI NW FROM SAUGUS.
1.5 MILES NORTHEAST ALONG THE SOUTHERN PACIFIC COMPANY RAILROAD FROM THE STATION AT SAUGUS, 2 1/4 TELEPHONE POLES NORTHWEST OF MILEPOLE 449, AT THE BONELLI RANCH, AT 24-INCH CONCRETE PIPE CULVERT 449.10, IN THE TOP OF THE SOUTHEAST END OF THE SOUTHWEST CONCRETE HEAD WALL, 12.2 FEET SOUTHWEST OF THE SOUTHWEST RAIL, AND ABOUT 3 FEET LOWER THAN THE TRACK.
1.7 KM (1.05 MI) EASTERLY ALONG THE SOUTHERN PACIFIC RAILROAD FROM THE JUNCTION OF CINEMA AVENUE IN SAUGUS, NEAR THE SOUTHEAST END OF THE SOUTHWEST CONCRETE HEADWALL OF CULVERT NUMBER 449.10 UNDER THE TRACK, 3.8 M (12.5 FT) SOUTHWEST OF THE NEAR RAIL, 1.1 M (3.6 FT) BELOW THE LEVEL OF THE TRACK, AND ACROSS THE TRACK FROM A LARGE METAL BUILDING ENCLOSED BY A CHAIN-LINK FENCE.
March 1996 Caltrans Inspection: No visible damage

PID: EW4610 Residual = 5.0 cm Type N
NAME: 37 8
IN MOORPARK, AT THE INTERSECTION OF HIGH STREET AND WALNUT STREET, IN TOP OF A CONCRETE CURB. 13.7 M (44.9 FT) WEST OF THE CENTER OF WALNUT STREET, 7.4 M (24.3 FT) NORTH OF THE CENTERLINE OF HIGH STREET AND 0.2 M (0.7 FT) ABOVE THE HIGH STREET SURFACE. IN MOORPARK, AT THE INTERSECTION OF WALNUT AND HIGH STREETS, IN THE NORTH CURB OF HIGH STREET, 14.3 M (46.9 FT) WEST OF THE CENTER OF WALNUT STREET, 7.2 M (23.6 FT) NORTH OF THE CENTERLINE OF HIGH STREET, AND 0.1 M (0.3 FT) ABOVE THE LEVEL OF THE STREETS.
March 1996 Caltrans Inspection: No visible damage

PID: EW6937 Residual = 5.0 cm Type S
NAME: K 1295
0.6 KM (0.35 MI) WEST ALONG THE SOUTHERN PACIFIC RAILROAD FROM ITS JUNCTION WITH STATE HIGHWAY 23 IN MOORPARK. 24.0 M (78.7 FT) WEST OF A DERAILING RAILROAD SWITCH, 8.6 M (28.2 FT) NORTH OF THE NEAR RAIL, 4.4 M (14.4FT) SOUTH OF THE SOUTH HEADWALL FOR A CONCRETE BOX CANAL, 1.2 M (3.9FT) BELOW RAILROAD TRACKS AND 0.15 M (0.5 FT) BELOW GROUND SURFACE.
0.6 KM (0.35 MI) WESTERLY ALONG THE SOUTHERN PACIFIC RAILROAD FROM THE JUNCTION OF STATE HIGHWAY 23 IN MOORPARK, 32.1 M (105.3 FT) NORTH OF THE CENTERLINE OF POINDEXTER AVENUE, 23.2 M (76.1 FT) WEST OF THE WEST END OF A

RAILROAD SIGNAL CONTROL BOX, 8.6 M (28.2 FT) NORTH OF THE NEAR RAIL, 4.3 M (14.1 FT) SOUTH OF THE SOUTH WALL OF A DITCH, AND 1.0 M (3.3 FT) BELOW THE LEVEL OF THE TRACK. NOTE–THE DISK IS ENCASED IN A 4-INCH PVC PIPE WITH A SCREW CAP AND IS RECESSED 0.1 M (0.3 FT) BELOW THE GROUND SURFACE.
March 1996 Caltrans Inspection: No visible damage

PID: EW5012 Residual = -4.4 cm Type B
NAME: Y 984
2.9 MI E FROM SAUGUS.
2.9 MILES EAST ALONG THE SOUTHERN PACIFIC COMPANY RAILROAD FROM THE STATION AT SAUGUS, 0.3 MILE EAST OF MILEPOLE 448, AT AQUEDUCT UNDERPASS 447.70, IN THE TOP OF THE CENTER OF THE NORTHWEST CONCRETE HEAD WALL, 18.4 FEET NORTHWEST OF THE NORTHWEST RAIL, AND ABOUT 1.5 FEET LOWER THAN THE TRACKS.
2.05 MILES WEST ALONG SOLEDAD CANYON ROAD FROM THE BRIDGE OVER THE SANTA CLARA RIVER, 2.9 MILES EAST OF THE STATION AT SAUGUS,IN TOP OF THE CENTER OF A CONCRETE HEAD WALL FOR THE LOS ANGELES COUNTY AQUEDUCT, UNDER THE RAILROAD, DIRECTLY IN LINE WITH THE CENTER LINE OF THE AQUEDUCT. NOTE- HEADWALL IS COMPLETELY BURIED, DISK IS 4 INCHES UNDERGROUND, 36.8 FT. SOUTHEAST OF SOUTHEAST CURB, SOLEDAD CANYON ROAD, 20.6 FT. EAST OF TELEPHONE POLE, 18.7 FT NORTHWEST OF NORTHWEST RAIL.
3.9 KM (2.40 MI) EASTERLY ALONG THE SOUTHERN PACIFIC RAILROAD FROM THE JUNCTION OF CINEMA AVENUE IN SAUGUS, NEAR THE CENTER OF THE NORTH HEADWALL OF A CULVERT SPANNING THE LOS ANGELES AQUEDUCT, 39.2 M (128.6 FT) WEST OF THE SOUTH LEG OF A SIGN (CANYON COUNTRY CHAMBER OF COMMERCE) , 11.3 M (37.1 FT) SOUTH OF THE SOUTH CURB OF SOLEDAD CANYON ROAD, 5.7 M (18.7 FT) NORTH OF THE NEAR RAIL, 0.5 M (1.6 FT) BELOW THE LEVEL OF THE TRACK, 0.3 M (1.0 FT) EAST OF A WITNESS POST, AND 0.1 M (0.3 FT) BELOW THE GROUND SURFACE.
March 1996 Caltrans Inspection: No visible damage

PID: EW6899 Residual = -11.6 cm Type S
NAME: M 1296
SAN FERNANDO.
1.6 MILE SOUTHEAST ALONG SAN FERNANDO ROAD FROM ITS JUNCTION WITH I 240 AND I 5, THENCE, 210 FT. NORTHEAST AND ACROSS TRACKS FROM THE JUNCTION OF SAN FERNANDO ROAD AND BLEDSOE STREET, AT THE SOUTH-EAST CORNER OF THE JUNCTION OF BLEDSOE STREET AND A PAVED ROAD RUNNING PARALLEL WITH TRACKS. 51.5 FT. SOUTHEAST OF CENTER LINE OF BELDSOE STREET, 54.5 FT. NORTHEAST OF THE CENTER LINE OF THE PAVED ROAD, 12.9 FT. SOUTHWEST OF THE NORTHEAST CORNER OF THE FENCE LINE AROUND MERLE NORMAN COSMETICS GROUNDS, 3.5 FT. WEST OF A HALF ARCH BRICK RETAINING WALL SUPPORTING THE FENCE, ACCESS HAD THROUGH A PLASTIC CAP FLUSH WITH THE GROUND.
RECOVERED IN GOOD CONDITION. NOTE–THE DISK IS STAMPED M 1296 1977, NOT M 1296 1978.
IN SLYMAR, AT THE INTERSECTION OF SAN FERNANDO ROAD AND BLEDSOE STREET, 64.0 M (210.0 FT) NORTHEAST OF THE CENTER OF THE ROAD, 16.6 M (54.5 FT) NORTHEAST OF THE CENTER OF A PAVED ROAD, 13.8 M (45.3 FT) SOUTHEAST OF AND LEVEL WITH THE STREET, 1.0 M (3.3 FT) WEST OF A FENCE CORNER WITH A SIGN (MERLE NORMAN COSMETICS) ATTACHED. NOTE–THE DISK IS ENCASED IN A 4-INCH PVC PIPE AND IS FLUSH WITH THE GROUND SURFACE.
March 1996 Caltrans Inspection: No visible damage

PID: EW7051 Residual = 7.5 cm Type S
NAME: P 1374
0.5 KM (0.3 MI) SOUTH FROM SAUGUS ALONG THE SOUTHERN PACIFIC RAILROAD FROM ITS STATION AT SAUGUS, IN TOP OF AND 0.5 METER (1.5 FT) SOUTH OF THE NORTH END OF A HEADWALL FOR A 60-INCH INDUSTRIAL CULVERT UNDER THE RAILROAD AND SAN FERNANDO ROAD, ON THE EAST EDGE OF THE CLARA RIVER, 48.3 METERS (158.5 FT) WEST ACROSS THE ROAD FROM THE WEST RAIL, 26.8 METERS (88 FT) WEST OF THE CENTER OF THE ROAD. MARK IS ABOVE LEVEL WITH THE ROAD.
1.9 KM (1.20 MI) NORTHWESTERLY ALONG SAN FERNANDO ROAD FROM THE JUNCTION OF SIERRA HIGHWAY IN NEWHALL, THENCE 3.8 KM (2.35 MI) NORTHWESTERLY ALONG THE SOUTHERN PACIFIC RAILROAD, IN TOP OF AND 0.5 M (1.6 FT) SOUTH OF THE NORTH END OF THE WEST CONCRETE HEADWALL OF A CULVERT UNDER THE RAILROAD AND THE SAN FERNANDO ROAD, 48.3 M (158.5 FT) WEST OF THE NEAR RAIL, 14.0 M (45.9 FT) WEST OF THE CENTERLINE OF THE SOUTHBOUND LANES OF THE ROAD, 4.9 M (16.1 FT) WEST OF A CHAIN-LINK FENCE, 0.3 M (1.0 FT) BELOW THE LEVEL OF THE ROAD, AND 0.1 M (0.3 FT) SOUTH OF A CHAIN-LINK GATE POST.
March 1996 Caltrans Inspection: No visible damage

PID: DY2535 Residual = -11.6
PID: DY2535 Type N
NAME: 93 A
IN LONG BEACH, AT THE INTERSECTION OF CHERRY AVENUE AND WARDLOW ROAD, 14.0 M (45.9 FT) WEST OF THE CENTERLINE OF THE SOUTHBOUND LANES OF THE AVENUE, 8.9 M (29.2 FT) SOUTH OF THE CENTER OF THE ROAD, 1.3 M (4.3 FT) EAST OF THE NORTHEAST CORNER OF A CATCH BASIN, LEVEL WITH THE ROAD, AND IN A CONCRETE MONUMENT THAT IS FLUSH WITH AND SURROUNDED BY A SIDEWALK.
IN LONG BEACH, AT THE INTERSECTION OF WARDLOW ROAD AND CHERRY AVENUE, 13.9 M (45.6 FT) WEST OF THE CENTERLINE OF THE SOUTHBOUND LANES OF THE AVENUE, 4.0 M (13.1 FT) SOUTH OF THE CENTERLINE OF THE EASTBOUND LANES OF THE ROAD, 3.6 M (11.8 FT) NORTHWEST OF A SIGNAL LIGHT POLE, 1.2 M (3.9 FT) EAST OF THE NORTHEAST CORNER OF A CATCH BASIN, 0.2 M (0.7 FT) ABOVE THE LEVEL OF THE ROAD, AND THE MONUMENT IS FLUSH WITH A SIDEWALK.
March 1996 Caltrans Inspection: No visible damage

PID: AA3228 Residual = -9.2 cm Type N
NAME: 5 43
3.0 KM (1.85 MI) SOUTHERLY ALONG INTERSTATE HIGHWAY 5 FROM THE JUNCTION OF STATE HIGHWAY 14 IN SAN FERNANDO, NEAR THE NORTH CORNER OF A CONCRETE CATCH BASIN, 7.6 M (24.9 FT) NORTH OF STREET LIGHT POLE NUMBER 43761, 5.4 M (17.7 FT) SOUTHWEST OF THE FOG LINE OF THE SOUTHBOUND HIGHWAY, 3.4 M (11.2 FT) NORTHEAST OF CALL BOX NUMBER 439, AND 0.2 M (0.7 FT) BELOW THE LEVEL OF THE HIGHWAY.
March 1996 Caltrans Inspection: No visible damage.

PID: AA3231 Residual = -11.9 cm Type C
NAME: 5 42.1
5.8 KM (3.60 MI) SOUTHERLY ALONG INTERSTATE HIGHWAY 5 FROM THE JUNCTION OF STATE HIGHWAY 14 IN SAN FERNANDO, NEAR THE SOUTH CORNER OF THE MOST NORTHWESTERLY OF 3 CONCRETE CATCH BASINS, 12.7 M (41.7 FT) SOUTH OF CALL BOX NUMBER 419 T, 11.0 M (36.1 FT) SOUTHWEST OF THE FOG LINE OF THE

SOUTHBOUND AUTOMOBILE LANES OF THE HIGHWAY, 3.0 M (9.8 FT) SOUTHWEST OF THE FOG LINE OF THE SOUTHBOUND TRUCK LANES OF THE HIGHWAY, 1.6 M (5.2 FT) NORTHEAST OF A WITNESS POST, AND 0.2 M (0.7 FT) SOUTHWEST OF A CURB.
March 1996 Caltrans Inspection: Small cracks in pavement.

PID: AA3234 Residual = -11.9 cm Type N
NAME: 405 47.2
IN MISSION HILLS, AT THE INTERSECTION OF FREEWAY 405 AND SAN FERNANDO MISSION BOULEVARD, NEAR THE SOUTHEAST CORNER OF THE CONCRETE FOUNDATION OF 2 UNDERGROUND CABLE JUNCTION BOXES, 68.0 M (223.1 FT) NORTH OF CALL BOX NUMBER 473, 28.5 M (93.5 FT) SOUTH OF THE CENTER OF THE BOULEVARD, 4.8 M (15.7 FT) WEST OF THE FOG LINE OF THE SOUTHBOUND FREEWAY, 0.4 M (1.3 FT) SOUTHWEST OF THE WEST END OF THE SOUTH ABUTMENT OF THE FREEWAY OVERPASS OF THE BOULEVARD, AND 0.2 M (0.7 FT) ABOVE THE LEVEL OF THE FREEWAY.
March 1996 Caltrans Inspection: No visible damage.

PID: AA3236 Residual = -10.4 cm Type N
NAME: 405 46.1
IN MISSION HILLS, AT THE INTERSECTION OF FREEWAY 405 AND DEVONSHIRE STREET, NEAR THE NORTHWEST CORNER OF A CONCRETE CATCH BASIN, 230.0 M (754.6 FT) SOUTH OF THE CENTER OF THE STREET, 49.0 M (160.8 FT) NORTH OF THE SOUTH END OF THE MEDIAN BETWEEN THE SOUTHBOUND FREEWAY AND FREEWAY ON-RAMP FROM THE STREET, 2.4 M (7.9 FT) WEST OF THE FREEWAY FOG LINE, 1.4 M (4.6 FT) EAST OF A WITNESS POST, AND 0.2 M (0.7 FT) BELOW THE LEVEL OF THE FREEWAY.
March 1996 Caltrans Inspection: No visible damage.

PID: EW4844 Residual = -13.9 Type N
NAME: 04 05510
AT LOS ANGELES. WIRE SPIKE IN THE WEST CURB OF BALBOA BOULEVARD, 3 FEET NORTH OF THE BEGINNING OF CURB RETURN NORTH OF INDEX STREET. IN GRANADA HILLS, AT THE INTERSECTION OF BALBOA BOULEVARD AND INDEX STREET, A SPIKE IN THE WEST CONCRETE CURB OF THE BOULEVARD, 14.8 M (48.6 FT) NORTH OF THE CENTER OF THE STREET, 7.1 M (23.3 FT) WEST OF AND LEVEL WITH THE CENTERLINE OF THE SOUTHBOUND LANES OF THE BOULEVARD, 3.1 M (10.2 FT) EAST OF A ROCK COLUMN, AND 1.0 M (3.3 FT) NORTH OF THE SOUTH END OF THE BEGINNING OF THE CURB RETURN NORTH.

PID: AA3256 Residual = 4.1 cm Type C
NAME: 405 40.2
IN SHERMAN OAKS, AT THE INTERSECTION OF FREEWAY 405 AND BURBANK BOULEVARD, 138.5 M (454.4 FT) SOUTH OF THE CENTER OF THE BOULEVARD, 15.3 M (50.2 FT) NORTH-NORTHWEST OF A SIGN (EXIT ARROW) , 15.3 M (50.2 FT) NORTH OF THE NORTH END OF THE SHOULDER BETWEEN THE SOUTHBOUND FREEWAY AND THE OFF-RAMP LEADING TO THE BOULEVARD, 12.3 M (40.4 FT) NORTH-NORTHWEST OF A SIGN (EXIT ARROW) , 11.8 M (38.7 FT) WEST OF THE CENTER OF THE RAMP, 3.1 M (10.2 FT) EAST OF THE FREEWAY FOG LINE, 0.8 M (2.6 FT) WEST OF A WITNESS POST, 0.3 M (1.0 FT) WEST OF THE EAST EDGE OF SHOULDER, DISK ON TOP OF A 0.9 METER LONG PIPE SURROUNDED BY AND RECESSED 0.01 M (0.03 FT) BELOW LEVEL OF SHOULDER.
March 1996 Caltrans Inspection: No visible damage.

APPENDIX II

Appendix II. GPS stations measured by the California Department of Transportation (Caltrans) as part of the post-Northridge survey.

Co-Seismic Displacements of the 1994 Northridge, California, Earthquake

by K. W. Hudnut, Z. Shen, M. Murray, S. McClusky, R. King, T. Herring, B. Hager,
Y. Feng, P. Fang, A. Donnellan, and Y. Bock

Abstract The 17 January 1994 Northridge, California, earthquake significantly deformed the Earth's crust in the epicentral region. Displacements of 66 survey stations determined from Global Positioning System (GPS) observations collected before and after the earthquake show that individual stations were uplifted by up to 417 ± 5 mm and displaced horizontally by up to 216 ± 3 mm. Using these displacements, we estimate parameters of a uniform-slip model. Fault geometry and slip are estimated independent of seismological information, using Monte Carlo optimization techniques that minimize the model residuals. The plane that best fits the geodetic data lies 1 to 2 km above the plane indicated by aftershock seismicity. Modeling for distributed slip on a coplanar, yet larger model fault indicates that a high-slip patch occurred up-dip and northwest of the mainshock hypocenter and that less than 1 m of slip occurred in the uppermost 5 km of the crust. This finding is consistent with the lack of clear surface rupture and with the notion that the intersection with the fault that ruptured in 1971 formed the up-dip terminus of slip in the Northridge earthquake. Displacements predicted by either of these simple models explain most of the variance in the data within 50 km of the epicenter. On average, however, the scatter of the residuals is twice the data uncertainties, and in some areas, there is significant systematic misfit to either model. The co-seismic contributions of aftershocks are insufficient to explain this mismatch, indicating that the source geometry is more complicated than a single rectangular plane.

Introduction

The M_w = 6.7 17 January 1994 Northridge earthquake (USGS and SCEC, 1994) produced measurable co-seismic displacements over a large area (approximately 4000 km²) including much of the San Fernando Valley and adjacent mountainous areas. Over the region of largest slip on the fault plane, the Earth's surface was pressed into an asymmetric dome-shaped uplift, skewed toward the NNE. Over the uplifted region, the largest horizontal displacements also occurred, with displacement outward from the apex of the dome. The significant NNE-oriented shortening at the NNE and SSW margins of the domed area indicate the net compression that occurred between the hanging wall and footwall of the thrust fault that ruptured.

We have used Global Positioning System (GPS) geodetic data to quantify the static displacement field associated with the earthquake and its aftershocks. In this study, we sampled the displacement field at 66 stations (documented in Tables 1 and A1) with GPS-derived vectors measured with 1-sigma errors ranging 3 to 42 mm (east–west), 3 to 25 mm (north–south), and 3 to 90 mm (vertical). Our estimates are based on station positions measured within 15 months prior to and 1 month following the earthquake. In our analysis, we corrected for secular velocities at all of the stations by spatially interpolating between velocities estimated previously for 15 stations, using measurements spanning 5 or more years.

From the set of co-seismic displacement vectors we determined, we modeled the earthquake source using previously established methods based on the elastic dislocation theory. First, we estimated the dislocation source that could best explain the geodetic data with a single uniform-slip dislocation following the nonlinear optimization approach of Murray *et al.* (1994) and using a single rectangular dislocation in a homogeneous half-space. We then estimated the spatial distribution of slip on a larger (yet coplanar) fault surface following the singular value decomposition inversion approach implemented by Larsen (1991). This modeling is secondary to the data portions of this article and should be viewed in the context of other studies of the earthquake's source (Wald and Heaton, 1994b; Dreger, 1994; Shen *et al.*, this issue; Wald *et al.*, this issue). The models presented here interpret these GPS data independent of other information. Wald *et al.* (this issue) combine these GPS results with other data to estimate a more comprehensive source model.

Table 1

GPS Displacements and Model Residuals (displacements and residuals are in millimeters; errors are 1-sigma; component and vector "nres" values are normalized residuals)

Note: For this analysis, the global stations ALGO, FAIR, KOKB, MADR, HART, YELL, YAR1, KOSG, TROM, WETT, SANT, TIDB, and DS1B were constrained to their ITRF'93 positions.

Data and Analysis

The GPS data used for our analysis were obtained in field surveys between October 1992 and February 1994 and from continuous observations at stations of the southern California permanent GPS geodetic array (PGGA) (Bock, 1993b) and the global tracking network overseen by the International GPS Service for Geodynamics (IGS) (Beutler and Brockmann, 1993). The accuracy with which a station's position can be estimated from each field survey is generally 5 to 15 mm for the horizontal coordinates and 10 to 30 mm for height (see Table 1, error columns), depending primarily on the number of days that station was observed and the length of each observation session. Most of the pre-earthquake and postearthquake data are from four distinct field projects, each of which has a different history of observations that is documented in Table A2 and Figure A1. A total of 534 occupations of 66 survey stations were made during 92 field sessions. These data were combined with global and regional continuously recorded GPS data covering 24 hours on the day of each field session.

We analyzed the data in two steps. In the first step, we used the GPS phase and pseudorange measurements to estimate station coordinates, satellite orbital parameters, and atmospheric delay corrections for each day of observation. For this step, we loosely constrained the coordinates and velocities of regional and global stations. In the second step, we combined the estimates and their covariance matrices from all of the days, applying position and velocity constraints to 13 globally distributed stations (listed in Table 1) to obtain a consistent solution for displacements at the epoch of the earthquake. For all of the experiments, we resolved integer-cycle ambiguities in the phase observations using the iterative technique described by Feigl *et al.* (1993). The two-step approach allowed us to distribute both the processing of the raw GPS observations and the combination of solutions among several groups, encouraging redundant and progressively improved analyses (see Table A2).

Figures 1 and 2 and Table 1 show our estimates of displacements for 66 GPS monuments within about 75 km of the Northridge epicenter. The uncertainties given in Table 1 and plotted in Figures 1 and 2 represent our best estimate of the 1-sigma error for each value or vector. These cannot be rigorously computed from the uncertainty in the GPS phase measurements because the error spectrum of these measurements is poorly understood. Rather, they are based on studies of short- and long-term repeatabilities for a subset of station position estimates from this analysis and the set for southern California between 1986 and 1992 (Feigl *et al.*, 1993). These studies suggest that for short observation sessions (<5 hr), the formal uncertainties are roughly consistent with long-term repeatability; for longer single-day sessions (5 to 8 hr), the formal uncertainties should be increased by a factor of 2 to 3; and for sessions of 24 hr or more, the appropriate scale factor is 3 to 4. Since the present analysis includes data from observation sessions ranging from 2 to 24 hr, a simple scaling of the formal uncertainties to achieve a chi-square of unity for the long-term scatter of estimates is inappropriate. The simplest approach, which we have adopted, is to add a constant value ([3 mm]^2) to the variance estimated for each coordinate in the solution.

We are able to check the validity of our weighting by examining the estimated displacements of stations sufficiently far from the epicenter that we expect small errors in their modeled displacements. If we adopt the arbitrary criteria that these stations should have model-predicted displacements less than 10 mm in all components, and estimated uncertainties less than 10 mm in the horizontal and 40 mm in the vertical components, then 12 stations are available for analysis. One of these stations, HOPP, has a 4-sigma residual in its east component (-13 ± 3 mm), a result that may be related to unmodeled motion on a second fault plane (discussed below). A second station, PEAR, has a 5-sigma residual in the east (16 ± 3 mm) that is not yet understood. For the remaining 10 stations (whose names are italicized in Table 1), the values of the square root of the reduced chi-square (nrms) for the east, north, and vertical residuals are 1.5, 1.0, and 1.2, respectively. From this we conclude that the uncertainties given in Table 1 are reasonable estimates of the 1-sigma errors for most stations.

Another concern arises from the small number of independent measurements for many stations (Fig. A1). For monuments with only one or two measurements in either the period before or after the earthquake, there is significant chance of undetected error. Such an error could arise in either the observations (e.g., by receiver malfunction, by improperly positioning the antenna over the survey monument, or by mis-measuring the antenna height) or the analysis (e.g., improperly repairing cycle slips).

All pre-earthquake data we used were collected within 15 months of the earthquake. Since the relative interseismic motions of most of the stations are small or well known, there is little error introduced by mismodeling these motions. The assumed velocities for the stations involved in this study (Table A1) were interpolated using 15 well-determined secular velocities and a simple model for slip on the San Andreas fault system (Feigl *et al.*, 1993). We believe that the velocity errors for the stations we used are less than 3 mm/yr.

Modeling

We used two methods to model the measured displacements. First, we applied an extension of the Monte Carlo technique following Murray *et al.* (1994), an approach that is well suited to finding the single-dislocation model that best fits the geodetic data and that is independent of seismological and geological information. To the extent that the inherent simplifying assumptions are valid, the result of this method points out that the geodetic data are best fit by slip on a plane that lies 1 to 2 km above the aftershock plane, northwest and up-dip of the mainshock hypocenter. Second, by inversion of the displacement data, we estimated variable

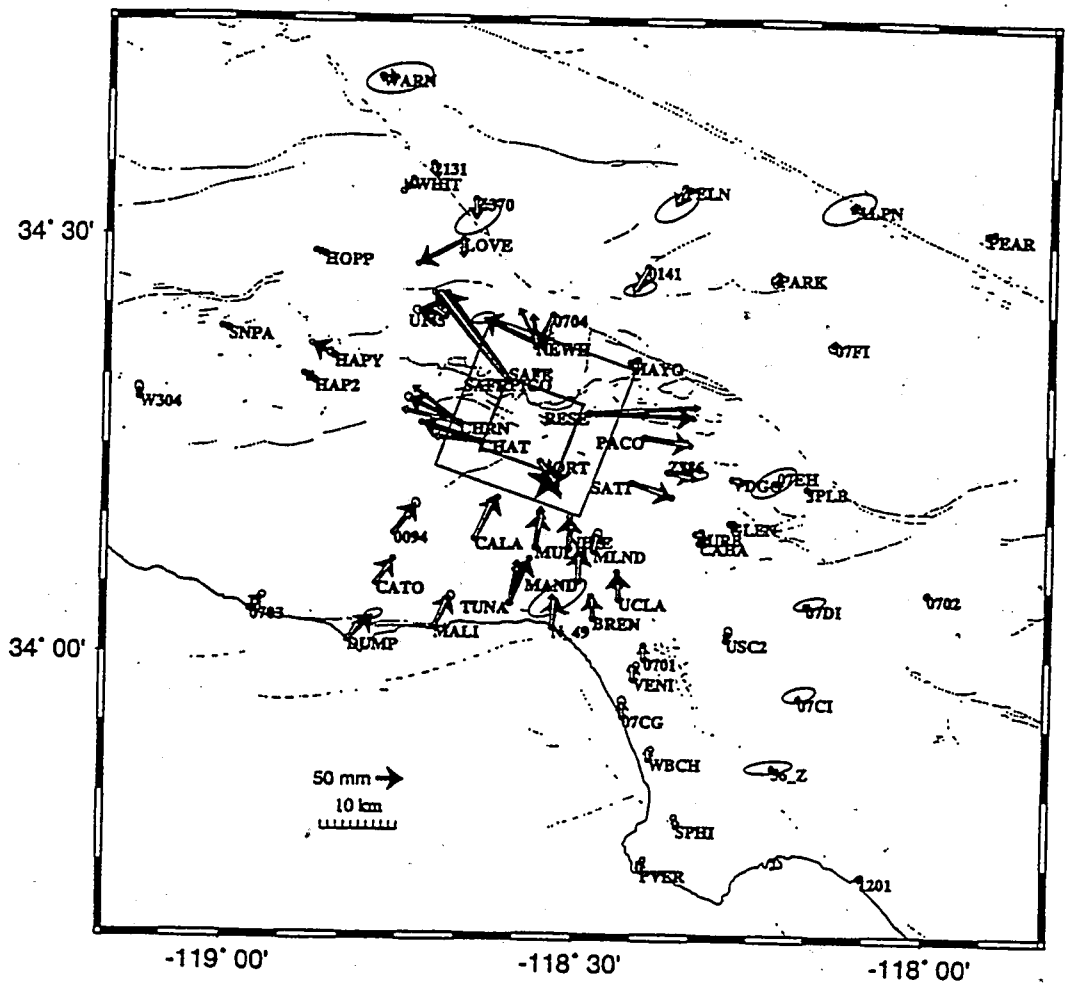

Figure 1. Measured displacements associated with the Northridge earthquake. Station locations are indicated by gray circles (and identified by a 4-character I.D. for reference to the tables). Horizontal displacement is shown by a heavy black vector and corresponding 1-sigma ellipse. Uniform-slip model vectors are shown in white; variable slip model is shown in gray.

slip on an enlarged and coplanar model fault plane. Neither approach led to statistically adequate fits to the GPS data, yet we limited ourselves to this class of models for the sake of simplicity. Also, because we had no unambiguous, objective basis to discard outliers, all of the GPS measurements were included in both modeling approaches, despite our recognition that certain stations clearly could not be fit well with these simple source models.

Both approaches are based on the elastic dislocation theory, which can be used to compute the displacements at a given point on the ground surface from a slip distribution model (e.g., Steketee, 1958; Chinnery, 1961; Savage and Hastie, 1966; Mansinha and Smylie, 1971; Okada, 1985). Both our forward and inverse modeling approaches incorporated a combination of algorithms from these references. The model geometry is displayed in Figures 1, 2 and 3, where we indicate the map view and cross-section geometry of the model fault surfaces. Modeled displacements are shown in Figures 1 and 2, and the residuals between the observations and each of the two models are given in Table 1 and Figure 7.

Nonlinear Optimization Method

We first estimated the best model with uniform slip on a single rectangular fault. This simple model is described by nine parameters that give the location, orientation, and dimensions of the dislocation plane, as well as the slip vector on that plane (see Table 2). We used nonlinear optimization methods, based on extensions of the Monte Carlo technique, to randomly vary the fault geometry and estimate the slip vector until the model with the smallest sum-squared residuals (χ^2) was found. This method provides a fault model that, on average, shows where the slip is concentrated at depth, but the assumption of uniform slip on a simple rectangle is clearly an oversimplification of the actual slip distribution.

We used the following procedures and assumptions,

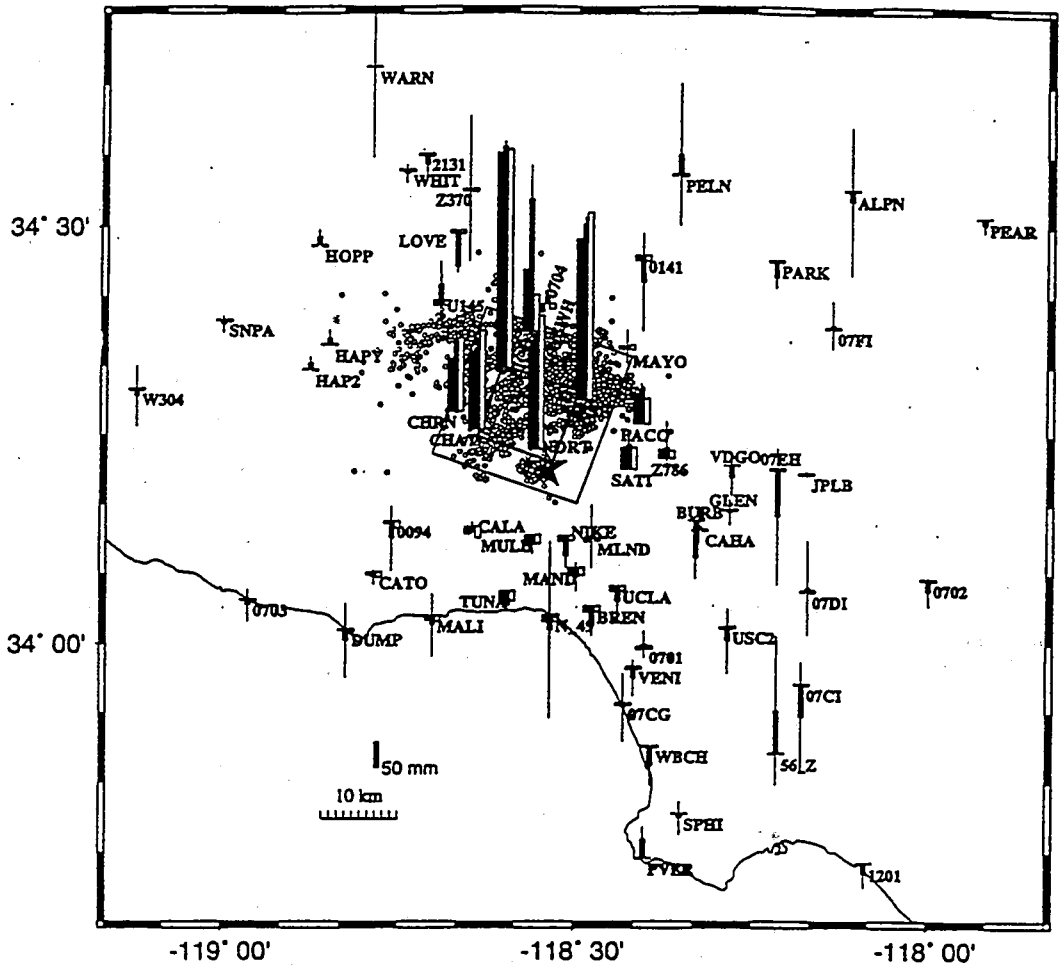

Figure 2. Measured and modeled vertical displacements at the GPS stations. Measured vertical displacements are shown by the central black column at each station, and the 1-sigma error is indicated by a vertical line. Uniform-slip model columns are shown in white; variable slip model is shown in gray.

Table 2
Model Parameters for Optimal Single-Dislocation Source Model and Its 95% Confidence Limits

Parameter	Optimal Model	95% Range	
		Low	High
Strike (deg)	109.56	100.53	118.77
Dip (deg)	40.96	38.17	43.65
Width (km)	13.28	9.35	17.12
Length (km)	10.51	6.28	13.11
Centroid depth (km)	10.07	9.00	11.34
Centroid latitude (deg)	34.2753	34.2647	34.2834
Centroid longitude (deg)	−118.5674	−118.5605	−118.5762
Slip magnitude (m)	2.50	1.91	4.40
Slip rake (deg)	91.3	84.1	97.2
Moment (N-m)	1.05×10^{19}	0.93×10^{19}	1.19×10^{19}

based on Murray *et al.* (1994). Slip was assumed to be uniform on a single rectangular fault, with its top edge parallel to the Earth's surface and embedded in a homogeneous isotropic elastic half-space with rigidity = 30 GPa. The projection was polyconic, with east-north correlations neglected. While the modeling procedure could be improved mathematically by including the correlations, which are available from the GPS data analysis (Table 1), such a change would be unlikely to cause substantive changes in our results.

For the optimal model, $\chi^2 = 2082$ (with 198 data and estimating nine parameters), yielding an nrms residual of 3.32. To assess uncertainties in the model, we compared trial models to the optimal model using an F-ratio test (Draper and Smith, 1981). Table 2 gives the parameters for the optimal model (and its 95% confidence limits), and Table 1 and Figure 6 show the distribution of normalized residual values. We believe that the large nrms residual results primarily from using too simple a model and not necessarily from an underestimate of uncertainties in the displacements,

as discussed below. Nevertheless, this model explains 95% of the variance in the GPS data (for the null model, i.e., no deformation, $\chi^2 = 41{,}600$).

The plane estimated by this approach dips toward the SSW and indicates that the main slip concentration occurred up-dip and toward the northwest of the mainshock hypocenter. This plane is evidently not coplanar with the aftershocks. Figure 3 shows the model plane plotted in cross section with respect to relocated aftershocks from Mori *et al.* (1995). The model plane is nearly parallel to the seismicity plane, lying 1 to 2 km above it. At the hypocenter, the vertical distance from the hypocenter to the (projected) model plane is about 2 km, considerably greater than the stated error in hypocentral depth of 0.4 km. One possible explanation that has not yet been evaluated is that the hypocenter determination and GPS-based modeling approaches have different datums, causing a shift in apparent depth that is due mainly to differences in methods. However, it seems highly unlikely that so large a shift could occur from that alone. More importantly, our assumption of a uniform Poisson solid for the physical model may introduce inaccuracy. A similar discrepancy has been observed and discussed elsewhere (e.g., Ekstrom *et al.*, 1992; Stein and Ekstrom, 1992), in which case it was attributed to assuming a half-space in the presence of variable crustal rigidity surrounding the modeled fault. This possibility is also noted by Shen *et al.* (this issue) and treated in more detail there.

Singular Value Decomposition Inversion Method

To solve for the slip distribution on an assumed fault plane, we applied singular value decomposition (SVD) (e.g., Jackson, 1972; Menke, 1989). SVD is a matrix decomposition technique used to estimate parameters when the model space is poorly constrained by the data. This approach is often used in geodetic inversions for fault slip, since the data must be obtained at the surface and, therefore, poorly resolve slip at depth (Harris and Segall, 1987; Segall and Harris, 1987; Freymueller *et al.*, 1994; Hudnut and Larsen, 1993). The technique is equivalent to least squares when the number of singular values equals the number of unknown parameters. Using a lower number of singular values means that only those parts of the model that are well mapped by the data will be estimated.

This modeling approach assumes a fault geometry. We assumed the model fault to be coplanar with that estimated by our nonlinear optimization approach (Fig. 3). We roughly doubled the length and width dimensions and extended the model plane up-dip; we used the strike, dip, and location of the optimal plane (Table 2). We assumed the fault plane to be 20 by 26 km and specified it to be composed of 130 subfaults, each 2 by 2 km. The model fault plane extends to within 1 km of the ground surface, and the center point of this plane is located at a depth of 9.86 km. We inverted the GPS estimates of displacement vector components and their associated errors (from Table 1) to estimate the thrust and strike-slip components of slip on each subfault, as described by Larsen (1991) and Hudnut and Larsen (1993). The number of parameters estimated was 260, and the number of data was 198 (each displacement vector contains three components).

We employed no positivity or slip constraints, nor smoothing apart from that which occurs inherently in the SVD method of inversion. In SVD, when the eigenvalue matrix is truncated, a form of smoothing is implemented. In this case, the number of singular values chosen was 23, because this solution was within the range of most reasonable solu-

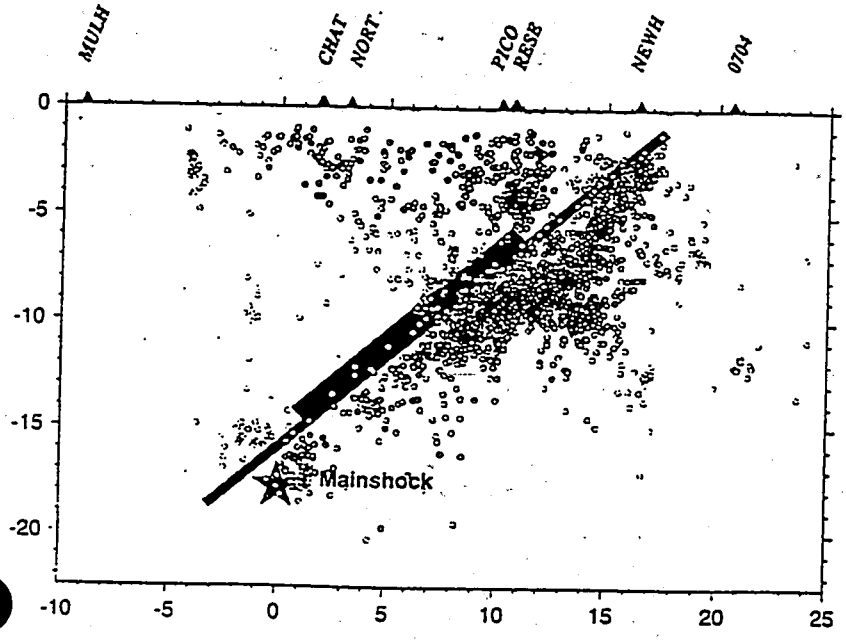

Figure 3. Cross section showing the model fault planes overlain on the aftershocks relocated by Mori *et al.* (1995). We find that one cannot model the geodetic data as well when assuming the fault plane is coplanar with the aftershocks. The uniform slip model plane is shown as a thick gray line, and the larger coplanar fault assumed for the variable slip model is shown as a thinner black line.

tions, obtaining a total moment of 1.63×10^{19} N-m and fitting the GPS data relatively well ($\chi^2 = 1681$). Other solutions at higher and lower singular values yielded qualitatively similar slip distributions in the range $18 < k < 25$, where k is the number of singular values. Within this "stable" range, the total moment increased from 1.55 to 1.71×10^{19} N-m, and the data nrms decreased slightly. Although a more rigorous selection of the optimal result from this approach is possible using an F-test (Jacobsen and Shaw, 1991), we made our selection by inspection. It is valid, yet somewhat subjective, to select the number of singular values retained in this manner (e.g., Parker, 1977). Figure 4 shows the changes in key parameters with increasing number of singular values, allowing our selection to be evaluated. The additional parameter shown (subfault nrms) indicates dispersion in the amount of slip on each subfault.

As expected, the variable slip model does fit the data better than the uniform slip model, with a 40% reduction in variance. For this variable slip model (Fig. 5), we effectively estimated 23 parameters, whereas the uniform slip model has only 9. Taking this into account, we still find that the variable slip model (nrms = 3.10) fits the data better than does the uniform slip model (nrms = 3.32). Both models explain 95% or more of the variance, but neither provides a statistically satisfactory fit to the data. Using a less stringent norm, say by doubling all of the stated errors, one could claim that either model fits the data adequately, but we do not feel this would do justice to the problem. In one test, we doubled the stated vertical errors (but kept the horizontal errors the same) and reran the variable slip model. The result of this test, however, was a barely reduced total nrms within the "stable" range of singular values, at the expense of a considerably higher total moment and subfault nrms. That is, loosening the error constraints made the model less physically reasonable. For these reasons, we feel this issue requires discussion, as there are many possible sources of the misfit, and simply doubling the stated errors would not explain the recognized and suspected problems.

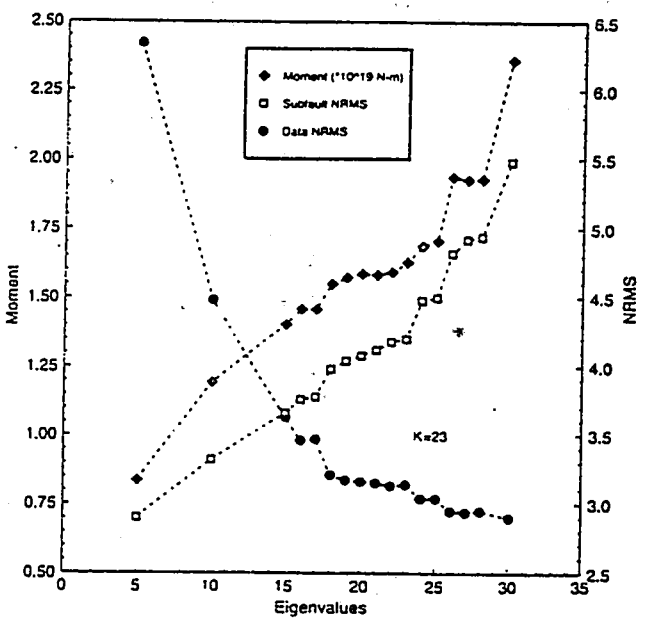

Figure 4. Total moment, subfault nrms, and data nrms (both based on reduced chi-squared values) as a function of the number of retained consecutive eigenvalues for the variable slip modeling. The total moment uses the length of each subfault's slip vector, summed over all subfaults. The subfault nrms is an index of dispersion for the length of all subfaults' slip vectors. The data nrms is a similar index for the model residuals.

Discussion

The normalized residuals between the data and either proposed model (Table 1 and Fig. 6) are greater than ex-

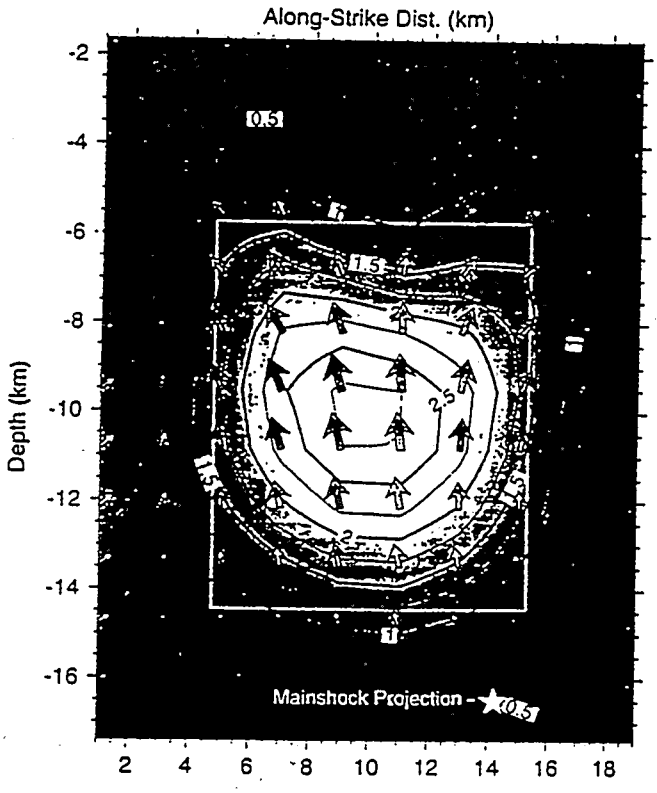

Figure 5. Distribution of slip on the Northridge fault plane. Contours and shading indicate the slip amplitude (in meters), and arrows indicate the slip vector for each subfault of the model. The model has 10 subfaults along-strike and 13 down-dip, each 2 by 2 km. Slip evidently occurred mainly up-dip and northwest of the hypocenter. Less than 1 m of slip occurred above a depth of 5 km. This model, based solely on the GPS data, differs substantially from those based solely on seismological data (Wald and Heaton, 1994b; Dreger, 1994). It differs, but less dramatically, with the "geodetic only" and "combined" models of Wald *et al.* (this issue).

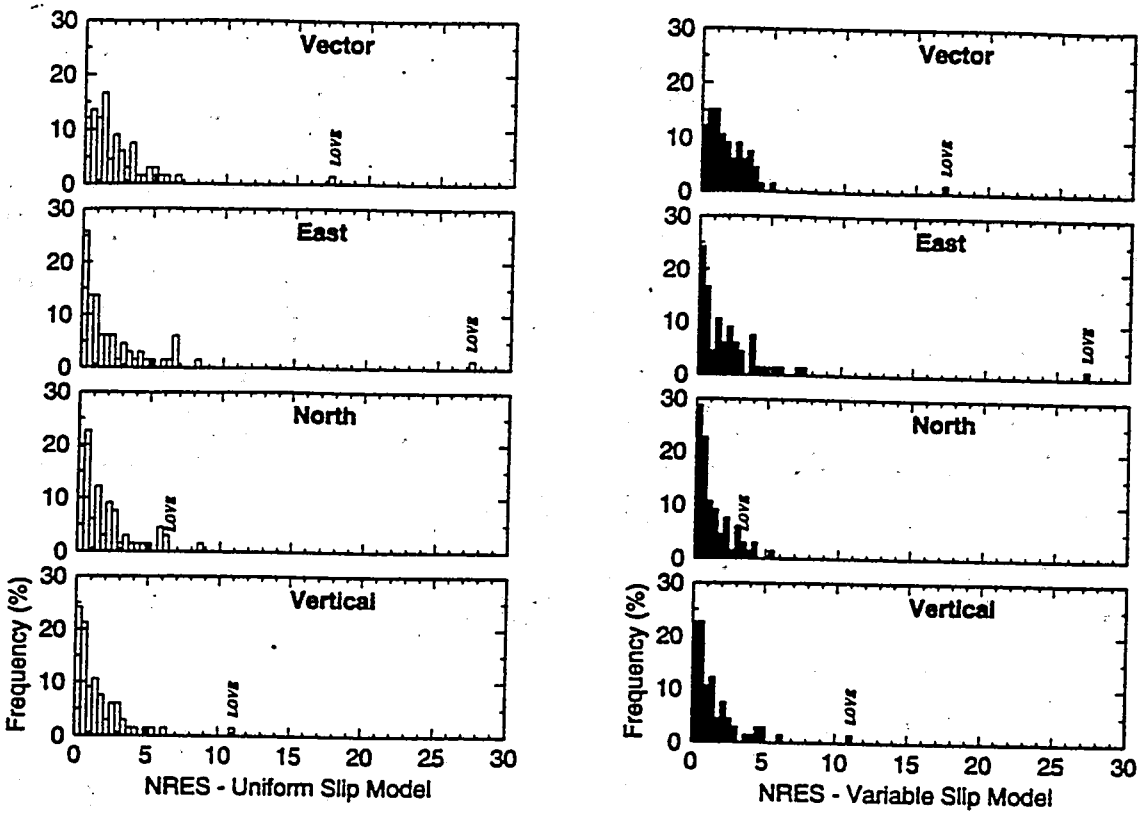

Figure 6. Distribution of normalized residual (NRES) values for the uniform and variable slip models. The outlier (especially in the east and vertical components) is station LOVE, whose displacement is anomalous (as discussed in the text).

pected (as is the summary nrms statistic for each model). This could be due in part to underestimating the measurement uncertainties, lack of an error model component representing monument instability, a poor physical model (i.e., neglecting the complexities of crustal structure and irregularities of the surfaces that ruptured, and the contributions of aftershocks), or data outliers (i.e., measurement blunders). Both modeling approaches have most difficulty fitting the same few stations, which are located within the same general area, so an inadequate physical model seems a likely explanation. However, the affects of aftershocks and monument instability may also be important for some stations.

Aftershocks. The displacement field contributions of aftershocks that occurred soon after the mainshock are, by necessity, included in our GPS data. Relatively shallow aftershocks, especially with $M > 5$, may have contributed to the displacement field we measured. For example, about 1 min after the mainshock, a shallow $M = 5.9$ aftershock occurred, and within 10 min, another shallow $M = 5.2$ occurred (according to the Caltech/USGS catalog based on Southern California Seismic Network data). Because these two events occurred so early after the mainshock, their locations and especially their depths are not well known. Hence, it is not possible to confidently model their contributions to the displacement field based solely on seismological information. In the preceding modeling section, we made no attempt to remove the effects of these two aftershocks, so what we call "co-seismic" actually includes these two early aftershocks. In that sense, our data differ from the seismological data used by Wald and Heaton (1994b) or Dreger (1994) to arrive at slip distribution models. Wald *et al.* (this issue) evaluate and discuss this issue.

Subsequent to these two early aftershocks, all other $M > 5$ aftershocks occurred between depths of 9 and 20 km, except for the shallow $M = 5.1$ event on 29 January. Displacement estimates given for the three GPS stations on Oat Mountain, PICO, SAFE, and SAFR are from data collected prior to the 29 January aftershock, and other GPS stations were unlikely to have been perturbed by that event. Over 40 aftershocks with $M > 4$ occurred within the first two weeks, many of which were shallow.

Monument Instability. Some errors may arise from infidelity of our survey monuments in representing tectonic signals. Although long-term monument stability is a serious issue for studies of interseismic motion, over the 16-month period of our observations, its effects are likely at the level of only a few millimeters (Langbein *et al.*, 1993a, 1993b; Wyatt, 1982; Johnson and Wyatt, 1994). More serious is the pos-

sibility that the strong shaking some of these monuments experienced during the Northridge earthquake may have created local displacements that are not representative of the upper crust.

Practices of surveying monument construction vary, as does the type of material in which monuments are emplaced. The simplest type of monument, several of which are used in this study, consists of a metal disk set with concrete into a drill hole in bedrock. Another common type consists of a concrete mass poured into a shallow hole that has been excavated in the soft rock or soil, with a metal disk at the top. Each of the older monuments used is one of these two types. More recently, for example, when Caltrans and NGS established the high precision geodetic network (HPGN) and HPGN-densification (HPGN-D) networks in the early 1990s, monuments called 3D rod marks were set in soft rock or soil. These marks are now preferred over the concrete mass type since they are not coupled to the uppermost soil and provide a deeper point of attachment to the ground. Still other monuments, of which there are few, are installed by attaching a metal disk to existing masonry such as retaining walls.

Because we typically have measured only one geodetic station at each location in our network, the contribution of monument instability to our errors is difficult to quantify. We have only one site (Oat Mountain) where coincidentally we had three separate monuments for which we obtained both pre- and postseismic GPS data of good quality. Also coincidentally, this site is the location of the largest displacements measured with GPS and presumably where ground shaking was very strong. The three Oat Mountain monuments (PICO, SAFE, and SAFR) are all set in soft, highly fractured rock capped with a thin (<0.5 m) veneer of soil. During the earthquake, these monuments likely experienced 0.5 to 1.0 g accelerations and 0.5 to 1.0 m/sec velocities. Monuments SAFE and SAFR are concrete masses with metal disks. From visual inspection before and after the earthquake, we concluded that SAFE was the better of the two because soil around the base of the concrete mass for SAFR had eroded away. PICO is a metal disk attached to a metal rod that was driven into the ground "to refusal" with a sledge hammer, and hence, it is probably less susceptible to surficial movements than either SAFE or SAFR. In Table 1, the results for motion of PICO, SAFE, and SAFR are given. The displacements estimated for these three sites disagree by up to 25 mm in the east component, up to 2 mm in the north component, and up to 28 mm in the vertical component. The differences in east and vertical displacements are outside our estimated 1-sigma measurement errors. These discrepancies occur between PICO and SAFE, the stations with better data. PICO was observed twice before and nine times after the earthquake, while SAFE was observed 10 times before and three times after (Fig. A1). SAFR has just one measurement each before and after the earthquake and is therefore suspect on geodetic grounds. We do not understand the discrepancy between our measurements at Oat Mountain, but we tentatively attribute them to localized monument instability induced by ground shaking in the earthquake. For this article, we have included the displacement estimates for PICO, SAFE, and SAFR in our modeling.

For another station, NORT, we had different concerns. The station is located about 3 km NNW of the mainshock epicenter; hence, its observed southeastward displacement is counterintuitive. The displacement was primarily vertical, with uplift of 213 ± 8 mm and horizontal motion of 68 ± 3 mm. This monument, an HPGN-D station, is a metal disk set in a poured concrete wall along a train track and flood control channel. The earthquake caused a train to derail adjacent to this station, and during the first occupations of this station after the event, we observed heavy equipment moving past the monument, within 1 m of the base of the wall. The equipment, which was being used to clear the train wreck from the tracks, compacted the asphalt road bed on the south side of the wall. When we arrived at the station, we observed a new crack in the wall (<10-mm movement), about 5 m southeast of the monument. The situation of the monument in such a wall, the crack that indicated damage to the structure, and the compaction of soil on the south side of the wall gave rise to concerns about monument instability. This monument was geodetically leveled before and after the earthquake relative to other benchmarks in the NGS/Caltrans vertical control network, and from this leveling, it appears that NORT went up by an amount similar to nearby benchmarks. We have no way to independently ascertain the horizontal integrity of the monument, except to say that by visual inspection, the wall appears to still be in line with the extension of the wall to the NW, and not to be tilted. In one test of the uniform slip model, the displacement of station NORT was left out without substantively changing the model results.

The station we have most difficulty fitting within errors is LOVE (Figs. 6 and 7). This station's displacement is very well determined, but the monument is a mass of concrete set in soft rock and soil. One possibility is that the motion of this monument included nontectonic motion induced by shaking since it also is located where strong ground motions occurred. There was a landslide and considerable ground cracking downhill from the site, but no cracks were observed north (uphill) of the site. A minor crack was observed to run in the soil through the monument. Although the assessment of those who visited the site was that the monument was probably not disturbed by more than 10 to 20 mm, the potential for significant nontectonic motion should not be overlooked.

The horizontal residual for NEWH is similar to that of LOVE, yet NEWH's residual is up (150 to 180 mm), whereas LOVE's residual is down (60 mm). Of course, since NEWH's displacement is less accurately determined, the modeling approaches we used would tend to allow its residual to be large. That is why we focus more on LOVE as the outlier station, even though the absolute residuals at NEWH are larger. The monument at NEWH is a concrete mass set in soil. Both NEWH and 0704 are very close to the up-dip displacement

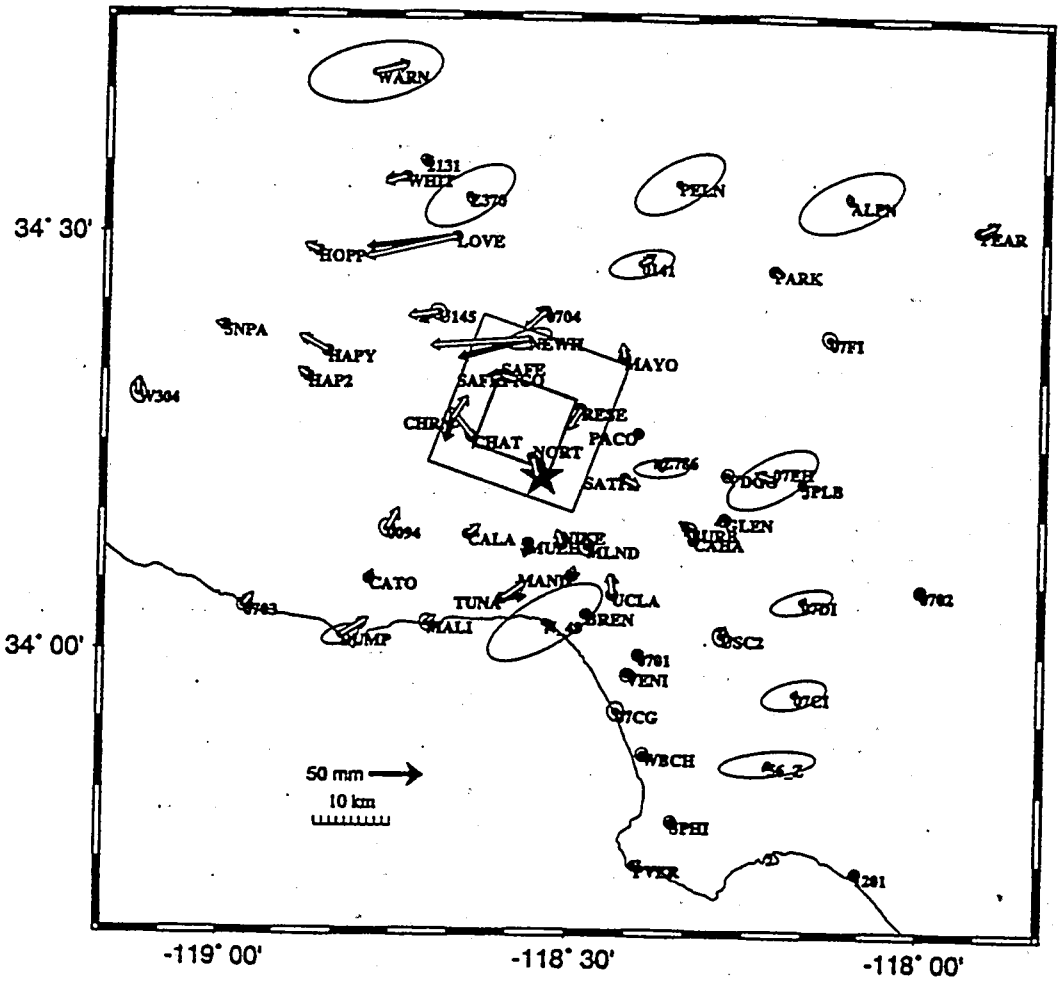

Figure 7. Residual vectors at the GPS stations. Some spatial systematics appear to remain in these unmodeled data, particularly in the vicinity of the eastern Ventura Basin, as discussed in the text. Also, residuals are significant but diversely oriented in the Santa Monica Mountains (near the down-dip edge of the rupture). Note the vector scale is several times larger than in Figure 1.

node, and we suspect that the misfits at these two stations may indicate some unmodeled slip on shallow structures (perhaps in combination with other potential problems we have mentioned). Aftershock seismicity indicates a steeper-dipping up-dip extension of the main rupture plane that would project to a line between these two stations, for example. Alternatively, the misfits could be explained by some sympathetic slip on hanging-wall structures.

Other stations in the vicinity of LOVE and NEWH (0704, CHAT, HAPY, HOPP, U145, and WHIT) are misfit less drastically, yet with a somewhat consistent westward component in the residual vectors (Fig. 7). Furthermore, preliminary results from leveling along highway 126 show unmodeled uplift of 10 to 20 mm in the vicinity of LOVE. We have considered the possibility that the misfits to data here may be due to seismic deformation associated with aftershocks, but we find it is not possible to account for the anomalies with the small displacement contributions of the aftershocks. An $M = 5.1$ aftershock that occurred on 19 January 1994 and located at a depth of 11 km was located close to these geodetic anomalies. This event had a pure reverse mechanism and is associated with seismicity on a north-dipping plane. The $M = 4.9$ aftershock on 26 June 1995 also occurred in this vicinity. If one postulates that some aseismic slip may have occurred on this north-dipping plane, it may be possible to improve fits to the geodetic data in the vicinity of stations LOVE and NEWH and along the highway 126 level line.

This apparently anomalous crustal deformation surrounds the intersection of the eastern Ventura Basin with the San Gabriel fault. It occurs in the area where the aftershocks most notably do not fall within the area of our model fault planes (Fig. 2). Furthermore, this area produced four preshocks $1.3 \leqq M \leqq 1.9$ at a depth of about 15 km within the 16 hr before the mainshock, called the Holser cluster (Hauksson *et al.*, 1995). It is not yet clear whether the prox-

imity of these preshocks and some larger aftershocks to the anomalous geodetic measurements is purely coincidental or may have a physical connection.

Fault Geometry and Material Properties

We are convinced from recent work on relocating the aftershocks by Mori *et al.* (1995) and Hauksson *et al.* (1995) that the fault geometry is more complicated than either a single uniform-slip dislocation or distributed slip on a single plane. Those studies indicate that the rupture almost surely occurred on a more complicated structure, so the geometry of our model is too simple. For example, the dip is shallower in the eastern portion of the aftershock zone than in the western portion. It is also possible that some shallow sympathetic slip may have occurred on a plane nearly parallel or perpendicular to the plane the mainshock occurred on, as suggested by south- and north-dipping features in the hanging-wall seismicity (Hauksson *et al.*, 1995). In addition, the seismicity indicates a somewhat deeper north-dipping structure near the northwestern up-dip corner of the rupture (closest to the anomalously displaced GPS stations U145, NEWH, and LOVE). The possibility of slip on other faults, particularly in the hanging wall, is investigated in Shen *et al.* (this issue). The geodetic data would be sensitive to even relatively small amounts of sympathetic slip on shallow structures, but future refinements of the modeling will be required to isolate any such affects. Geologists' formulations of the processes by which folds form (e.g., Suppe, 1985) include specific processes of localized deformation within the hanging wall; we do not attempt to take these into account here. Furthermore, we do not account for variable material properties within the earth's crust, and again, this may be a source of misfit. The challenge of adequately fitting our GPS results, perhaps with a more realistic fault geometry and/or more reasonable model of the crustal structure, remains to be met.

Preliminary Comparisons with Other Data

The pattern of uplift determined by extensive releveling (performed by the City of Los Angeles, National Geodetic Survey, and Caltrans) is roughly compatible with the models presented here. However, initial work with the leveling data has indicated that the total moment of our variable slip model is probably too high by about 20%. We also recognize that details of slip on the shallowest subfaults in the variable slip model presented here are not well resolved by the GPS data alone and that the leveling data will allow better imaging of the shallow slip. Furthermore, Murakami *et al.* (in press) have provided the first SAR interferometry results for the Northridge earthquake, and our variable slip model generally matches these independent data (although a lower total moment would also help us to match the SAR results better). We recognize at this stage that our uniform slip model is less consistent with either the leveling data or the SAR interferogram than is our variable slip model.

General Observations and Implications

The Northridge earthquake caused uplift of the Santa Susana Range, which seems intuitively sensible in terms of long-term displacement patterns. That is, the mountains, unsurprisingly, were pushed up by at least 400 mm (from our measurements at Oat Mountain), and perhaps as much as 520 mm (based on the maxima from our variable slip model). The largest amounts of uplift caused by the Northridge event fall along the crest of the Santa Susana range. More perplexing is our observation that the northern edge of the San Fernando Valley was also pushed up. It is difficult to reconcile this observation with the geomorphology of the area. The valley was pushed up less than the mountains, but nevertheless uplift of more than 200 mm occurred in Northridge, well south of the mountain front. Though we have only a few GPS stations within the San Fernando Valley that indicate uplift, preliminary releveling results show as much as 200 to 400 mm of uplift throughout the northern portion of the valley. Observed uplift of the northern San Fernando Valley qualitatively appears to conflict with the topography that has presumably been built, in large part, by prehistoric earthquakes.

The southward dip of the rupture plane in this event indicates that the fault is a backthrust, dipping contrary to the Sierra Madre fault system's orientation. The Oak Ridge fault system to the west also dips southward, implying that the Northridge earthquake occurred on an eastern extension of that fault system (e.g, Yeats, 1994). The Northridge fault plane, in turn, seems (from the aftershock seismicity) to be truncated at the upper edge by the fault that ruptured in the 1971 San Fernando (also known as Sylmar) earthquake (USGS and SCEC, 1994; Mori *et al.*, 1995). We appear to have imaged the up-dip truncation of slip at a depth of 4 to 6 km with our variable slip model (Figs. 3 and 5). This is slightly shallower than the intersection depth indicated by the seismicity. In places, the aftershocks extend spatially beyond the edges of the slip distribution model that we find best explains the geodetic data, especially near the northwest up-dip corner of the model fault (Figs. 2 and 3).

Slip in the Northridge earthquake was concentrated between depths of 5 and 20 km. Geologists have found no compelling evidence for a primary surface rupture (USGS and SCEC, 1994). Modeling indicates that in parts of the Santa Susana Range where we had no geodetic stations, uplift of as much as 520 mm may have occurred. In contrast, the 1971 earthquake, which was similar in magnitude, had large amounts of shallow slip and produced clear surface faulting (e.g., Heaton, 1982). As a result, the 1971 earthquake also produced much larger maximum displacements and commensurately larger strains and tilts at the ground surface (e.g., Savage *et al.*, 1975; Cline *et al.*, 1984). In that case, up to 2.5 m of vertical motion occurred over distances of 5 to 10 km, whereas the wavelength of vertical displacement associated with the Northridge event was several times longer as a result of the deeper concentration of large slip.

Conclusions

The displacement field of the earthquake was sampled by determining displacement vectors at 66 sites with respect to a time-dependent, well-established reference frame for global GPS tracking stations outside of southern California. The mean 1-sigma errors in these data are 8 mm (east–west), 6 mm (north–south), and 23 mm (vertical). From these precise measurements, we have quantified the displacement field associated with the Northridge earthquake (and its early aftershocks). The resulting data set, presented in Table 1, is of high quality and potentially high utility in understanding the earthquake. The data quality may, we hope, take others beyond the simple modeling efforts we have advanced in this article.

As a result of performing extensive analyses of the GPS data set, we feel that we understand the errors in the GPS data well enough to expect our models to fit these data appropriately within the stated errors, except for undetected problems at the less frequently measured stations. The exact reasons why our relatively simple models do not satisfactorily explain these GPS data remain unresolved, though we discuss the relevant issues and speculate that, perhaps most importantly, the source was too complex to be represented adequately with any single-plane model. The fact that we are not able to match the observations in a fairly well localized region to the north of the near-surface part of the fault plane suggests that the primary cause of the mismatch is using too simple a model, rather than monument instability.

From our GPS measurements, we produced a single-dislocation model independent of seismological and other information. Furthermore, the data were sufficient to allow an inversion in order to estimate the distribution of slip on the main fault plane. The observed displacement field was evidently produced mainly by slip on a SSW-dipping reverse fault in the mid-crust, under the northern edge of the San Fernando Valley. The Santa Susana Range was uplifted by the earthquake by as much as 400 mm (measured) to 520 mm (modeled), and the northern part of the San Fernando Valley was uplifted by more than 200 mm. The pattern of uplift caused by the Northridge earthquake appears discordant with the topography. Both of our modeling approaches indicate that in order to explain most of the variance in the GPS data, the largest amount of slip must have occurred up-dip and northwest of the event's hypocenter. We find that less than 1 m of slip occurred above a depth of about 5 km. We appear to have confirmed the suggestion by Mori *et al.* (1995) that the subsurface intersection with the 1971 earthquake fault plane formed the up-dip terminus of slip in the Northridge earthquake.

Our modeling indicates a simpler slip distribution than has been inferred on the basis of seismological data alone (Wald and Heaton, 1994b; Dreger, 1994). Clearly, the geodetic data and seismological data do not invoke identical images of the slip distribution. We present our variable slip model here partly to emphasize this point. Seismological data indicate slip concentrations near the down-dip edge of the rupture plane, whereas the geodetic data do not (see also; Wald *et al.*, this issue). This may be because there are too few GPS stations in the southern San Fernando Valley to resolve such features, or because contributions of these slip patches to the surface displacement field are too small to resolve with the available GPS data.

Geodetic data are well suited to mapping the final slip distribution of an earthquake and can therefore enhance imaging of rupture propagation beyond the capabilities of imaging based on seismological data alone, as was the case for the Landers earthquake (Hudnut *et al.*, 1994; Wald and Heaton, 1994a). By combining seismological and geodetic data, Wald *et al.* (this issue) attempt to resolve the differences noted above by using the combined seismological and geodetic data sets. It is also possible that the discrepancies seen result from aseismic slip; the geodetic measurements would include such phenomena, whereas the seismological data might not. Seismological and geodetic data are complementary, and combining the seismological data with geodetic data can provide the best available methods for imaging details of the earthquake source.

Acknowledgments

The GPS data used in this study were, in large part, collected through the cooperative efforts of several agencies and institutions. The National Geodetic Survey, Caltrans District 7 and Headquarters, Los Angeles County, and City of Los Angeles were the main surveying agencies that provided us with crucial assistance in GPS surveys conducted both prior to and following the Northridge earthquake. Without the work of these surveying agencies, only a portion of the results obtained in this study would have been possible. Of particular importance were the help of D. D'Onofrio, L. Fenske, R. Packard, R. Reader, and J. Satalich. The leveling results we discuss resulted from work by these agencies, in part supported by a FEMA mission assignment to the USGS under the direction of R. Stein. Also, the various field, logistical, and other efforts of many of our colleagues after the earthquake were greatly appreciated. We thank the following in particular: D. Agnew, J. Behr, E. Calais, K. Clark, M. Cline, G. Franklin, X. Ge, W. K. Gross, G. Hamilton, K. Hurst, D. Jackson, H. Johnson, S. Larsen, G. Lyzenga, D. Potter, M. Smith, J. Sutton, K. Stark, C. Stiffler, F. Webb, J. Zhang, and J. Zumberge. Much of the software used in producing, modeling, and displaying our results is freely available, and we particularly thank the developers of DISL, FONDA, GINV, GAMIT, GIPSY, GLOBK, and GMT who happen not to be co-authors of the present article: G. Blewitt, D. Dong, K. Feigl, K. Hurst, D. Jefferson, S. Larsen, W. Smith, F. Webb, P. Wessel, and J. Zumberge among many others. Though our published results were obtained using the GAMIT/GLOBK software, earlier analyses using FONDA and GIPSY/OASIS-II contributed significantly to the results. M. Murakami kindly provided a preprint of his article on the SAR interferometry results. We thank reviewers R. Stein, J. Mori, T. Heaton, and an anonymous reviewer for their suggestions. The National Earthquake Hazard Reduction Program (NEHRP) supported much of this work, both through the direct support of the USGS, NSF, and FEMA and indirectly through SCEC contracts with MIT, UCLA, and UCSD; portions of the research described in this work were carried out at the Jet Propulsion Laboratory, California Institute of Technology, under contract with NASA; research at UCSD is funded by Grants NASA NAG 5-1917, USGS 1434-92-G2196, NSF EAR 92 08447, and NSF EAR-9416338, as well as through SCEC. SCEC Contribution Number 153.

Table A2
GPS Data Sets (Experiments) Used in This Study

Survey Name	Identity	Time	Type	Length	Lead Agencies
Pre-earthquake:					
HPGN-Densification	HPGN-D2	Oct. 1992	TR-C[1]/P[2]	2–6 hr.	Caltrans/NGS
Inter-County	IC'93	July 1993	TR/AS[3]	6 hr.	USGS/SCEC
Partial HPGN-D net	HPGN-D3	Oct. 1993	TR-C[1]/P[2]	2–6 hr.	Caltrans
Ventura Basin	VB'93	Nov. 1993	OS-TR[4]	24+ hr.	JPL/MIT
Post-earthquake:					
Earthquake response	EQ'94	Jan. 1994	TR/AS[3]	6–24+ hr.	USGS/SCEC
HPGN and HPGN-D	COOP'94	Feb. 1994	TR-C/P[6]	2–6 hr.	Caltrans/NGS
Continuous:	PGGA	all above	TR-P[2], AS[5],	OS-TR[4]	UCSD/JPL

*TR-C refers to Trimble 4000 SST model receivers: dual-frequency L2-codeless. Geodetic control purposes to NGS first-order "group B" specifications.

†TR-P refers to Trimble 4000 SSE model receivers: dual-frequency P-code. Geodetic control purposes to NGS first-order "group C" specifications.

‡The Inter-County 1993 survey used a mix of TR-C/P and Ashtech (AS) C/P receivers.

§OS-TR refers to Osborne TurboRogue model receivers: dual-frequency P-code.

The earthquake response surveys within the first few weeks used a mix of TR-C/P, OS-TR, and AS-C/P receivers. Stations of the HPGN, HPGN-D, IC, and VB nets were occupied. This was a cooperative effort of scientists represented in this article, many of whom are listed in the acknowledgments.

¶The HPGN and HPGN-D network stations within a radius of about 75 km of the mainshock were surveyed in mid-February 1994, cooperatively with local government agencies and SCEC.

References:

October/November 1992—Caltrans HPGN-D. Supervised by Jay Satalich, Caltrans District 7. Processed by UCLA and USGS.

July, 1993—USGS/SCEC Inter-County Survey. Organized by Ken Hudnut, USGS. Processed by UCLA, MIT, USGS.

October 1993—Caltrans HPGN-D partial survey. Supervised by Jay Satalich, Caltrans District 7. Processed by UCLA and USGS.

November 1993—JPL/MIT Ventura Basin Survey (Donnellan *et al.*, 1993a, 1993b). Organized by Andrea Donnellan, JPL. Processed by MIT and JPL.

January/February 1994—USGS/UCLA/JPL/MIT/UCSD postearthquake response surveys (Hudnut *et al.*, 1994). Organized by Ken Hudnut, USGS (IC and HPGN/HPGN-D stations) and Andrea Donnellan, JPL (VB stations). Processed by JPL (VB stations), UCLA (all stations), USGS (all), and MIT (all).

February 1994—Caltrans/NGS cooperative post-earthquake survey. Organized by Don D'Onofrio, NGS and Jay Satalich, Caltrans District 7. Processed by UCLA and MIT.

All of the global and regional GAMIT tracking solutions were produced by UCSD (Fang *et al.*, 1992) and all of those for GIPSY were produced by JPL (Zumberge *et al.*, 1992).

Software used in these data analyses included FONDA (Dong, 1993), GAMIT (King and Bock, 1994), GIPSY/OASIS-II (Blewitt *et al.*, 1993b, Webb and Zumberge, 1993), and GLOBK (Herring, 1993).

Acronym Key:

California Division of Transportation (Caltrans), National Geodetic Survey (NGS), Jet Propulsion Lab (JPL), Massachusetts Institute of Technology (MIT), University of California, Los Angeles (UCLA), Scripps Institute at University of California, San Diego (Scripps/UCSD), and Southern California Earthquake Center (SCEC)—in some places representing contributions of all collaborating universities (MIT, UCLA, UCSD) as well as JPL.

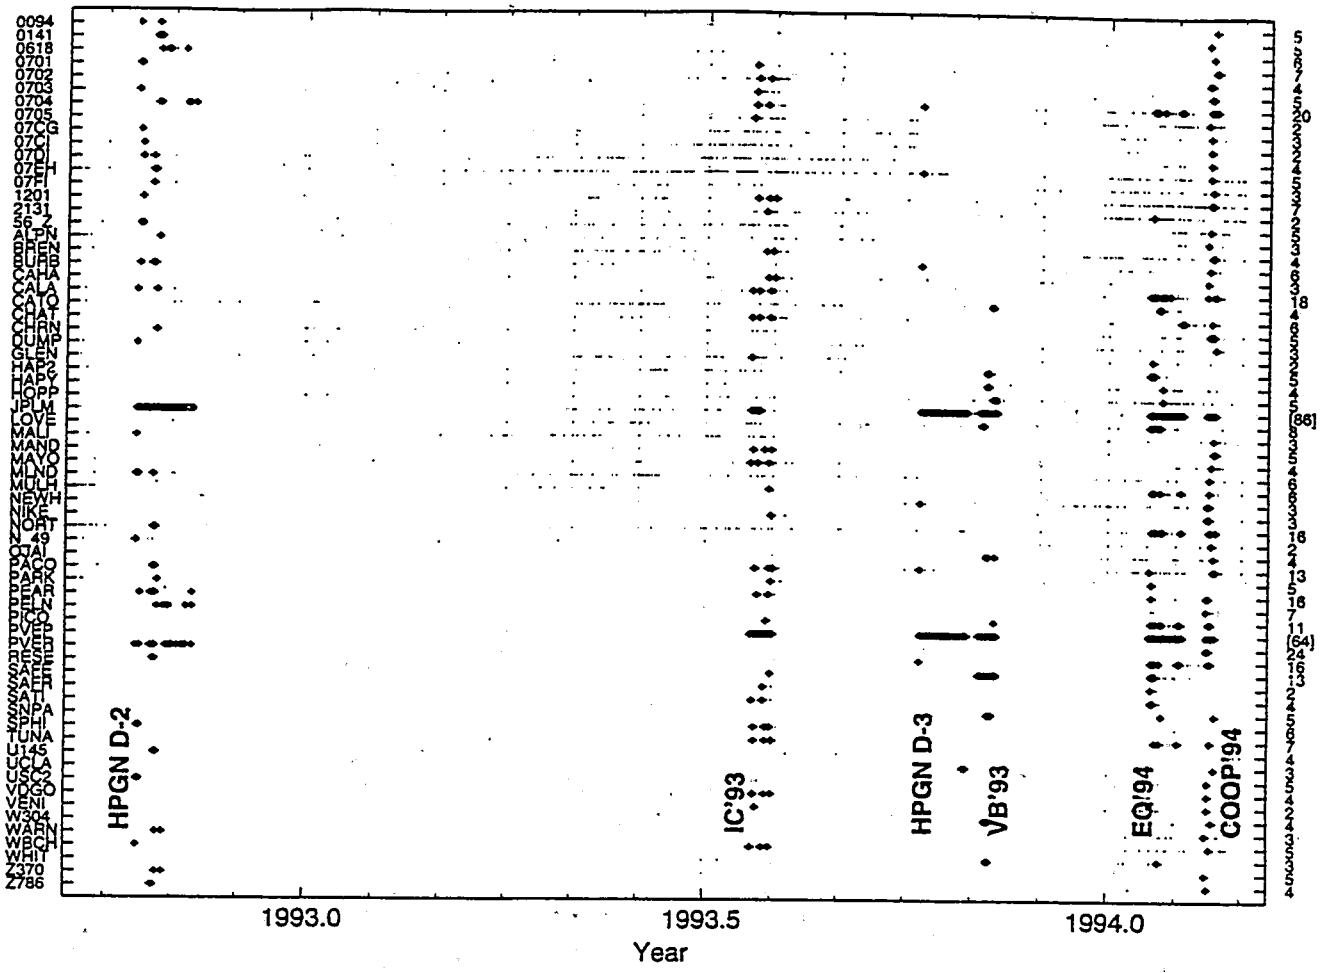

Figure A1. GPS station history of occupations. Station names are given on the left, and the total number of occupations for each station is given on the right. Each occupation is shown as a diamond symbol (except that in the Caltrans/NGS surveys: multiple sessions on the same day are represented by one symbol). Stations with a total of only two or three occupations are most susceptible to coarse errors.

Re:Sunshine Canyon Landfill Project
City of Los Angeles
Department of city Planning- Hearing Examiner
221 S. Figueroa St. 3rd. Floor
Los Angeles, CA. 90012

November 19,1997

Dear Sir/Madam

I do not feel it is prudent to expand the Sunshine Canyon land fill for the following reasons:

- ◇ Proximity to a critical water supply. Both airborne and underground contaminates are dangers. **522**
- ◇ The air quality in the area needs improvement. The landfill will contribute a significant adverse affect on air quality because of the waste itself and the increased traffic. **523**
- ◇ I do not want mature oaks removed and wildlife habitat disturbed. Disturbance of the environmental balance in this area has already been significant. The deer, bobcat, coyotes, and mountain lions in this area will certainly be affected and subsequently the neighboring communities will be affected by these animals **524**

I feel these reasons are very important. I feel that there could be a narrow-minded focus on scientific and economic evidence that can be skewed in either direction depending what side of the issue you are on. I think those entrusted with the decision should consider **common sense.** **525**
Is it probable that the dump won't affect our water,air, and animal habitat? **526**

BFI has submitted a business proposal. It is just one way to solve a waste disposal problem. **527**
BFI's proposal would create both economic hardship and health risk to the community. There are viable alternatives. As an example: I was able to reduce my own non recyclable waste by a whopping two-thirds after receiving my "Blue Bin". Please work harder at finding a solution to our waste disposal problem. Find a way other than expanding this or any other dump. **528**

Sincerely,
Elizabeth Folb

ENVIRONMENTAL
UNIT

Los Angeles City Planning Department
Environmental review Section
221 N. Figueroa Street Room 1500
Los Angeles , CA 90012

To The Los Angeles City Planning Department;

I have reviewed the SEIR for Sunshine Canyon landfill expansion back onto the CLOSED CITY landfill and I have many comments and questions that need to be answered and addressed.

I would like to start by saying that I can not believe that this is even coming back to the City for expansion. I state this because we have **already had 30 plus years** of DUMP on the City side of Sunshine Canyon and the COUNTY side is currently operating and there will be no foreseeable end to the COUNTY operation. 529

The CLOSED CITY DUMP is NOT LINED now and has NO LEACHATE COLLECTION SYSTEM now BFI is proposing to put a liner over unstable trash and add more trash this is a ACCIDENT WAITING TO HAPPEN. 530

In 1988 as part of developing and promulgating Subtitle D regulations governing landfilling of municipal solid waste, the US EPA stated , " First , even the best liner and leachate collection system will ultimately fail due to the natural deterioration , and recent improvements in MSWLF (municipal solid waste landfill) containment technologies suggest that releases may be delayed for many decades at some landfills. " and "Once the unit is closed , the bottom layer of the landfill will deteriorate over time, and consequently , will not prevent leachate transport out of the unit." 531

In reviewing the water section 4.3 of this SEIR:
I wondered if the monitoring data and comments from 1989 are relevant 8 years later? Unfortunately , changes occur and therefore results from any tests on drainage , sedimentation , leachate collection, erosion control and precipitation should be recalculated. 532

How will and how has the existing water uses, residential , commercial and industrial water be affected by this project ? 533

Is the ground water in the San Fernando / San Gabriel Valley area being distributed to households and businesses for consumption now ? 534

When the storm water runoff originating in Sunshine Canyon flows south does it combine with Los Angeles river and go untreated to the ocean ? 535

What year was the rainfall data collected ? 536

What is the annual high rainfall data for the eastern Santa Clara River Valley ? 537
What is the annual low for Mount Islip ? 538
Where is Ducommum street rain gauge ? 539
Was the anticipated El Nino condition considered in this SEIR ? 540
What does Zone C on the flood insurance map mean? 541
What does Zone A mean ? 542

Because the drainage for the landfill converges at the mouth of the landfill , what are the safety mechanisms in place besides the trench now to catch the polluted water from exiting the site? 543

Where is the wash that the water collected in the county travels through located? Is this water tested and then treated ? How is this water treated? What will happen to this wash if the proposed expansion is approved ? 544
What does off site surface water mean ? 545

Has water from the culvert maintained by the City BOE underneath San Fernando Road ever been tested ?
If it has been tested , what for ? What are the results ?
If not then , why not ? 546

If the surface water (water that travels over trash) eventually reaches Sepulveda Dam , does this mean that the water is available for residential, commercial and industrial use ? 547

Are these areas that the water travels through to reach Sepulveda Dam, covered areas to prevent people and animals from coming into contact with it ? 548

What is included with the Industrial storm water permit ? 549
What was revised on the April 17 , 1997 permit ? 550

Which of the NPDES permit program is more stringent, the US EPA or the States ? 551
What are the differences between the programs ? 552
Why did BFI choose the State program ? 553

What are the requirements that need to be met by the SWRCB General Construction Activities Storm water Permit ? 554

On page 4-104 states that the General Industrial Storm Water permit revisions to the NPDES monitoring and reporting program may include ....
what does the General Industrial Storm Water permit include for Sunshine Canyon ? 555

Does the SWPPP have to be specific and how specific for how they will identify sources of pollution , practices they will use to reduce pollutants , assessment of potential pollution sources, etc.? 556

Did BFI file a notice of Intent to develop and implement the SWPPP ? If so when was it filed ? 557

How safe is it to allow the proponent to self inspect the sites storm water discharge? 558
Are they currently in compliance ? 559

Why was the wet season changed to exclude June through September? Is the data then averaged for 8 months ? 560

Figure 4.3-2 shows the proposed drainage plan and clearly shows that the drainage will go over existing trash even if it is through a channel the channel will still be on top of trash, how could this possibly be correct ? 561
The Sediment basin in the County is to be removed and then there will be NO existing collection area in the County . How can the proposed sediment basins B and C possibly contain all the water ? Doesn't this open the door to a major disaster? 562
Figure 4.3-2 shows that the water will flow from the County to the City basins B and C and then the water will **travel over channels, built on trash** which stability is questionable all to converge on basin A. 563
Is this a common engineered design , to build channels on top of trash , how could this possibly be safe ?
Basin A is so far away from the county area of operation , what will happen if there is a blockage in the channel , won't this cause a lake or flood of trash ? 564
What happens if the channel leaks even a small amount couldn't this cause a sink hole type situation ? 565
What emergency plan will be in place ? 566
Doesn't this leave all the stress for water drainage in the city ? 567
If basin A is designed to capture only 41-acre feet of runoff , how can this one basin accommodate all this water ? 568
How specifically will these channels for drainage, inceptor ditches, pipelines and sediment basins be designed to minimize ponding , infiltration , inundation , erosion , slope failure , washout and overtopping. 569

What are the standards of a certified laboratory ? 570
How are these laboratories chosen? By whom are they chosen ? 571
How often are the labs checked for accuracy ? 572

Why is the debris production curve based on the assumption of a "burned " watershed ? 573

In debris production area 6 (DPA-6) an assigned area specifically for Sunshine Canyon ? or are there other ares that have DPA-6 assignment ? 574

What County or City agency makes this assignment ? 575
Why are the Sediment basins being constructed in phases ? 576

After all the dispute about the County being a separate site now they will combine operations and is a clear case that they always sought incremental approval for this project against CEQA. 577

Who will be the lead agencies now ? 578
How will the tipping fees be split between the County and City ? 579

What surface improvements will be made in the existing landfill ? 580
Where will the storm water be dissipated ? 581
What is the proposed testing and monitoring program for the diverted storm water? 582
How does the energy dissipator slow surface water exit velocity ? 583
What is the pre-development maximum value of peak discharge ? 584

The surface water exits the dump site at San Fernando Road , then follows a cracked channel to the Jensen Filtration Plant , where it goes directly to ground. This canyon has received as much as 52 inches of rain a year and has a maximum 100 year , 24 hour projection of 9.80 inches. The base of the canyon is in a 100 year flood plain. Slides , washouts and flooding has occurred at this site before 585

What if the surface water is not able to be treated before entering Bull Creek Channel and Sepulveda Dam ?
How much potential does exist for non-storm water discharge into the storm water conveyance system ? 586
What various measures will be used to separate storm water from wastes being disposed of in the proposed landfill ? 587
What methods will be used to control sedimentation load during construction caused by storm water runoff ? 588
What methods will be used to control debris caused by storm water runoff ? 589
What methods will be used to control erosion caused by storm water runoff ? 590

What are the requirements of the NPDES permit for point source and non-point source discharges ? 591
Where will the water be monitored until the sediment basins are built ? 592
Is the flood control channel the same one that is referred to that is located directly east of the project entrance ? 593
Won't the temporary unlined drainage facilities, consisting of diversion ditches to intercept natural runoff, cause too much erosion if it rains excessively? 594
Isn't vegetation the best way to prevent erosion ?

What is meant by areas of disturbance shall be kept at a minimum during active filling operations? 595
What is minimum disturbance ?
How will this be done ?

What is the best % gradient for final landfill cover to preclude percolation of water ? 596
What is BFI's erosion control plan for Sunshine Canyon ?
When will this be completed ? Who will approve this plan ?

How can any clear thinking person believe that the potential impacts can be mitigated to less than a significant level . 600

This project will put a liner on top of existing trash, 30 plus years of trash that will continue to settle and then they will put over 11,000 tons of trash a day 6 days a week on top. 601
Vinyl Chloride which has a Maximum Contaminant Level of 0.5 ppb has already been detected on the City Side at 5.0 ppb . Vinyl Chloride can rapidly pass through intact without holes FML's (Flexible Membrane Liners). 602

When was the data pertaining to the ground water collected ? 603
Who conducted the exploration borings ? Who decided to where the borings should be taken ? 604
What ground water studies were done ? By whom ? Was this company a BFI subsidiary or a company chosen by BFI or the City / County ? 605

Why is the average horizontal ground water velocity in the fractured bedrock such a wide range (3 to 10 feet per year) ? 606
Don't earthquakes effect the water flow and change the permeability of water ? 607
Were the velocity tests done prior to the 1994 earthquake ? 608

How will the alluvium be removed ? Does this mean trash will be dug up and moved ? 609

How were the estimates of Hydraulic conductivity done ? 610
How were the estimates for ground water discharge velocity made? 611

At this time the ground water flows slowly toward the mouth of Sunshine Canyon and nothing is in place to contain the water which as data shows is high in Chlorides in MW-1. 612

In a letter to Mr. Frank Meneses dated January of 1991 Mr Blevins , Watermaster for the upper Los Angeles River states that the potential for contamination can be mitigated by installing a low permeability cutoff wall to the bedrock in the area of thin alluvium near the outlet area this would collect the water high in Chlorides. And as a fail-safe procedure a monitoring well should be placed in the alluvium a short distance downstream from the cutoff wall. 613
Has this cutoff wall been installed yet ?
Was the extraction trench built instead of the cut off wall ?

I thought that BFI told the County Board of Supervisors ,before they approved the County Project that the cut-off wall was installed through the alluvium and keyed to bedrock across the mouth of the canyon in May 1990. 614
This trench was installed over a weekend without staff from any agency present. 615

Also in the same letter Mr. Blevins that **there was a mistake made in the County Final EIR** document. He states that **THERE IS A HYDROLOGIC CONNECTION BETWEEN SUNSHINE CANYON AND THE GROUND WATERS OF THE SAN FERNANDO BASIN.** 616

In another letter to Mr. Meneses received January 10 ,1991 , the **MWD confirms this HYDROLOGIC CONNECTION. MWD doesn't agree that the ground water movement leaving the landfill would be slow.** 617
Even though the water in the general vicinity has relatively high mineral content . Similar quality ground water reserves are being developed elsewhere in Southern California to deal with the regional water shortage. 618

When were the Hydrogeologic field studies done ?
Who conducted these studies ? 619
How were the Hydrogeologic field studies done ?

I have included copies of two letters one from Mr Blevins and the other from MWD. to verify my comments made above. 620

Where is the Hydrology report by Robert Bean dated July ,1978 available to review? 621
Is this the most recent Hydrology report done on Sunshine Canyon, it is almost 10 years old ? 622

The SEIR states that the alluvium will be removed , how will this be done? 623
Will the trash be removed ?

The SEIR states that seeps and springs that were found in the County , does this mean that there were more wetland areas destroyed than the County final EIR predicted and mitigated for ? 624

How will the seeps and springs even though seasonal be kept from pooling once there is trash on top? 625
How can the public be assured that the stated non-active faults will become active again ? 626
As stated ground water is used for emergency and all surface and ground waters of the State are considered to be suitable or potentially suitable for municipal or domestic water supply. 627
The existing closed City side of the landfill has no liner and will continue to pollute the ground water unlike the County operation area there is no existing leachate collection system and all the leachate can combine directly with the ground water.

This is why it is so important to protect the ground water under the landfill from further degradation.

The Report dated August has indicated that problems do still exist? 628

Will the new monitoring wells be drilled for the proposed expansion ? 629
Will they be sited under the new guidelines of the LAWRWQCB Article 5 of chapter 15? 630
How many Lysimeters are being used now ? Are they in good working order ? 631
Who decided where to place the Lysimeters ?

It is stated that the land in close proximity to the landfill is underlain by Holocene alluvial soils that are liquefiable to shallow ground water. 632
Have any investigations been conducted to assure the public that the same Holocene alluvial soils do not exist in Sunshine Canyon ?
If so when and how and by whom was this done ? 633
The landfill is in an area of active faults. The neighbors of the landfill who lived through the 1971 Sylmar Quake and the 1994 Northridge quake know that this area is seismically active. Homes were severely damaged , or condemned. In 1971 Van Gogh Elementary School , which is just South of the landfill, had to be closed for a long time just to repair the damages. Because of the 1994 quake the school had to be demolished. North of the landfill , adjacent to the County site , freeway bridges collapsed completely in both the 1971 and 1994 quakes experiencing what Cal Trans said to be the highest G forces recorded in the Northridge Quake. 634
To the East , the Van Norman Dam cracked, the community beneath it was evacuated in 1971 , and the Dam was later reconstructed as the Los Angeles Reservoir.
Fortunately, the Dump was very small at the time (before BFI purchased it).
The California Department of Mines and Geology recorded a huge landslide on Dump property, that was the largest slide produced by the quake of 1971.
Researchers from the U.S. Geological Service consider this area of the Santa Susanas to be one of the most active landslide areas in the entire world.
In 1994, the Balboa Inlet Tunnel which brings California Aqueduct water to Los Angeles for treatment, was severely damaged. The records at Cal State Northridge show 3 small quakes , whose epicenters are in Sunshine Canyon.
The Alquist maps show active faulting extending into the site. BFI discounts this , based on an extrapolation form a letter written by Mr. Saul , of Mines and Geology. 635
However , when Mr. Saul was asked about this letter he said that he just did not see the fault where they had trenched, not that it wasn't there. He also said that the Santa Susanas were among the most faulted and folded ranges in California.

The Santa Susan Fault, that runs through the current berm , was declared to be inactive in the County EIR. Now , the County has declared it to be active , based on its seismic studies of Brown's Canyon. State Law prohibits , in Subchapter 15 , the siting of new landfills on Holocene faults. This landfill sits on the upper plate of the thrust fault. 636
Can earthquake faults act as conduits for water ? 637

The water in the Los Angeles Reservoir is 2 miles away and holds Post treated and filtered water . The only disinfectant treatment is done before being released to the public it is not filtered again. Any particulate matter (PM10's) including dust and bird droppings that fall into the water remain in the water.
The Reservoir is so large that it can not be covered to prevent this airborne contamination. 638

To state that there will be no impact is far from a true statement.

One of MWD's concerns was about the Balboa Inlet tunnel , which carries imported water from the State water project to MWD ' s Jensen Filtration plant and to the DWP's Aqueduct Filtration plant which together supply approximately 3 1/2 million people , the inlet tunnel is located immediately east of the landfill.
MWD states that because this tunnel runs directly underneath the drainage path leaving the landfill site, if the landfill leakage saturates the geologic formation surrounding this tunnel, hazardous landfill leachate could seep into the tunnel.

The following excerpt was taken from the findings of the State Water Resources Board (September 17,1992) 639
"The Metropolitan Water District of Southern California owns the Balboa Inlet Tunnel, which conveys untreated drinking water to the Jensen Filtration Plant. The 14 -foot tunnel comes within 500 feet of the eastern boundary of the existing landfill (closed City side) situated at the mouth of Sunshine Canyon. The top of the tunnel , at its shallowest point, lies 25 feet below the surface. Depth to ground water , at the same location is about 10 feet or less. Dependent upon flow rates , the hydraulic pressure head in the tunnel is approximately 3 to 19 feet lower than the ground water level. Under these conditions water may seep into the tunnel."

MWD and DWP are not capable of treating landfill leachate so they requested that BFI construct and operate a monitoring system between the landfill and the tunnel. 640
Is this monitoring system in place now ?

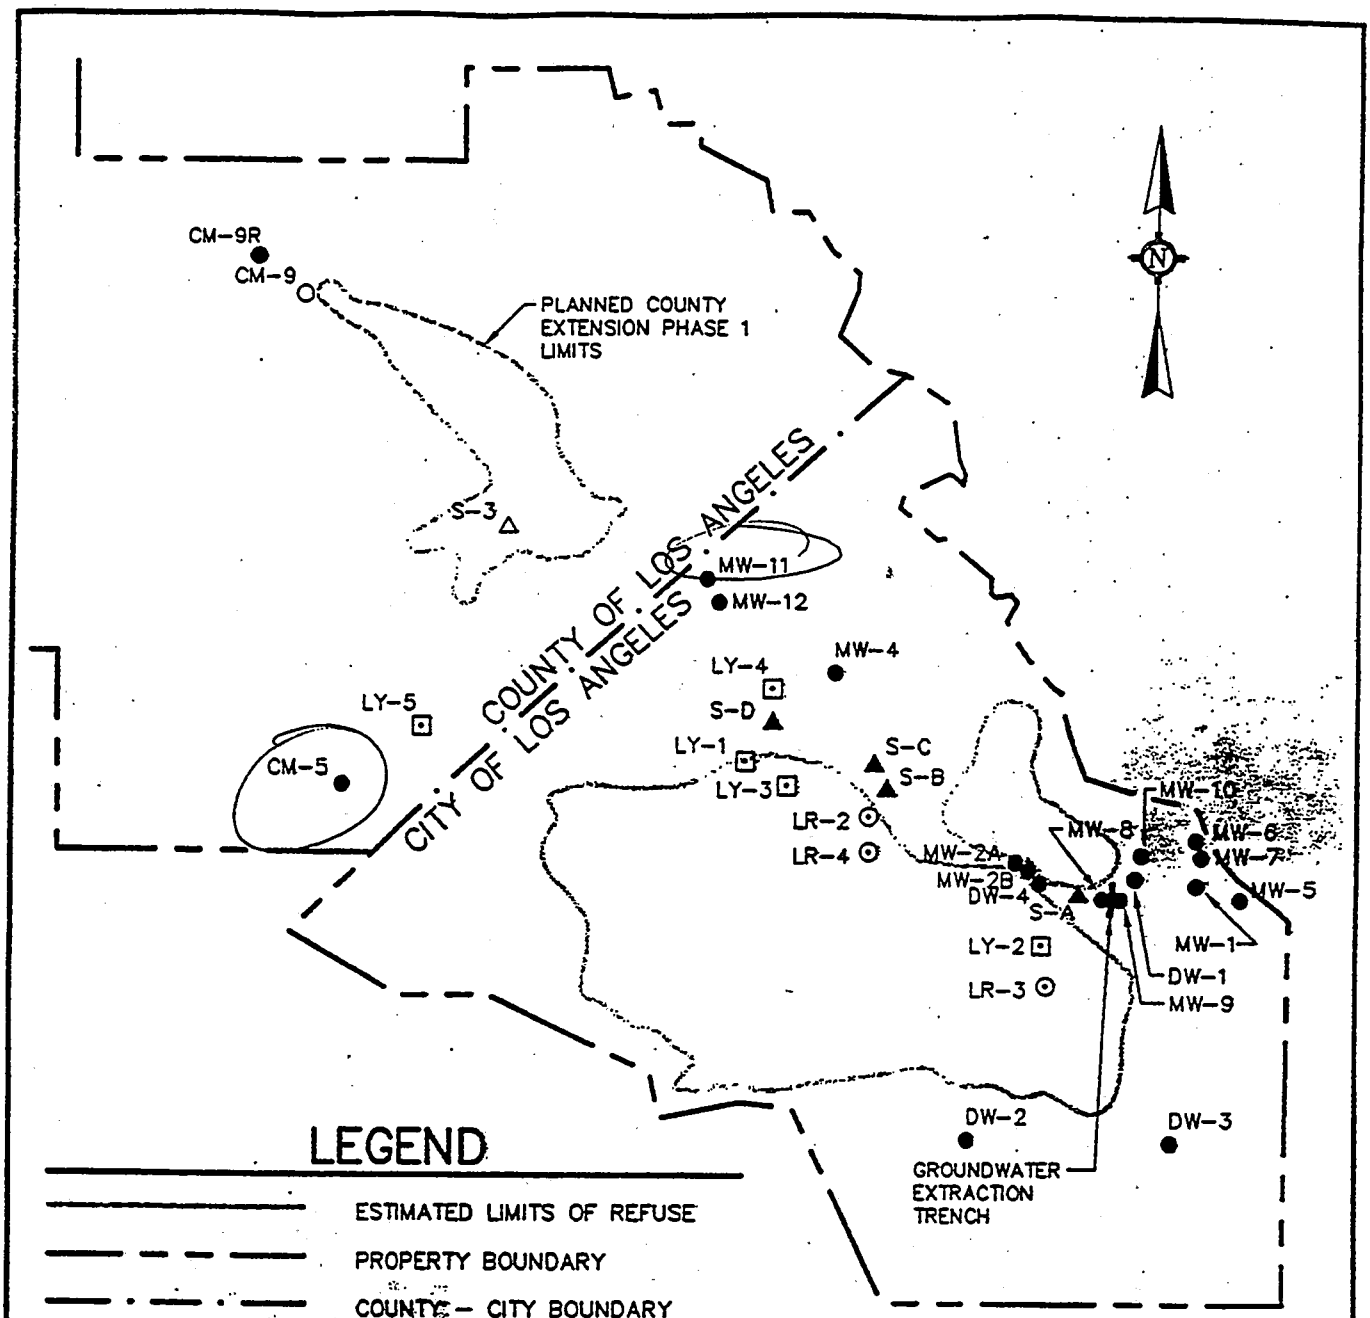
It is stated that the water beneath Sunshine canyon is of poor quality and is not potable, however, you do not state that the water is still treatable if not contaminated by leachate, is it not ? 641
Water is useful for more than drinking. 642
As MWD previously stated in a letter to Mr. Meneses of the County, the water in the general vicinity of the landfill has relatively high mineral content . However , similar quality ground water reserves are being developed elsewhere in Southern California to deal with the regional water shortage situation. Although brackish water desalination technology has become technically and financially attractive in recent years allowing improved basin management strategies for brackish ground water, such technology would not probably treat all landfill contaminants. 643

MWD also mentions that they are concerned about the High Chlorides found in MW-1 and felt that BFI's assertion that these high levels were attributable to nearby oil drilling activities and natural geologic conditions unsupported . 644

MWD goes further to state that because the explanation of high chlorides values is not provided , they recommend that a comprehensive analysis be conducted and submitted to the LARWQCB for its independent assessment of the leakage. 645

Is this the same report that has not yet been approved by the LARWQCB ? 646

How long has this been since the request from MWD to conduct this analysis of the high chlorides ? 647



The MWD thought that the project should not go forward until the high chloride problem was resolved and it has been a long time now and the chloride issue is still not resolved . 648

Even if the high Chlorides are found to be from oil drilling as BFI states , are they still responsible for cleaning this up , after all they lease out the property that the oil wells are drilling upon ? 649

I reviewed the second quarter ground water and waste disposal report for Sunshine Canyon , inactive City landfill.
I wondered why they are allowed to monitor themselves and chose the laboratories to conduct their own testing without any check and balance system ? 650

In their August 1997 ground water monitoring and waste disposal report BFI has reported that there was detection of VOLATILE ORGANIC COMPOUNDS, 1,1-Dichloroethane , Chloroethane , Trichloroethane in Monitoring Well 10 (MW-10). MW-10 is located near MW-1 which is near the mouth of Sunshine Canyon.

In the same report Chloromethane was detected in two Monitoring Wells CM-5 and MW-11 . According to the map included with the August 1997 report these Monitoring Wells are located very near the IMAGINARY COUNTY SIDE / CLOSED CITY SIDE BOUNDARY. CM-5 is on the County Side and MW-11 is on the City side and are at opposite ends from one another.. The ground water in these Monitoring Wells is found at 18-19 feet. 651
I have included a copy of the map that shows the distance between these Monitoring Wells.
BFI claims that this Chloromethane is believed not to originate at the landfill because they are up gradient form the CITY side . This explanation seems to have no foundation.
They say that they will continue to monitor this in the future.

Los Angeles, California 90012

Dear Mr. Meneses:

Final Environmental Impact Report
Project No. SP86312, Case 2556
Sunshine Canyon Landfill Expansion

This letter is intended to clarify my opinion on the hydrologic connection between the Sunshine Canyon area and the groundwaters of the San Fernando Basin. Contrary to the statement in Topical Response 6 in the final EIR, it is my opinion that there is a hydrologic connection between the Sunshine Canyon area and the groundwaters of the San Fernando Basin. This connection occurs only through the thin alluvium beneath the outlet for surface drainage. In this regard, there is complete agreement with the statement in the second paragraph in the letter from Metropolitan Water District (MWD) to you dated January 8, 1991.

The potential for contamination can be fully mitigated by a low permeability cutoff wall to bedrock in the area of thin alluvium near the outlet area. The small volume of high chloride water collected behind this cutoff wall could be removed from a large diameter well and used for moisture control on the landfill. As a fail-safe procedure, a monitoring well should be placed in the alluvium a short distance downstream from the cutoff wall.

As ULARA Watermaster, I have met with Mr. Dean Wise, District Manager for BFI, Mr. Andrew Sienkiewich of MWD and the North Valley Coalition of the Granada Hills area (arranged by Ms. Sue Vila) on separate occasions to better understand the

9B

issues related to the Sunshine Canyon Landfill Expansion. I plan to attend the hearing of the County Board of Supervisors on January 17, 1991. If I can be of further assistance, please contact me at (213) 481-6177.

Sincerely,

ORIGINAL SIGNED

Dear Mr. Meneses:

Final Environmental Impact Report
Project Number SP 86312, Case 2556
Sunshine Canyon Landfill Expansion

We have reviewed the Final Environmental Impact Report (EIR) for the Sunshine Canyon Landfill Expansion. The comments herein represent Metropolitan's comments as a potentially affected public agency.

Request by the County Board of Supervisors

At its November 29, 1990 meeting, the Los Angeles County Board of Supervisors indicated that it would like to receive an official response from the Metropolitan Water District of Southern California regarding the Sunshine Canyon Landfill Expansion project's potential affect upon local water quality. Metropolitan believes the project would threaten local water quality if not properly designed and maintained.

The following factors, which are descriptive of modern municipal waste landfills, form the basis for Metropolitan's concerns:

* Waste deposited in landfills will contain household hazardous substances;

* Landfill wastes will not degrade into a benign state and will always have the potential for contamination until removed; and

* All lining systems are permeable and subject to leakage.

Metropolitan does not oppose the Sunshine Canyon Landfill Expansion. Metropolitan is concerned, however, that local water resources and conveyance systems be protected from contamination. The primary deterrents to contamination will be

9D

Pg 2064

engineered protection systems for leachate control and responsible project management. It is also important that the project be regulated to ensure that these deterrents are effectively implemented.

Imported Water Tunnel

Metropolitan's Balboa Inlet Tunnel is located immediately east of the landfill, running directly underneath the drainage path leaving the site. This tunnel is a major drinking water conveyance facility serving approximately three and one-half million people, primarily in Los Angeles and Ventura Counties. If undetected landfill leakage saturates the geologic formation surrounding this tunnel, hazardous landfill leachate could seep into the tunnel.

Additionally, the Balboa Inlet Tunnel supplies State Water Project water to Metropolitan's Joseph Jensen Filtration Plant and to the Department of Water and Power's Los Angeles Aqueduct Filtration Plant. Neither of these filtration plants has the capability to treat landfill leachate. It is, therefore, essential that landfill leachate does not enter this tunnel.

Metropolitan requests that the project sponsor construct and operate a monitoring system located between the landfill and the tunnel. This system should also be maintained permanently, or until all landfill wastes have been removed from the site.

Metropolitan's Previous Comments on The Draft EIR

Based on our review of the document entitled "Responses To Comments, Volume A" and discussion with the applicant's consultants regarding our October 4, 1989 letter (enclosed), we have the following additional comments:

Hydrologic Connection to the San Fernando Basin

Sunshine Canyon is hydrologically connected to the San Fernando Basin. Upon consultation, Metropolitan and the Watermaster for the Upper Los Angeles River Area both disagree with the response statements (pages 17, 26, 27 and 91, Volume A) asserting the connection does not exist. However, Metropolitan does not disagree with the EIR finding that groundwater movement leaving the landfill area would be relatively slow.

Metropolitan concurs with the EIR findings that groundwater in the general vicinity of the landfill has relatively high mineral content. However, similar quality groundwater reserves are being developed elsewhere in Southern

9E

California to deal with the regional water shortage situation. Although brackish water desalination technology has become technically and financially attractive in recent years allowing improved basin management strategies for brackish groundwater, such technology would probably not treat all landfill contaminants.

Existing Landfill Leakage

Metropolitan previously commented that contaminants may be leaking from the existing landfill and that this problem should be corrected before the landfill is expanded. We noted high chloride values observed at the down-gradient monitoring Well No. MW-1. Topical Response No. 9 (page 25) and Response No. 25 (page 91) of Volume A assert that the high chlorides are attributable to other sources, such as nearby oil drilling activities and natural geologic conditions. Metropolitan finds that the supporting arguments for Response No. 9 lack a straightforward technical analysis of the monitoring well data.

Because an understandable explanation of the high chloride values at Well No. 1, MW-1 is not provided, Metropolitan recommends that a comprehensive analysis of the monitoring well data be conducted and submitted to the Los Angeles Regional Water Quality Control Board (RWQCB) for its independent assessment of the leakage. If leakage is detected, the problem should be corrected before the subject expansion is approved.

Metropolitan has contacted the project engineers, Purcell, Rhodes and Associates. They have advised Metropolitan of plans to construct a gravel drain and pumping system to intercept potential leakage as part of the closure plan for the existing landfill. While this concept seems reasonable, we recommend that any doubts about leakage be resolved by the RWQCB through review of a report as suggested above.

Water Agency Coordination

Metropolitan's comments provided above have been coordinated with the the Los Angeles Department of Water Power and the Watermaster for the Upper Los Angeles River Area.

9F

Points of Contact

We appreciate the opportunity to provide input to your planning process. Please direct questions regarding groundwater quality to Mr. Andrew Sienkiewich at (213) 250-6230. If we can be of further assistance, please contact Dr. Roberta L. Soltz, Manager of Environmental Affairs for Metropolitan, at (213) 250-6437.

Very truly yours,

Carl Boronkay
General Manager

Attention Mr. Robert P. Ghirelli

9G

Why is there no investigation to discover the reason that the Chloromethane was detected? 652

Could this be an indication that contamination is spreading? 653

What type of testing or investigation would be needed to discover the reason for this Chloromethane existence? 654

Chloroform was also detected in station S-D. They state that Chloroform is a trihalomethane and that it is commonly detected in municipal water supplies as a disinfection by-product. They also state that this did not originate at Sunshine Canyon, because S-D is up gradient from the landfill . 655
THEN WHERE DID IT COME FROM ?

WHAT IS NOT STATED IS THAT TRIHALOMETHANES ARE PRODUCED BY THE INTERACTION OF CHLORINE WITH ORGANIC MATERIAL. 656
COULD THIS BE SOMETHING THAT COULD OCCUR WHEN WATER COMES INTO CONTACT WITH ORGANIC MATERIALS THAT MAY BE FOUND AT A LANDFILL ?
AREN'T THM'S SUSPECTED CARCINOGENS? 657

In the same report, ground water levels in most of the Monitoring Wells had decreased but, three of them showed an increase. The amount they decreased is given but the levels of increase are not given. 658
How much of a ground water level increase was present for MW-8 , DW-3 and CM-9R?

What is meant by a general decrease ? 659

What is meant by the ground water was found to occur generally under confined conditions ? 660

When it is stated that the ground water velocity was estimated, Is this the same method used by MWD and DWP ? 661
How can the velocity be measured ?

What is the typical range of hydraulic conductivity for Sunshine Canyon ? 662
How was this range chosen ?

What is the work plan describing the investigation of the presence of VOC's in MW-10? 663

What company conducted the investigation ? 664

It has been a year since the investigation started . 665

What if any results have been found ?

In this report ,what is considered the maximum contaminant level for VOC's found in Leachate ? 666
In Leachate Monitoring Well 4 (LR-4) shows that 50 ppb of ethylbenzene and 5 ppb vinyl chloride was discovered.

According to the appendix (C19) the maximum contaminant level for vinyl chloride (Chloroethene) is 0.5 and the tests results for LR-4 was 5 ppb, Is anything being done to find out why this level exists ? 667

What explains these levels at this particular Well because the other Leachate Monitoring Wells did not show such levels ? 668

There are a few SYNTHETIC VOLATILE ORGANIC COMPOUNDS THAT WERE HIGHER THAN THE MAXIMUM CONTAMINANT LEVEL (MCL) 669
THE LAB TESTS DONE ON A SAMPLE FROM **LR-2** ON 6/2/97 SHOWS THAT **BENZENE WAS 3 ppb HIGHER** THAN THE MCL OF 1 ppb.

1,4-DICHLOROBENZENE WAS 3.4 ppb HIGHER THAN THE MCL OF 5 ppb. 670
THE LAB TESTS DONE ON A SAMPLE FROM **LR-4** ON 6/2/97 SHOWS THAT 671
BENZENE WAS 2.7 ppb HIGHER THAN THE MCL OF 1 ppb.

1,4-DICHLOROBENZENE WAS 10 ppb HIGHER THAN THE MCL OF 5 ppb. 672
THE LAB TESTS DONE ON A SAMPLE FROM **LR-3** ON 6/2/97 SHOWS THAT 673
1,4-DICHLOROBENZENE WAS 5 ppb HIGHER THAN THE MCL OF 5 ppb.

THE MCL FOR CHLORIDES IS 500ppb , **LR-2 AND LR-3 HAD EXCEEDED THE MCL , LR-2 WAS 411 ppb HIGHER AND LR-3 WAS 900 ppb HIGHER.** 674

LR-2 AND LR-3 ALSO EXCEEDED THE MCL FOR TURBIDITY WHICH IS 5 ppb FOR GROUND WATER. LR-2 WAS 3.4 ppb OVER THE MCL AND LR-3 WAS 37.1 ppb OVER THE MCL. 675 676

AND ALSO HIGHER FOR TOTAL DISSOLVED SOLIDS WHICH HAS A MCL OF 1000 ppb. LR-2 WAS 2560 ppb OVER THE MCL AND LR-3 WAS 1980 ppb OVER THE MCL. 677

THE **SURFACE WATER TESTING SHOWS THAT S-A ,S-B, S-C ALL EXCEEDED THE MCL FOR TOTAL DISSOLVED SOLIDS OF 1000 ppb BY AT LEAST 1500 ppb.** 678

S-A WAS 1670 ppb OVER THE MCL , S-B WAS 2140 ppb OVER THE MCL and S-C WAS 2120 OVER THE MCL. 679

Is the HELP model widely used in the waste industry? If so , where has it been used ? 680
Why was the HELP model chosen ?

Doesn't this method grossly underestimate the amount of leachate that will be produced over an extended period of time ? 681

Is there any other method that is used to predict leachate production , estimate surface runoff and drainage ? 682

Is HELP based on ideal situations ? Is there an error factor ? 683

How much moisture can be transmitted through the cap annually if the design specifications are achieved in the construction ? What is the anticipated increase in cap permeability with age ? How will the amount of moisture that penetrates the cap change as the permeability of the cap increases with age ? 684

How did the preliminary design of the project site indicate that infiltration would be lessened by reducing the area of percolation in the canyon? 685

How can the area of percolation in the canyon be reduced? 686

What materials were reviewed to make the conclusion about landfill leachate decreasing in pollution load over time? Where can these references be obtained for review ? 687

What observed studies were done that show leachate will decrease substantially in concentration upon landfill closure ?
Where can these studies be obtained ? 688

The HELP model estimates leachate production based on the County production rate of 120 gallons per minute. What will happen after the landfill is full , the County side has only been open for a short time ? 689

What will happen to this 120 gallons per minute of untreated leachate when the leachate collection system is closed in the County operating area ? 690

Is this untreated leachate to travel through the County area and into the City all the way to the proposed leachate collection system on the City side ?
How far will this untreated leachate travel total ? Will it travel in pipes over the old landfill? 691

This seems like it has great potential for disaster. If any earthquake occurs and cracks any pipe carrying leachate, what is your plan to handle the spill? 692

The proposed LCRS drainage network will be able to withstand how large a seismic event ? 693

What size seismic event will the HDPE pipe be able to withstand ? 694

What is meant by the drainage network will have the ability to deform without leakage ? 695

Why is rainfall data from 1969 relevant in 1997 ? Be realistic. Why are we preparing for El Nino conditions ? 696 Do you think that the same rain that falls less than a mile away from the landfill will not fall onto the landfill ? 697 Is there not more recent data on rainfall information than 1969 ? 698

What design and operational characteristics will ensure the integrity of the ground water resources and its quality within Sunshine Canyon ? 699

What environmental protection and control systems will ensure the integrity of the ground water resources and its quality within Sunshine Canyon ? 700

Who will do this continuous monitoring during landfilling operations , closure and post closure that will ensure the integrity of the ground water resources and its quality within Sunshine Canyon ? 701

The ground water is already impacted by the nonoperating City landfill how can anyone state with honesty that there is not expected to be an impact, what does not expected mean ? This is a non-committal statement. 702

When has there ever been any landfill company that was in total compliance , without any warnings or violations ? 703

When it states that the impacts would be less than significant if the operator stays in compliance , Can this really happen ? Be honest now. 704

Does the RCRA Subtitle D, 40 CFR part 258 , Subpart D ss 258.40 (design criteria) take into account that the liner will be placed on 30 plus years of landfill that will continue to sink ? 705

What will happen over time as the gap between the old trash and this proposed liner widens ? 706

Where will the holding tank for leachate be located ?
Will it be permanent or temporary?
Where will the pipes that carry this leachate run, on top of trash , underneath the trash?
Is the LCRS design based on the 120 gallons per minute of leachate ? 707

This idea to add a liner over a landfill that is 30 plus years old and unlined is puzzling and reminds me of the trash bag commercial where too much trash is put into a plastic bag and as it weakens , it bursts open causing a big mess. The only difference is that if it happens at this site the mess would be of extremely serious proportions. 708

I would like to close with one very important question , would you like this project if you lived near it and your children attended school less than a mile from it ? 709

Please answer honestly.

Mrs. Anne Zitlak

1. Is there a hydraulic connection between the landfill and aquifer potentially affected by the landfill and groundwaters beneath adjacent properties that could, at any time in the future, be used for domestic water supply purposes? 710

2. Will the landfill design (cap, liner, leachate collection-removal system, etc.) prevent leachate from being formed in the landfill, and prevent leachate's leaving the landfill through the liner system for as long as the wastes in the landfill represent a threat to groundwater quality? 711

3. How much leachate will be generated annually in the landfill over the period during which the wastes represent a threat to groundwater quality? 712

4. How will desiccation-cracks and differential-settling cracks in the cap of the landfill be detected and remediated? 713

5. What will be the costs, and how and by whom will the costs be paid, for cap maintenance for as long as the wastes represent a threat to groundwater quality? 714

6. What will be the rate of leachate transport (gallons/acre/year) through the landfill liner and out of the leachate collection and removal system through the liner at the time of construction? How will the leakage rates change over the time that the wastes in the landfill represent a threat to groundwater quality? What is the potential impact of such leakage on groundwater quality in the vicinity of the landfill? 715

7. For landfills incorporating composite liners, what will be the potential impact of desiccation-cracking of the soil-clay layer of the composite on the rate of leachate transport? What is the anticipate area of the liner in which intimate contact between the FML and the soil-clay layer will not be achieved? What will be the impact on the rate of leachate transport of not achieving intimate contact between the FML and the soil-clay layer over that area? 716

8. How will the problem of desiccation-cracking of the compacted soil layer of the composite liner be identified, and remedied? How will the desiccation-cracking that occurs affect leachate transport through the liner? 717

Permitting of Landfills (continued)
Questions

9. What is the expected composition of the leachate? What is the potential for each of the components to pollute groundwater in the vicinity of the landfill, rendering it unusable or impaired for use as a domestic water supply? 718

10. What is the potential for TCE and other chlorinated solvents in the proposed landfill to pollute groundwater with known human carcinogens? 719

11. What is the potential impact of any possible seismic activity that could occur in the vicinity of the landfill on the landfill structures? After a seismic event of any magnitude, how will the integrity of structures be examined and damage assessed before widespread groundwater pollution occurs. How will it be possible to make repairs on those structures when they are located beneath buried solid waste that may be hundreds of feet thick? 720 721

12. What is the ability of the groundwater monitoring system proposed to detect leakage from the landfill liner before widespread groundwater contamination occurs? 722

13. Can municipal solid waste leachate-contaminated aquifers be "cleaned up" to the point at which the groundwater and the aquifer can be used again for domestic water supply purposes? If so, how can this be done? 723

14. Did the consulting firm for landfill design and the EIR/EIS firm make a plausible worst-case scenario evaluation for the pollution of groundwaters by the proposed landfill? Have they estimated the total cost of groundwater and aquifer clean-up to the extent that clean-up can be accomplished? Who will pay those costs? 724

15. What are officials in the local political jurisdiction doing toward investigating and remediating current groundwater pollution from existing landfills, and toward preventing future groundwater pollution by landfills? 725

16. How will the moisture content of the waste in the closed landfill affect the rate of fermentation (gas production) and leaching of contaminants from the wastes? 726

Environmental Review Section
221 N. Figuero Street, Room 1500
Los Angeles, CA 90012

Dear Mr. Plafkin:

We, the Members of the Board of Directors of the Knollwood Property Owners Association, who represent 550 homeowners, are concerned about the impact of the proposed expansion of the Sunshine Canyon landfill on the health of the families who live in this area. 727

We ask you to put yourself in our position and understand our concerns about the proposed expansion. For years we have been shocked by the way Browning Ferris Industries (BFI) has blatantly violated major restrictions placed on them by their operating permits. (BFI has opened areas for dumping when they didn't have the permits, has constantly operated without watering down the active areas as required, has built berms higher than allowed, has not covered raw dumping as required, has continued operations on even the windiest days, and has even delayed inspections.) We are sure you are aware of these infractions. 728

Even if they were to comply with all the precautions as they have promised, which is very unlikely considering their record, we, the residents of Granada Hills, would still be faced with having the world's largest dump in our backyard. 729 According to the Environmental Impact Report the expansion will significantly raise the level of air pollutants in the area. There will be a significant increase in nitrogen oxides, reactive organic gases, carbon monoxide, sulfur oxides, and suspended particulate matter which cannot be mitigated. 730

We understand that the City now has an economic interest in Sunshine Canyon because of the long term reduced price agreed upon by BFI if they are to accept half of the city's refuse. Please assure us that your major consideration will not be economic. 731

Those of us residing in Knollwood and Granada Hills do not feel that we should provide the necessary burial ground to meet the solid waste needs of the city of Los Angeles. We support Councilman Hal Bernson in his suggestion (July letter) that, instead of expanding to within the Los Angeles city limits, it be moved further north. 732

BFI says the landfill will have little effect on the adjacent land uses; however, we know, that they cannot get rid of 100% of the methane gas created by so large a landfill. We know that our very lives and those of our children are in danger if we continue to live here after expansion of the dump. 733

If the proposed expansion is approved by your office the landfill will be a mere 1700 feet from the nearest home. Again we ask you to imagine what our environment will be like if you approve the expansion of the Sunshine Canyon landfill. 734

Sincerely yours,

Iris S. Shah

Iris S. Shah, Ph.D.

RE: Sunshine Canyon Landfill Draft Subsequent Environmental Report (EIR)

Dear Mr. Plafkin:

I have reviewed the Environmental Impact Report at the request of my son, William F. Salle who is a member of the Affected Community.

My qualifications, briefly, are as follows:

* California Registered Civil Engineer (16597)
* Fellow of the American Society of Civil Engineers
* Charter Member of the Association of Environmental Professionals
* Life Member of the American Water Works Association

My Class III sanitary landfill experience is as follows:

* Design and permitting manager at Emcon Associates for numerous landfills including the Kirby Canyon Landfill in San Jose, California
* Design and EIR involvement at Emcon Associates with respect to numerous landfills, including, Ox Mountain in San Mateo County, California (a BFI Landfill)
* Landfill Group Manager at Emcon Associates

* Design, permitting, and Operations Consultant for the Redwood landfill, Marin County, the Altamount landfill in Alameda County, and Kirby Canyon in San Jose

Currently I am employed by Santa Clara County as a professional engineer and have no conflict of interest in doing this review.

Please respond, with specificity, to the following comments:

A. Refer to Section 4.13-transportation/circulation; Page 4-346, passenger car equivalents (PCE) under Traffic Generation Criteria. It is stated that "one transfer truck is assumed to have approximately the same impact on normal traffic operations as three passenger cars, and one curb side collection trash truck is equivalent to two passenger cars". These assumptions appear to be understatements generally, and do not relate to the fact that the impact of a truck will vary significantly depending on the conditions of the road, e.g., a sloped entrance ramp, the conditions of traffic and signalization. 735

Please provide the following clarifications in response to this comment:

1. The source and precise conditions and data from which the assumptions were derived; 736

2. Supporting data that shows that the assumptions apply to each of the analyzed intersections; 737

3. Quantify the common occurrence of having multiple trucks occupy a short stretch of road and how that may produce impacts which are different than the assumptions. Note, experience shows that trucks neither enter nor leave landfills at an even spacing. Multiple trucks at an intersection, or even a stretch of road (for example where one truck attempts to pass another) can create much greater impact than an equal number of trucks evenly spaced out in traffic. 738

4. If the assumptions cannot be fully supported by data, they should be revised and the impact should be recalculated. 739

B. Please refer to page 4-372, table 4.13-9 (project specific mitigation measures).

1. The second paragraph where the San Fernando Road at Balboa does not provide a specific mitigation, but rather refers to a recommended traffic surveillance and an indication that preliminary discussion with LADOT staff indicate a computer signal control system with a possible mitigation that could be implemented. 740

Since a mitigation is supposed to be an inherent part of a proposed proposal project, on what basis can this be considered a mitigation? 741

2. Is there an absolute commitment that this mitigation will be provided? 742

3. If there is no assurance that the mitigation will be provided as part of the proposed project, the mitigation should be removed from the impact analysis. 743

C. Refer to page 4-44. Under City Mitigation Measures it is stated that "final maximum refuse slope, gradients shall be no more steeper than 2H to 1V for the landfill". 744

It is difficult to see how a 2H:1V slope can be considered a mitigation. Most landfills in earthquake prone areas in California are designed at 3H:1V or flatter.

There are a number of critical factors relating to slope stability that the Environmental Impact Report has not addressed. For example: 745

1. The contents of a landfill vary considerably throughout a given landfill. 2. The strength of any section of a landfill can change with time as decomposition (see page 2-65 "Refuse Decomposition Processes") and settlement takes place. 3. The contents of municipal landfills can be expected to change significantly with changes in technology, e.g., a paperless work place and with greater emphasis on recycling. 746 747

Given the many variables in trying to assess landfill performance, it is prudent to make conservative assumptions. It should be noted that an engineered fill (which is not the case here) is normally constructed with a maximum slope of 2:H to 1:V. An engineered fill uses graded and defined earth materials, moisture condition and compacted within narrow limits. By contrast, a sanitary landfill has a content which is to a large degree undetermined, which is loosely compacted, which is subject to significant settlement and changes in strength characteristics over time. These calculations are absent. Please state in your response to this comment how the stability analyses that have been conducted have reasonably considered the above variables. Also provide the basis for claiming that a 2H to 1:V slope is mitigation given that many experts including myself, would consider this an overly steep slope. 748 749 750

D. Refer to page 5.1. In considering potential sites for major new landfills, it is customary to perform a site selection study. Such a study uses a rigorous methodology which looks at all significant variables and (those normally cover by an EIR) within a geographic area. Additionally, the study evaluates acquisition 751

variables. There is no indication that such a study was performed in developing alternative sites for evaluation. Please respond to this comment by describing the methodologies (not the public processes which are described) used in selecting and analyzing the alternative sites. 752

E. Refer to page 5.4. Under section 5.3, "Methodology Used for Analyzing Alternatives," it is stated that "these alternatives were evaluated based on their ability to satisfy the specific objectives of the proposed project." This approach puts a major emphasis on the project proponent's stated development objectives and therefore shades the analysis in favor of their proposal. This approach does not appear to satisfy any reasonable standard for objectivity. Even referring to the project proponent's development objectives is misleading. Please describe what was done to insure objectivity given the project proponent's active participation in the alternative selections and the fact that these alternatives are evaluated by a consultant paid directly by the project proponent. 753

F. Section 2.10 page 2-75 states that the "combined landfilling at one face would consist of landfilling operation occurring on approximately 10 acres." This is a huge working face. Bulldozers, trucks, and other landfilling equipment will be operating from 5:00 a.m. to 6:00 p.m. dumping and spreading garbage on an area equal in size to about 15 football fields. The Environmental Impact Report describes litter control devices that will be employed to control the blowing of garbage. In the past litter control was a problem at Sunshine Canyon even with a smaller operation. 754

1. Describe what modeling or methodologies have been used to ensure the effectiveness or litter control.

What are the potential impacts of wind on the 10 acres that will constitute the working face with respect to garbage, dirt and air quality? What methodology, models and documents were relied upon? 755 756

OBJECTIVITY

As an individual who has been involved in the EIR process since its inception, it is obvious that even the most objective EIR consultants cannot maintain complete objectivity when they are working directly for a project proponent. Their interaction with the project proponent, their client, and their desire to maintain an ongoing relationship with that client, creates a major conflict for the consultant who is trying to be objective and professional. Additionally, the consultants often get caught up in their client's view of trying to deal with an unreasonable public and they use 757

their knowledge to craft an EIR which has an appearance, but not the reality, of objectivity. This is self evident in reviewing the Sunshine Canyon Environmental Impact Report. The above comments provide examples of advocacy of drafting the Environmental Impact Report in a manner to support the project rather being clearly objective. An additional problem is that the public must depend on the lead agency to identify statements in the Environmental Impact Report which lack objectivity. First an EIR of this scope and complexity is frequently beyond the review expertise of the agency staff. Secondly, the EIR can be crafted to deceive the reviewers.

Given the above, please describe exactly what has been done to ensure the objectivity of this EIR.

I look forward to the project proponent's detailed response to the foregoing.

Very truly yours,

LEONARD M. SALLE

RE: Sunshine Canyon Landfill

Dear Mr. Plafkin:

I along with my wife and two year old son, reside at 17457 Rushing Drive, Granada Hills, California 91344. My residence is situated in close proximity to the proposed expansion of Sunshine Canyon and I have the following questions with respect to the draft subsequent environmental impact report.

1. With respect to page 4-47, the Environmental Impact Report state that "on most spring and on early summer days, the daily air pollutants produced within the SCAB are moved out of the air basin through mountain passes or are lifted upwards by the warm vertical currents produced by the heating of mountain slopes. In those seasons, pollutants within the SCAB are disbursed and transported "often to a distance of sixty miles or more by ocean air currents during the afternoon." 758

a) What studies, methodologies, reports and/or documents are relied upon for this assertion?

b) What are the dispersion rates from carbon monoxide which is related to the proposed operation of Sunshine Canyon? 759

c) What are the dispersion rates from reactive organic gasses which is related to the proposed operation of Sunshine Canyon? 760

d) What are the dispersion rates from nitrogen oxide which is related to the proposed operation of Sunshine Canyon? 761

e) What are the dispersion rates from sulfur dioxide which is related to the proposed operation of Sunshine Canyon? 762

f) What are the dispersion rates from particulates which is related to the proposed operation of Sunshine Canyon? 763

g) What are the dispersion rates from fugitive dust which is related to the proposed operation of Sunshine Canyon? 764

h) What are the dispersion rates from ozone which is related to the proposed operation of Sunshine Canyon? 765

i) What are the dispersion rates from nitrogen dioxide which is related to the proposed operation of Sunshine Canyon? 766

2. With respect to the federal ozone standards discussed at page 4.53, the Environmental Impact Report states that these [ozone] concentrations increased during the summer, with daily concentrations increasing from the late morning to the afternoon. 767

a) How much ozone will be released during the summer months?

b) How much ozone will increase by each year? 768

c) What methods, studies and documents have you utilized to analyze this issue? 769

d) What will the affect of increased ozone have on the health of children in the affected area? 770

e) What will the affect of increased ozone have on elder people or people with respiratory problems in the affected area? 771

f) Have there been any studies done with respect to the increase of ozone over a localized area? 772

g) What, if any, attempts have there been made to mitigate the affects of increased ozone? 773

3. Have alternative sites been examined, as a possible mitigating factor? If so, please state the methodology used for analyzing alternative sites and all supporting documentation upon which the analysis was made. 774

4. What will be the affect of increased particulate matter on the population on the affected area? 775

5. What will be the specific health affect of increased particulate matter on the elderly? 776

a) Upon children aged 0-5? 777

b) On children aged 6-10?

c) On children aged 11-15?

d) On children aged 16-25?

6. What is the affect upon increased particulate matter on property values? 778

7. Has a modeling been done which examines levels of increased particulate matter as the usage of the landfill continues over time? 779

8. Have any studies been performed which examines the affect of increase particulate matter on the affected population? 780

a) If so what studies? If not, why not?

9. On page 4-55 the report states that "because the area is subject to frequent violations of both State and federal air quality standards for ozone and state standards for particulate matter the project area is very sensitive to additional ozone precursor and particulate pollutant emissions. 781

a) What, if anything, have been done to mitigate the affect of additional ozone and particulate matter in an area that is acknowledged to be an area "subject to frequent violations of both state and federal air quality standards for ozone and particulate matter"?

b) Exactly, what does it mean when Environmental Impact Report states that "the project area is very sensitive to additional ozone precursor and particulate pollutant emissions?" 782

c) What, if any, studies have been done in this area to ascertain the "sensitivity"? Are we talking about affects on people's health? This area must be addressed with specificity. 783

d) What studies if any, have been done to ascertain the effect of additional O3 and PM10 pollutants on the residential population which lives in the vicinity of the Sunshine Canyon? 784

e) If no studies have been performed, does BFI intend to perform any studies by a qualified health care professional prior to the expansion of Sunshine Canyon? 785

10. With respect to the table utilized on page 4-56 (table 4.2-2 "Air Quality Monitoring Summary for Santa Clarita Monitoring Station") the report notes that with the exception of inhalable particulates, all values are based on 365 days per year. 786

a) On what basis were the inhalable particulates measured?

b) Were the particulates analyzed by specific size? 787

c) If so, what methodology and documents were utilized? 788

d) Why is Sunshine Canyon being expanded when the report itself states that there will be an unavoidable adverse impact on air quality when Sunshine Canyon resides in an area that already has very poor air quality? 789

11. The Los Angeles Times in its November 20, 1997, edition reported a year long study by the Kaiser Foundation Research Institute which found a particularly strong correlation between hospital admissions and elevated levels of course particulates that typically come from road dust, tire wear and airborne erosion from construction sites. As indicated in the EIR, particulate matter along with other pollutants will rise significantly and the impact cannot be mitigated. Have the recent health studies (including Kaiser's) been reviewed, especially those concerning particulate matter, in relationship to the particulate matter that will be generated by Sunshine Canyon? 790

a) If yes, what studies have been reviewed? 791

b) If no studies have been reviewed that have specifically reviewed the relationship to the affects that particulate matter have on individuals, why is this project going forward? 792

12. The Environmental Impact Report fails to address the topic of potential diminution of property values. BFI has operated other municipal landfills in proximity to residential neighborhoods. 793

a) Have there been any studies which attempted to correlate the affect that the opening of a municipal landfill or the expansion of a municipal landfill has on residential property values?

b) If there have been any studies done, why were they not cited? 794

c) If there have been studies done, please specify the study, when it was performed and in relationship to which landfill? 795

d) If studies have not been performed, indicate why a study has not been performed which would demonstrate the impact, if any, the proposed expansion of Sunshine Canyon have on existing residential property values? 796

13. On Page 4.57 the Environmental Impact Report indicates that the Page Four SCAQMD is the first local agency in the country to adopt a market-based approach for controlling stationary source emissions of oxides of nitrogen and sulfur and, in accordance with the pending revisions, is proposing additional market-based control measures. 797

a) Does the Environmental Impact Report adopt a market based approach for evaluating air quality?

b) If a market-based approach is being adopted by BFI with respect to air quality, on what basis is it being implemented? 798

c) If a market based approach is being adopted by BFI with respect to air quality, how does the report relate to the health consequences of the residential population which resides adjacent to Sunshine Canyon? 799

14. The Environmental Impact Report, beginning Section 4.2.7 (site preparation/construction sequencing) provides a model for pollution. 800

a) Does the model show the variations from month to month and season to season?

b) If no, why not, especially since pollution levels are significantly higher in the summer months? 801

c) If yes, what model was used and what factual basis was used for the extrapolation? 802

15. Under 4.2.7, of the Environmental Impact Report further states that "based on the projected emission presented herein, a significant air quality impact is predicted for nitrogen oxide. 803

a) What levels will the nitrogen oxide increase to and how will those levels vary over months?

b) In addition, how will the increased levels of nitrogen oxide adversely affect the local residents? 804

c) Have health studies been performed to ascertain the health affects of the increased nitrogen oxide on the affected population? 805

d) If yes, what studies were done?

e) If no studies have been performed, is BFI going to perform any studies into the potential health affects on the subject population for increased nitrogen oxide prior to the opening of the expansion of Sunshine Canyon? 806

16. Why is the air quality monitoring a summary for Santa Clarita of monitoring station (table 4.2-2) only go through 1994? 807

17. In light of the fact that figures are available through 1996 wouldn't it not be more prudent for the Environmental Impact Report show the most current figures for the number of days standard for the exceeded maximum levels for monitoring such violations? 808

18. Based on the current Federal Clean Air Act requirements, how many days of the year will the PM10's exceed the federal standards for the proposed expansion? 809

19. Based on the current Federal Clean Air Act requirements, how many days of the year will the ozone exceed the federal standards for the proposed expansion? 810

20. Based on the current Federal Clean Air Act requirements, how many days of the year will the carbon monoxide exceed the federal standards for the proposed expansion? 811

21. Based on the current Federal Clean Air Act requirements, how many days of the year will the nitrogen dioxide exceed the federal standards for the proposed expansion? 812

22. Based on the current Federal Clean Air act requirements, how many days of the year will the sulfur dioxide exceed the federal standards for the proposed expansion? 813

23. Based on the current Federal Clean Air Act requirements, how many days of the year will the inhalable particulates exceed the federal standards for the proposed expansion? 814

24. What affect will the increase fugitive dust emissions have on the population adjacent to the Sunshine Canyon? 815

25. What studies have been done in relationship to the affect that fugitive dust emissions will have on the subject population? 816

26. Project construction is projected to produce nitrogen oxide (893.8 pounds per day) and PM10 (203.8 pounds per day) in excess of those levels deemed by the SCAQMD as significant. 817

a) What studies have been done to determine the health affects of the increased nitrogen oxide and PM10's?

b) What is the dispersion rate of the nitrogen oxides and PM10's? 818

c) What studies delineate the dispersion rates of the nitrogen oxides and PM10's? 819

d) If studies have not been done or reviewed which delineate the dispersion rates of the nitrogen oxides and PM10's why not? 820

27. At page 4-64 the Environmental Impact Report indicates an anticipated fuel consumption of 23.5 miles per gallon (which is comprised of transfer trucks, curb side collection trucks, and local delivery trucks). 821

a) Please identify the make and model of any transfer truck, curb side collection truck or local delivery truck that is able to obtain 23.5 miles per gallon.

b) please indicate the source of the calculations which were used to support the emissions estimated therein (it appears the calculations were based on an eight hour day as opposed to the ten hours of operational use which is indicated in the EIR). 822

28. On what basis was the conservative method utilized in the derivation of heavy equipment and vehicle emissions? 823

a) Would it be more appropriate to use a less conservative methodology? 824

29. Which respect to Fuel Storage and Dispensation, what are the calculations utilized to compute that daily diesel consumption for heavy equipment is estimated at 900 pounds per day. 825

30. Under Stock Pile Erosion (page 4-71) the report indicates that "At height of ten feet, a stockpile would require a land area of approximately thirty acres." 826

a) What is the height limitation on stockpiles?

b) What is the height limitation based upon? 827

c) How do the calculations of PM10's differ with respect to the height of the stockpile? 828

d) How many stockpiles could be utilized at any one time? 829

31. In the EIR's calculation on page 4-71, on what basis is .22 utilized for PM10 particulates? 830

a) What studies support the use of .22 for PM10 particulates? 831

32. With respect to the calculations shown on page 4-72 .36 is used for calculation of PM10 particulates. 832

a) On what basis is .36 utilized for PM10 particulates and what studies form the basis for utilizing .36 for said calculation?

33. In the carbon monoxide micro-scale analysis passenger car equivalents of 2 to 1 were used for curb side collection trucks and 3 to 1 were used for transfer trucks.

a) Is there any published documentation or studies on which justify or support such a conversion or ratio? 833

b) If such studies exist, please identify said studies.

34. With respect to page 4-76, which indicates that Screen Two model was utilized in the health risk analysis (4.2.9) which was not designed for a complex terrain such as Sunshine Canyon, why was such a model utilized? 834

a) How can you have accurate assessments of the health risks when the model utilized (Screen Model Two) is not designed for use in complex terrain such as Sunshine Canyon? 835

35. Has BFI studied the health risk associated with landfills in which a residential population is situated within a half mile of the landfill?

a) If yes, what have those studies revealed? 836

b) If no, why not consider the potential adverse consequences?

36. On page 4.77, the Environmental Impact Report indicates the chronic health impacts were predicated on conservative impact assumptions. Why are conservative impact assumptions utilized? 837

37. Under the Health Risk Analysis, was the health risk analyzed for the 9 carcinogenic material and the five noncarcinogenic constituents which were utilized in table 4.2-13. 838

a) If no, why were no such studies performed?

38. With respect to page 4-78 on the third indented paragraph the Environmental Impact Report that "the project environmental document should provide an analysis to demonstrate ... the project will not have significant negative impact on air quality in the long term (5 years or longer.) However, the next paragraphs states "the impact analysis demonstrates that significant levels of air pollutants will be generated over the long term." How does BFI square these two competing contentions? 839

39. The Environmental Impact Report further states that page 4-78 that "with resent finding by nationally recognized health experts, the new 1997 draft AQMP puts greater emphasis on PM10 particulate matter." Identify the recognized health experts identified in this statement as well as their reports. 840

40. If the air quality will be adversely impacted and cannot be mitigated, why are sites not thoroughly reviewed which are situated in an area which is not contiguous to a residential population? 841

41. With respect to the City of Los Angeles Air Quality Element, how is this project consistent with the goal of the obtainment of good air quality when the EIR admits that air quality will suffer and that the affects cannot be mitigated? 842

42. With respect to goal four listed on page 4-83 identify the "stand-alone health risk assessments". 843

a) What studies documents and/or research demonstrate that the "air pollutants admitted from the flare station, which is a pollution control device, was shown to induce no potential adverse health affects as indicated under goal four on page 4-83. 844

43. The Environmental Impact Report states that the "project is currently out of attainment for both ozone and PM10 suspends particulate pollutants." 845

a) Please identify how far out of attainment the project will be for O3 and PM10 for the life of the project and further indicate whether the project area will not be in attainment for other pollutants over the life of the project.

b) Further, specifically identify the methodology, assumptions, studies and documents, upon which the requested information is based. 846

44. As indicated on page 4-84 the project is considered significant on cumulative level with respect air pollutants. This being the case, on a year to year basis through the life of the project, identify how the amount of pollutants which will exceed the federal maximum standards. 847

a) Furthermore, identify the health risks associated with increased N02, S02, PM10, C0, ROG. 848

b) Furthermore, please identify the methodology, studies, experts and information utilized in arriving at said yet unstated conclusions. 849

45. What are the dispersion rates for N02, S02, PM10, C0, ROG, and at what distance do they meet the federal air quality standards? Please provide the documents, methodology, studies, which support the EIR, yet unstated conclusions, regarding these matters. 850

46. With reference to page 4-86, to what level will fugitive dust be mitigated? 851

47. On page 4-86, under the heading Exhaust Emissions, the report states that significant impacts are anticipated. Accordingly, what affect will the mitigation measures for heavy equipment and site construction have on the air quality? 852

a) What studies, if any, were performed to calculate the level of mitigation air quality? 853

b) To what degree will the air quality be mitigated by such mitigation measures set forth for heavy equipment operation and site construction? 854

48. With respect to page 4-87, how does the project proponent's commitment to reduce traffic congestion translate into the actual implementation of plan to reduce traffic congestion? Is the "commitment" legally binding on BIF? 855

49. With respect to table 4.2-15 (operational emissions, control measure reduction efficiency, and residual emissions), please describe how Ultrasystems Environmental Incorporated derived the numbers utilized in said table. 856

50. With respect to table 4.2-16, please describe the source of the numbers utilized by Ultrasystems Environmental Incorporated. 857

51. With respect to table 4.2-16, the EIR notes that control efficiency are conservative: On what basis are conservative control efficiencies utilized? 858

a) The EIR admits that in the past, the landfill was subject to prior dust control problems, how do the mitigation efforts used in the past differ from those that are planned to be used when Sunshine Canyon is expanded? 859

52. On page 4-91 the Environmental Impact Report states that "even with the implementation of mitigation measures, project-generated and project-related cumulative impacts are considered significant and unavoidable. The EIR appears to suggest that there will not be any health affects, this being the case, why are the impacts still considered "significant."? 860

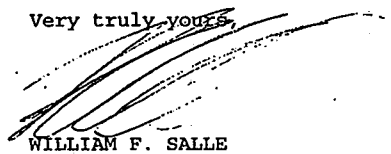
53. With respect to odor impacts, what studies, if any, have been done to support the EIR's claim there are formidable barriers to odor migration? 861

54. On what basis is the EIR's claim that the 1,700 foot separation between the nearest residential unit to the timber ridge is sufficient to eliminate potential odor nuisance problems emanating from the working face of the landfill. 862

55. With respect to the wind under 4.2.2 (California's SCAB regional climate characteristics report indicates "with very light average wind speeds, the SCAB's atmosphere has a limited capability to disperse their contaminates horizontally. It is common knowledge that average wind speeds do not reflect the extreme in wind variations and high winds often common in the hills surrounding Granada Hills. Especially, it is common knowledge that the winds can reach very high speeds in the canyon passes including, Sunshine Canyon. 863

a) Is it appropriate for the EIR to use a model that reflects the average wind speed? What methodology, models and documents were relied upon?

b) What is the dispersion of air contaminants horizontally during periods of high winds? What methodology, models and documents were relied upon? 864



c) What is the dispersion rate of air contaminants when they are disbursed with reference to various wind speeds? What methodology, models and documents were relied upon? 865

56. What affect will the air contamination caused by the project have on the LA Water Treatment Plant located off Balboa? What methodology, models and documents were relied upon? 866

a) Please provide the exact methodology and documents used to support any information on this matter.

I look forward to a detailed response to the very real concerns my family and I have with respect to BFI's proposed expansion of Sunshine Canyon.

Very truly yours,

WILLIAM F. SALLE

WFS/yh

RE: SUNSHINE CANYON LANDFILL PROJECT

Dear Hadar Plafkin,

I write not as a resident of Granada Hills alone, but as one who is very concerned about the environment as well. It appears that the biggest waste dump in LA, perhaps the world, is nearing a reality. 867

Big business and money probably have more clout than one more concerned citizen, but how can this be on the cusp on happening when, from the information I have received, there should be great alarm over the Final Environment Impact Report. What about that today, tomorrow? There appears dangerous potential for harm not to just those nearby, but to those much further away. What about us, our children? 868

A landfill of this monstrosity should not be located so near people and a fresh water supply. Seems common sense, let alone a formal report, should make that clear. 869

You have "the clout" of the opinion of one more concerned LA resident. 870

Sincerely,

George Kane

Re: Sunshine Canyon Landfill Expansion SEIR

Dear Sirs:

These comments are presented in addition to other comments submitted by our organization under separate cover.

We would like to begin by making some general remarks. We want to express concern that there is no material recovery facility planned in conjunction with this expansion. If we are really to re-direct our solid waste management policies, recovery facilities must be built. An existing landfill is an obvious and logical site as it would facilitate redirection of waste already arriving at the landfill and extend capacity. (We would not be supportive of an increase in daily tonnage to support a MRF as the daily tonnage approved for Sunshine is already substantial.) An industrial site away from residential areas would be even more suitable. This option should be explored. 871 872

The SEIR does not seem to adequately address air pollution problems that may impact the Santa Clarita Valley. Prevailing winds often produce "Newhall only" days of excessively high air pollution. The Santa Clarita Valley is designated as a non-attainment zone for compliance with ozone standards under the Clean Air Act. Landfills produce ozone precursors. These problems must be addressed and mitigated in the SEIR. 873

We object to "exempt waste" being calculated in such a fashion as to substantially increase the real amount of waste that is actually delivered to the landfill. It appears that the traffic and air pollution studies do not include this additional "exempt" waste delivery. This is a deficiency. 874

It seems that mitigations for impacts have changed between the County and City portions of the landfill. These changes sometimes appear in the text in locations that do not make them readily apparent. We request that the Planning Department prepare a table that identifies each County mitigation with a corresponding column for the comparable City required mitigation so that the decision makers may be informed as to the comprehensiveness and cohesiveness of the mitigation requirements for both areas. 875 876

Landfill Alternatives Save Environmental Resources

Water

Surface Water

The reports required for monitoring under the state General NPDES Permit and the General Industrial Stormwater Permit should be included in the appendices so that the decision makers and the public can make informed decisions regarding problems with control or pollution of surface water run-off from the landfill. 877

It has been stated in public scoping sessions and in the SEIR that the closed section of the Landfill will be covered by a liner and surface run-off diverted around this area. With the well-established settling phenomenon experienced by all landfills, we question the reliability of any liner that will undergo that much movement. The liner at Chiquita Canyon Landfill suffered a substantial tear from movement caused by the Northridge earthquake. It seems probable that a similar failure would be experienced by any liner subject to the stress of landfill settling. Also it was indicated that seam weld tests where only made to 30 PSI. Again, this does not seem adequate for the amount of stress that this liner would potentially incur. 878 879 880

Were surface water and flood flow controls analyzed for capacity to handle "El Nino" events? 881

Page 4-112 states that "The potential exists for non-stormwater discharges into the stormwater conveyance systems. Various measures would be used to separate stormwater from wastes being disposed of in the proposed landfill....". These measures should be formulated into a table for easy review and conditioned to be followed by the CUP. 882

Groundwater

Although there is a chart in the SEIR entitled "Site Ground Water Monitoring Wells Map" provided by GeoSynthetic Consultants indicating the location of Groundwater Monitoring Wells, Exploratory Borings/monitoring wells and lysimeters, there is no indication of the location of water quality data collected from leachate recovery wells, springs, surface streams and subdrains. It is therefore impossible for the public or the decision makers to determine if these samples were taken from downstream or upstream of the landfill and any hydrological movement of pollutants that may have occurred. This makes the data deficient for purposes of analysis. 883

23942 Lyons Avenue, Suite 103-353 • Newhall, CA 91321-2444 • (818) 845-7652

Printed on recycled paper

LASER

Landfill Alternatives Save Environmental Resources

Groundwater Data included in Appendix C18 is not comprehensive. Why was data included on surface streams only from 1995 to 1996 1st and 2nd quarter. Are these the required NPDES reports? Did the requirement begin in 1995? Page 4-129 states that "a comprehensive network of 22 groundwater monitoring wells was installed within Sunshine Canyon. Since installation, groundwater is sampled and analyzed quarterly for possible contamination." Why is data not included for monitoring wells other than CM-11 3rd Quarter, 1996? This is a deficiency. 884

Appendix C19 is entitled "DWP and MWD Water Quality Background Data". The data in this appendix refers only to imported water. Water quality of imported water would not be an indication of background quality of surface or ground water. Imported water has in fact no relation at all to the surface or ground water sources that might be impacted by the landfill and in no way can provide "background data". Was there any water quality information generated from the area of Sunshine Canyon prior to the original installation of the landfill? If so, this information should be included in the SEIR. 885

It is important for decision makers to note that a discussion of high chloride levels on page 4-129 discloses that the operator has been asked to do additional investigation to determine the sources of these elevated levels occurring downgradient of the landfill. Page 4-130 states that VOCs have been detected in one ground water monitoring well. Elevated Chlorides and VOC detection have been an indication of leachate leakage at other sites. These elevated levels could be an indication of pollutant migration within the ground water, an occurrence which the operator has denied could happen. Close attention should be paid to these points and all questions should be answered thoroughly to ensure the safety of the public. 886

Among the measures defined on page 4-134 to reduce leachate production is a statement that "Additionally, the proposed City/County Landfill will not accept liquid wastes or wastes with high moisture content." "High Moisture Content" should be defined by a percentage number, and this statement should be made part of the conditions of approval so that it is enforceable. 887

Section 4.3-.3 Flood Hazard/Mudflow Hazard - These hazards do not seem to have been addressed for El Nino events or the proposed greater height of the landfill. This is a deficiency. 888

Mr. Frank Meneses
Impact Analysis Section
Room 1354, Hall of Records
Los Angeles County Department of Regional Planning
320 West Temple Street
Los Angeles, California 90012

Dear Mr. Meneses:

Final Environmental Impact Report
Project Number SP 86312, Case 2556
Sunshine Canyon Landfill Expansion

We have reviewed the Final Environmental Impact Report (EIR) for the Sunshine Canyon Landfill Expansion. The comments herein represent Metropolitan's comments as a potentially affected public agency.

Request by the County Board of Supervisors

At its November 29, 1990 meeting, the Los Angeles County Board of Supervisors indicated that it would like to receive an official response from the Metropolitan Water District of Southern California regarding the Sunshine Canyon Landfill Expansion project's potential affect upon local water quality. Metropolitan believes the project would threaten local water quality if not properly designed and maintained.

The following factors, which are descriptive of modern municipal waste landfills, form the basis for Metropolitan's concerns:

* Waste deposited in landfills will contain household hazardous substances;
* Landfill wastes will not degrade into a benign state and will always have the potential for contamination until removed; and
* All lining systems are permeable and subject to leakage.

Metropolitan does not oppose the Sunshine Canyon Landfill Expansion. Metropolitan is concerned, however, that local water resources and conveyance systems be protected from contamination. The primary deterrents to contamination will be

Pg 3 of 4

The Metropolitan Water District of Southern California

California to deal with the regional water shortage situation. Although brackish water desalination technology has become technically and financially attractive in recent years allowing improved basin management strategies for brackish groundwater, such technology would probably not treat all landfill contaminants.

Existing Landfill Leakage

Metropolitan previously commented that contaminants may be leaking from the existing landfill and that this problem should be corrected before the landfill is expanded. We noted high chloride values observed at the down-gradient monitoring Well No. MW-1. Topical Response No. 9 (page 25) and Response No. 25 (page 91) of Volume A assert that the high chlorides are attributable to other sources, such as nearby oil drilling activities and natural geologic conditions. Metropolitan finds that the supporting arguments for Response No. 9 lack a straightforward technical analysis of the monitoring well data.

Because an understandable explanation of the high chloride values at Well No. 1, MW-1 is not provided, Metropolitan recommends that a comprehensive analysis of the monitoring well data be conducted and submitted to the Los Angeles Regional Water Quality Control Board (RWQCB) for its independent assessment of the leakage. If leakage is detected, the problem should be corrected before the subject expansion is approved.

Metropolitan has contacted the project engineers, Purcell, Rhodes and Associates. They have advised Metropolitan of plans to construct a gravel drain and pumping system to intercept potential leakage as part of the closure plan for the existing landfill. While this concept seems reasonable, we recommend that any doubts about leakage be resolved by the RWQCB through review of a report as suggested above.

Water Agency Coordination

Metropolitan's comments provided above have been coordinated with the the Los Angeles Department of Water Power and the Watermaster for the Upper Los Angeles River Area.

ATTACHMENT
LASER (Landfill Alternatives Save Environmental Resources) COMMENTS

1. Why, with solid waste alternatives available that can produce jobs across the labor spectrum, is the City willing to settle for an alternative that only generates 35 jobs at the project site? 890

2. Why are the County projections of landfill shortfalls used as a basis for this project any more credible now than they have been over the last 15-20 years, over which time history has shown them to be highly inaccurate? 891

3. Why is it considered more acceptable to offer a landfill proposal with a "buyback center," which is not conveniently located or efficient, in lieu of a full recycling facility without the landfill that can effectively reduce environmental impacts of solid waste disposal? 892

4. Why is hauling 11,000 tons of waste per day from all over the basin by trash truck to Sunshine Canyon considered to be more beneficial to air quality than centrally located waste processing facilities and waste reduction programs, with residues, if any, rail shipped to more remote sites? 893

5. What analyses have been done of the overall environmental impacts of the total City/County proposed project to support the contention that the substantial environmental impacts it poses will be less than using alternative disposal sites (e.g., desert sites) or technologies? 894

6. Why is using Sunshine Canyon for landfilling considered to facilitate implementation of A.B. 939 than use of solid waste technologies that don't require landfilling (A.B. 939's true objective) or using other sites with less proximity to population centers with less potential to be harmful to nearby residents? 895 896

7. How can an analysis that assumes Puente Hills will be filled in 2003 (when the County approved its expansion on a footprint that will last to or beyond 2013) and that Chiquita Canyon can only take 5,000 tpd (when the County approved it at 10,000 tpd) be considered anything but ultra conservative and biased toward approval of Sunshine Canyon? How does this analysis actually square with the reality of virtually no in-County impacts when BKK, Lopez Canyon, and Azusa all closed within a few months despite drastic projections of adverse impacts? 897 898

SUNSHINE CANYON LANDFILL EXPANSION
City of Los Angeles Jurisdiction
Environmental Impact Report Comments(Continued)
December 4, 1997

8. How can County DPW figures be relied upon to support landfill expansions when they are largely generated by L. A. County Sanitation Districts, who, with limited exceptions, is largely a landfill operator (Calabasas, Spadra, Puente Hills, Scholl Canyon, Savage Canyon), and strongly biases these figures to support their landfill operations? 899

9. How can conformity with solid waste management plans be listed as a compelling EIR basis for expanding Sunshine Canyon when environmental analysis of landfill expansion listed in those plans was not performed and left to individual site-specific evaluations at the time of expansion? 900

10. How can projected impacts of expansion of other landfills elsewhere in the county and outside the county be used as a basis for assuming that full expansion of Sunshine Canyon lessens regional impacts, when specifics of those alternative solutions are not identified? 901

11. How can expansion of Sunshine Canyon be judged environmentally superior on a regional basis to using non-landfill alternatives, which are being successfully used to eliminate landfilling in other jurisdictions, without a detailed analysis of those alternatives and how they could be used? 902

12. What back-up is provided for the assumption that non-landfill alternatives cannot resolve the need for disposal capacity? How can this analysis be considered complete without citing examples of locations where techniques like landfill mining and recovery are actually being done to not only eliminate current landfilling but reduce the volume of environmentally hazardous landfills? 903

13. How can inconsistency with project objectives be used as a basis for eliminating non-landfill solutions when, in fact, those objectives were specifically established by landfill proponents, including the project proponent, to support landfill expansion? 904

14. Why is disturbance of desert sites, which represents a far greater habitat resource than native habitat in Los Angeles County canyons, considered to be a greater environmental impact than full development of Sunshine Canyon, particularly for a site like Eagle Mountain where existing terrain has been heavily disturbed by open pit mining? Does this statement also consider the number of residents adjacent to the Sunshine Canyon site and to the desert sites? 905 906

15. How can the proponent automatically assume that if the City of Los Angeles finds the environmental impacts of expansion of Sunshine Canyon to be unacceptable that the County expansion will still be allowed, so the environmental benefits of not allowing the City expansion will be minimal? 907

SUNSHINE CANYON LANDFILL EXPANSION
City of Los Angeles Jurisdiction
Environmental Impact Report Comments(Continued)
December 4, 1997

16. Why aren't the cumulative impacts of disposal at Chiquita Canyon, Elsmere Canyon, and Sunshine Canyon considered together, since these projects are not mutually exclusive? How can this inconsistency be justified in light of the reality of what might be projected to happen if the premise that all four near-term landfill closures cited in the document as one of the bases for this expansion actually occurred? 908

17. Why is there no in-depth analysis of use of non-polluting waste-to-energy technologies, volume-based disposal fee structures, in-vessel composting, and other technologies that both provide economic benefit through resource recovery and job creation, as well as eliminate of adverse landfill impacts. 909

18. How can cost be used as a major basis for eliminating consideration of the Reduced Volume Alternative when no economic analysis is provided and CEQA does not allow cost to be used as a basis to eliminate environmentally superior alternatives? 910

19. How can destruction of California Gnatcatcher habitat be considered consistent with guidelines which site the importance of habitat preservation as a key objective of preserving sensitive species? Are Gnatcatcher surveys to be conducted systematically. or simply by casual field observation on site visits, which does not conclusively demonstrate that rare species are not present? 911 912

20. What permit requirements will be imposed to assure that odor and associated harmful gas migration will be properly mitigated if such impacts prove to be more of an operational problem than the EIR anticipates? Experience at other landfills demonstrates that the proposed mitigation measures described here are not effective. 913

21. Will the permit include requirements for conformance to the level of significance used by the City as a basis for approval, if approved, with possible cessation of activities if proposed mitigation measures are not effective in bringing landfill operations into conformance with EIR commitments in areas like traffic impacts, odors or release of other harmful gases, seismic slope stability, ground water contaminant leakage, dust, and litter? 914

22. Since replacement habitat plans are not yet available for review, will opportunities be provided under a formal City process for interested residents to participate with public agencies in assuring that these replacement plans are truly effective? Will destruction of on-site sensitive natural areas, including trees, riparian habitats, and other significant resources, be prevented until such time as agreement is reached that replacement plans are truly equivalent? 915 916

SUNSHINE CANYON LANDFILL EXPANSION
City of Los Angeles Jurisdiction
Environmental Impact Report Comments(Continued)
December 4, 1997

23. Will landfill activities be reviewed during operations by a Citizens Advisory Committee composed of resident representatives including LASER member North Valley Coalition? Will members of this group be granted opportunity for actual on-site verification of conditions described to them at meetings? It is assumed that notification for such visits should require no more than 24 hours and should be subject to denial only if conditions exist that would compromise their safety. 917 918 919

Attention: Hadar Plafkin, City Planner

I am writing to comment on the B.F.I. "E.I.R." report prepared in regard to opening the City portion of the Sunshine Canyon Dump. First I have difficulty with the objectivity of an E.I.R. report bought and paid for by the company that wants to create something that is obviously an environmental disaster. I would also be interested in learning how such a self-serving and biased system of doing "your own" E.I.R. reports was ever allowed. 920

That said, I have some other problems with B.F.I's "E.I.R." report. There is no mention in the E.I.R. of how home owners will be compensated for the loss of value of our property if this huge dump is permitted to open. It does mention the revenue the City Of Los Angeles will receive, conveniently omits the revenue B.F.I. will receive and makes no mention of the revenue losses property owners will "receive." 921 922

Why is this dump even being considered? The City closed it once because it caused such problems in our neighborhood. Why, in B.F.I.'s E.I.R. report is every alternate sight including sights that are not that distant, can accept more garbage for many more years and are located away from residential areas always somehow found to be environmentaliy less acceptable, except when it comes to "humans" living next to this location? Is it because B.F.I. doesn't own these other locations? 923 924

I'm concerned with this E.I.R.'s apparent dismissal of any earthquake danger in the dump. To say the faults in the canyon are inactive is a rather careless assumption. The Northridge "Fault" was not only "inactive", it wasn't even known to exist. Also to say the dump can withstand a "direct-hit" equal to the Northridge quake is at best speculation and at worst careless. This carelessness not only endangers the people who live close to the dump but if the dump doesn't withstand the "direct-hit" and tons of garbage end up in the nearby City water facilities it will effect thousands of others, too. 925

In the very few instances that the B.F.I. E.I.R. report even admits there are "adverse" effects on our community, from this dump, there is no suggestion what might be done to alleviate these adverse effects. Is it just..."too bad, folks?' 926

With approximately 1000 trucks dumping garbage everyday what besides telling private haulers they can't dump their loads of garbage if their trucks are emitting excessive smoke what will be done? Will City owned trucks be told the same thing or will they receive a "pass?" Also, what besides "encouraging" small commercial and private users of the dump not to use Balboa Blvd., will prevent these operators from totally taking over Balboa Blvd., to get to the dump? 927 928

I would also like to express concern that another huge brush fire similar to the 1989 Granada Hills fire could start in the middle of the night in the Dump. Although B.F.I. denies the fire started in their dump, it was never said to have started anywhere else either. 929

In B.F.I.'s E.I.R. report it mentions at some point entire operation of the dump will be visible by motorists driving Northbound on the I-5 freeway. What, if any, thought has been given to the danger of distracting drivers and what about the possibility of the considerable wind that blows in the area blowing debris onto the I-5? 930

Finally, although I have other concerns I would like to emphatically state that there was horrible dust and debris from the old, now finally closed, city portion of the dump. In the B.F.I. E.I.R. report it is stated that during the often windy periods they will water down the garbage. A few years ago while preparing the hills at the end of Jolette Avenue to build houses during the grading work the contractor watered down the dirt. Believe me during 90 degree heat with the wind blowing the dust wasn't abated and this was just "dust/dirt" not dirt full of pollution, germs and other filth generated by garbage. 931

Even in B.F.I.'s own E.I.R. report they have to admit that there would be much less environmental damage if they confined their operation to only the Canyon portion. 932

They do point out they'll have cut down another 1300 Oak trees in addition to the 2700 they've already chopped down if they're not permitted to reopen the City portion of the dump. While I'm not in favor of the dump at all and not in favor of chopping down another 1300 Oak trees I would prefer the cutting down of trees as opposed to the cutting down of human beings especially children which this "Mega-Dump" could very well accomplish. At the recent B.F.I. "Key Group Meeting" I couldn't find one B.F.I. employee that lived in our neighborhood. Perhaps we could get an answer why. 933 934

Sincerely

Thomas K. Murphy

Pollution linked to hospital stays

Close connection of smog, illness alarms activists

By David R. Baker
Daily News Staff Writer

As smog and soot levels rise in the Los Angeles air, so do hospital admissions for asthma, pneumonia and other respiratory problems, a new study found.

The study, to be released today at an air-quality symposium, tied daily air pollution measurements to patient admissions during 1995 at Kaiser Permanente hospitals, including those in Woodland Hills and Panorama City.

Researchers found that the number of admissions rose in lock step with increases in either ozone levels or the amount of particulates — airborne pollutants far smaller than the diameter of a human hair.

"This is the first study of its kind conducted in the (Los Angeles) Basin and shows that the region's air pollution continues to be a leading public health concern," said Shankar Prasad, health effects officer for the South Coast Air Quality Management District, which paid for the $145,000 study.

Although researchers expected to see some correlation between pollution and hospital admissions, they didn't expect such a significant increase, said district spokesman Sam Atwood.

The study comes just after the AQMD announced the region experienced the least-smoggy season on record.

Local environmentalists called the findings alarming.

"These are people hospitalized simply because they were breathing the air, not because they were doing anything harmful," said Tim Carmichael of the Coalition for Clean Air. "It's a tragic situation, and we've got to do everything we can to change that."

Indeed, the study and the symposium — hosted by the air quality agency — could have far-reaching effects on how Southern California deals with air pollution. After listening to the results of this and other health studies today, participants in the two-day symposium will discuss efforts to cut emissions from what many consider a major source of air pollution — diesel engines.

Although only 4 percent of California vehicles use diesel, those vehicles account for more than 30 percent of nitrogen oxide emissions and even more of the particulate pollution, according to the AQMD.

Two bills that would encourage truck-fleet operators and others to switch from diesel-burning engines were discussed in the state Legislature during the past session. And next year, the state's Air Resources Board will consider listing diesel exhaust as a toxic air contaminant, a step that could lead to further regulation.

Beau Biller, spokesman for the California Trucking Association, said he opposes such a classification because it would leave diesel users vulnerable to lawsuits from people claiming the exhaust made them sick.

The Kaiser study did not look at specific sources of pollution. Instead, it matched ozone levels and particulate emissions throughout 1995 with Kaiser records covering 1.6 million patients.

For every 10 microgram increase in the concentration of particulates, hospital admissions rose an average of 7 percent for chronic respiratory illnesses, 3 percent for cardiovascular disease and 3.5 percent for acute respiratory illnesses.

Ozone had a similarly hazardous effect. During the study, when the ozone concentration in the air rose by 10 parts per billion, an average of 2.7 percent more people with chronic respiratory problems, 5.7 percent more cardiovascular disease sufferers and 1.5 percent more people with acute respiratory diseases checked themselves into the hospital.

Re: Proposed Sunshine Canyon Landfill Expansion

I am writing in response to the Sunshine Canyon Landfill Expansion Environmental Impact Report. Following are the questions and/or comments about the EIR.

In addressing the Alternatives to the proposed project, Section 5.0 of the EIR, states that an EIR must "describe a range of reasonable alternatives to the project or to the location of the project, which would feasibly attain most of the basic objectives of the project but would **avoid or substantially lessen any of the significant effects of the project, and evaluate the comparative merits of the alternatives.**" The difficulty is in evaluating the comparative merits of the alternatives, particularly when we have a County and City believing that we are facing an imminent "time to crisis". As we run around in circles, arms flailing in the air above our heads close to panic, we fail to see that the alternative to landfilling in one area is not to landfill in another. The EIR pits one potential landfill site against the other, all with similar significant impacts. The "viable" alternatives are all landfills with the same objectives as the proposed project therefore not fitting the strict definition of an "alternative." Of the eight (8) "alternatives" analyzed only the subsection Waste-to-Energy under Waste Management Technologies and Strategies is strictly an alternative. The others under that same section are waste diversions. The EIR fails to address and evaluate **non-landfill disposal** alternatives. Why were these alternatives not addressed? 935 936 937

The EIR also states that "feasible is defined in the CEQA statutes (21061.1) as 'capable of being accomplished in a successful manner within a reasonable period of time, taking into account economic, environmental, social and technological factors.'" At this point in time, there have been 2 documents produced that address these factors directly. Both are included for the record. The first document, **Approaching an Integrated Solid Waste Management System for Los Angeles County, California,** defines how the County and thereby the City can implement certain scenarios with waste diversion and recycling that, I believe, will give us the period of time to address the economic, environmental, social and technological factors of feasible, viable alternatives. **(Figure E-1, Page E-4)** The **Solid Waste Task Force Report** gives us an introduction to those alternatives. 938 939

The fact that the proponent is requesting a permit for the proposed project, an Immediate 940

Combined City/County Landfill Operation, leads me to believe that the following discourse and and the submission to the record of these documents is relevant.

GBB Solid Waste Management Consultants, the producer of the report entitled "Approaching an Integrated Solid Waste Management System for Los Angeles County, California" states the objectives of the report on **page E2:** 941

1. To offer **alternatives** to the Board of Supervisors and the public for urban landfills.
2. To provide suggestions for **extending the life of existing landfills.**
3. To foster a policy consistent with AB 939 to **divert** solid waste away from landfills.

GBB depended on the 1996 Siting Element and the 1995 Draft Environmental Impact Report/Draft Environmental Impact Statement for Elsmere Canyon to arrive at their suggestions. The County also "relied on these two documents to sustain their current landfill policy." 942

According to GBB **"A review of the County's reports reveal that they exaggerated the projection of waste generation and the need for additional landfill capacity. When critically analyzed, there is a clear discrepancy between the two documents regarding the amount of waste generated per day. The Siting Element projects waste generation per day for 1997 to be some 4,200 tons more than the DEIR/DEIS document. The County has employed the higher estimate presented in the Siting Element document, thus accelerating their claim that additional new landfill capacity is required or the "time to crisis" is imminent." (Page E-3)** In November of 1993 when the proponent (BFI) asked and eventually received a permit to expand into the County portion, Dr. Gerald Simmons arrived at the same conclusions as GBB. The County gave an overriding consideration to the expansion because of the "time to crisis" phenomenon. All based on exaggerated figures.) 943 944

From the evaluation and analyzation of the Siting Element and the DEIR/DEIS , GBB presents a strategic approach to addressing the County's short term 15 year "time to crisis" by "selecting a series of **proven low risk alternatives**" which will enable the "County to develop waste disposal policy well beyond the AB 939 planning period." 945

In order for the County to accomplish its long term goal a set of Scenarios are proposed that can operate independent of one another or combined to have a cumulative impact. These same scenarios, I believe, can be applied to the City. 946

" Scenarios 1-6 is relatively **low cost** and politically risk-free compared to the cost of landfill expansion." **(Figure E-1, Page E-4).** If these scenarios were to be utilized, **24 years of capacity could be realized, thus giving the County and the City ample time to address and implement viable alternatives.** 947

The viable alternatives are presented to us in a report by the Solid Waste Task Force in conjunction with a Technical Advisory Group. They address recycling and diversion but they go one step further and address alternatives to landfills, not alternative landfills to landfills.. Although the information is not detailed nor do they in some instances look at costs, nonetheless they introduce alternatives some of which should have been addressed in the EIR. (Enclosed for 948

the record-11/7/97 Draft, Section 3.0, Page 9.)

Given that we have two documents that will enable the County and the City to make a beneficial change in the policies and procedures of solid waste management, that diversion and recycling will give us 20 odd years to explore alternatives without the need of further expansion or new landfills, I would like to request an evaluation of the Scenarios introduced and addressed in the GBB document and an evaluation of the alternatives presented in the Solid Waste Task Force Document before permitting the Combined City/County Operation for Browning Ferris Industries. 949

Questions:

Section 5.4-There were ten major Class III landfill facilities as of January 1996, since then 3 have closed. Figure 5.4-1 shows 8. Three from ten is 7...? 950

Section 5.4 page 5-9 When other in-County landfills exhaust their capacities and close, won't the increased reliance on the existing landfill (if permitted) Combined City/County Landfill at Sunshine Canyon experience the same increase of environmental impacts to a level of greater significance? 951

Section 5.4 page 5-9 How can there occur rapid depletion of the County's long-term landfill disposal capacity if the County's goal is toward recycling and diversion? 952

The Immediate Combined City/County landfill will be the new kid on the block. Won't the increased reliance be placed on the proposed project facility due to landfill closures, thereby increasing environmental impacts to significant levels at that facility? 953 Are we to assume that this landfill will not import trash, nor will the other landfills exhaust their capacity making it unlikely that that waste stream will be diverted to Sunshine Canyon? 954

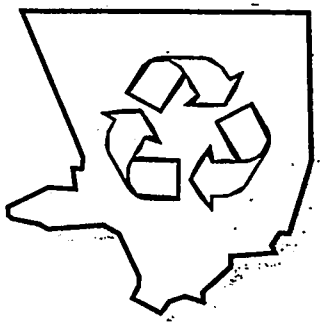
The burden of providing disposal capacity at Sunshine Canyon will create local significant impacts. How do you justify placing that burden on local over remote locations when you factor in the population quotient in close proximity to the landfill? 955

The Immediate Combined City/County Landfill Operations will have greater significant impacts after the first 18-24 months. What will those impacts be? 956

In conclusion, the responsibility of permitting landfills falls squarely on the shoulders of the agencies making the decisions. It is to these agencies that the Council looks for guidance in making its decisions. This holds true for the County as well. By assuming that position of authority the agencies must look at and take into consideration all the factors at work in a project. When we speak of significant impacts, we are talking about children, the elderly, the ill and all others in between. 957

If economics is the driving force for the permitting of these necessary landfills, then the long term economic effect on the residents closest to the project must be evaluated. This would include property, health and livelyhood. 958 If the EIR addresses to "reduce the project proponent's long-term capital outlay for site infrastructure" then the EIR must also address the long-term capital outlay for the residents that will be significantly impacted by this landfill. 959 You cannot make an informed decision in a vacuum. All factors must be considered. The long-term capital outlay for the residents of the area will far exceed that of BFI for their infrastructure when there

are consistent impacts of a significant nature to the resident's that, by BFI's own admission, cannot be mitigated to a non-significant level. That admission can be found under the Section of Air Quality in the EIR.



We are looking at increased health problems over the long-term caused by the existence of a landfill in close proximity to a residential area as opposed to health and safety problems caused by the lack of landfill capacity. 960 Which in your determination, in the long-term is easier and more cost effective for a County or City to resolve? 961 By first evaluating and implementing a strict diversion and recycling program the County and the City will increase the period of time needed to evaluate cost-effective alternatives that will not produce the significant impact that the proponent of this landfill admits cannot be mitigated. 962 Serious consideration must be given to the proposals stated in this letter before permitting the project site. 963

Thank you for your time.

Sincerely,

Encl.

Approaching an Integrated Solid Waste Management System for Los Angeles County, California

APPROACHING AN INTEGRATED SOLID WASTE MANAGEMENT SYSTEM FOR LOS ANGELES COUNTY, CALIFORNIA

EXECUTIVE SUMMARY

Throughout the nation there is growing controversy regarding the best approach for managing the millions of tons of waste generated by residents, businesses, and industries in large urban areas.

Pressures from both the public and private sectors have been successful in focusing attention on recycling and other alternative methods for managing of solid waste. As a result, a number of new statutes throughout the nation have been enacted to minimize reliance on landfills. California adopted Assembly Bill 939 (AB 939), the California Integrated Waste Management Act, in 1989. This act mandated that by 1995, 25% of the waste stream in each of California's counties had to be diverted from landfills. Furthermore, the act required that this diversion rate be increased to 50% by the year 2000. Diversion is defined as the process of diverting solid waste away from landfills through source reduction, recycling, and composting.

One year prior to enactment of AB 939, Los Angeles County developed a Solid Waste Management Action Plan (1988) which explicitly called for 50 years of in-county landfill capacity and minimized diversion potential. Six new in-county landfills were proposed in this Action Plan. In spite of the new legislative mandate to increase diversion of waste from landfills, as well as rapidly advancing technology which enabled the capacity of existing landfills to be expanded, Los Angeles County persisted in emphasizing landfills as the primary means of solid waste disposal.

Clearly an independent analysis of Los Angeles County's public policy on solid waste disposal was needed. This report provides another perspective to a "landfills first" policy, based upon carefully studied data projected in alternative "scenarios" by the authors. The Board of Supervisors could consider this document in their decision making process to comply with AB 939, as well as to preserve urban land for alternative uses.

These scenarios describe how Los Angeles County can implement strategies to increase regional interest. The goal is to divert more than 50% of the County's trash away from urban land and add years to the final life of the existing landfills in the County.

WHAT ARE THE OBJECTIVES OF THIS REPORT?

1. To offer alternatives to the Board of Supervisors and the public for urban landfills.
2. To provide suggestions for extending the life of existing landfills.
3. To foster a policy consistent with AB 939 to divert solid waste away from landfills.

Thiis report paints a different picture of the future of solid waste disposal by making the following points:

- The document presents a strategic approach for addressing short and long term solid waste disposal requirements. The key to implementing the approach involves selecting the appropriate combination of alternative scenarios.
- By selecting a series of proven low risk alternatives (such as shown in Scenarios 1-5) for immediate implementation, the County's short term 15 year "time to crisis" is alleviated.
- Adoption and implementation of additional policy alternatives as recommended in the report enables the County to develop waste disposal policy well beyond the AB 939 planning period.

WHY DOES THE COUNTY DRAW DIFFERENT CONCLUSIONS FROM THE SAME DATA?

To illustrate the potential impact of creating a new diversion policy in Los Angeles County, the authors of this report developed a computer model which allocated the waste generated in the County among diversion and alternate disposal options. Prior to developing a model, the report presents a comprehensive review of two County sponsored documents; the 1996 Siting Element and the 1995 Draft Environmental Impact Report/Draft Environmental

Impact Statement (DEIR/DEIS) for Elsmere Canyon. The County has relied upon these two documents to sustain their current landfill policy.

A review of the County's reports reveal that they exaggerated the projection of waste generation and the need for additional landfill capacity. When critically analyzed, there is a clear discrepancy between the two documents regarding the amount of waste generated per day.

The Siting Element projects waste generation per day for 1997 to be some 4,200 tons more than the DEIR/DEIS document. The County has employed the higher estimate presented in the Siting Element document, thus accelerating their claim that additional new landfill capacity is required or the "time to crisis" is imminent. The computer model projects the quantity of waste disposed of in landfills located in Los Angeles County beginning in 1996 and running through 2044. The model evaluates waste disposal through the use of a series of waste management strategy scenarios. Each scenario develops a series of diversion alternatives aimed at increasing the life of in-county landfills.

SCENARIOS

The following summarizes the seven computer generated scenarios found in this report. Each scenario provides waste management strategies aimed at diversion such as recycling and composting, which will ultimately increase the life of existing in-county landfills. These scenarios can operate independent of one another, but in the analysis Scenarios 1-5 have been combined to have a cumulative impact. The impacts of the scenarios are shown graphically in Figure E-1.

SCENARIO 1--HISTORIC RATES

The County's solid waste strategy found in its Siting Element, the Base Case, calls for a minimum diversion of 50% as required by AB 939 and disposing the remaining waste in landfills.

Scenario	Waste Diversion and Disposal Policies	Projected Landfill Shortfall Date (Cumulative)	Years Added to Landfill Capacity
Base-Case	LA County Public Works' latest baseline for waste generation, rate of landfill use, and recycling (50% only from 2000), found in the Siting Element.	1999	N/A
1	The County's latest base-case with the historic use (daily disposal) rate of landfills, not the theoretical maximum rate.	2001	2
2	Include a net waste export of waste to Orange County landfills (which began January 1996) of 3,500 tons per day in 1997; rising to 6,000 in 2001 through 2026.	2007	6
3	Increase recycling of inert materials like construction and demolition debris (C&D), and divert remainder to the proper inert materials landfills, and away from Class III landfills from 1996.	2009	2
4	Incorporate the impact of LA City for 70% waste diversion (recycling, composting) by 2020 for the County Unincorporated areas as well as LA City.	2010	1
5	Use space-saving chemical/foam cover instead of dirt as the cover added daily to landfills, on all LA County landfills from 1997.	2014	4
In addition to Scenario 5, one or both of the following:			
6A	Intensive diversion and recycling: adopt and implement the 70% waste diversion rate by 2020 for all of LA County and its 88 cities (residential, commercial, industrial).	2016	2
6B	Intensive diversion and recycling: add a ban on recyclable materials -- wood, corrugated paper and yard waste -- from landfills starting in 1998.	2019	5

	Effect of Additional Policies:	Years Added to Scenario 5
7	Assume no increased waste diversion, but expand five of the existing landfills to around half the level proposed by the County; no new landfills.	6
--	Use the conservative waste generation growth projections based on accurate, LA County specific data.	3

Figure E-1. Summary of Policy Options to Increase Diversion and Provide Adequate Disposal Capacity for Los Angeles County

Contrary to the County Siting Element figures which overestimates by using Daily Permitted Capacity numbers, this scenario utilizes more realistic figures based on a landfill's historic usage. This recalculation delays the supposed Daily Disposal Capacity Shortfall or "time to crisis" until the year 2001, two years past the County's original estimate (2 years).

SCENARIO 2–EXPORT ADDITION

The County's Siting Element does not account for existing export of L.A. County waste to Orange County. This scenario accounts for this export at a rate of 2,000 Tons Per Day (TPD) based on existing contracts in 1996 and 3,500 TPD starting in 1997. Exports are raised to 6,000 TPD in the years 2001 through 2044. Thus, this scenario extends the time to crisis from 2001 to 2007 (6 years).

SCENARIO 3–INERT MATERIAL AND BIOSOLIDS BAN

This scenario would ban inert materials and biosolids (sludge) in Class III landfills. It is assumed that the inert ban would be 80% effective and the sludge ban 100% effective since the material is controlled by the County. If implemented, this scenario extends the time to crisis to the year 2009 (2 years).

SCENARIO 4–DIVERSION GOAL BY 70 PERCENT

This scenario calls for the County to join with the City of Los Angeles and adopt a goal of 70% diversion in all unincorporated County areas by the year 2020. The result would be an extension of Daily Disposal Shortfall (time to crisis) to 2010 (1 year).

SCENARIO 5–CHEMICAL/FOAM COVER

This scenario replaces the use of dirt to cover waste deposited daily in L.A. County landfills with a chemical or foam cover. The report assumes a daily foam or chemical cover is initiated in 1997. The saving capacity is 22%, allowing space for 22% more waste at each

landfill. Implementation of this technology will delay the Daily Disposal Shortfall until the year 2014 (4 years).

SCENARIO 6–INTENSIVE RECYCLING AND DIVERSION

Two different model scenarios were conducted, both of which are mutually exclusive to the other.

6a. Total County 70% Diversion. Assumes all cities and the unincorporated areas of Los Angeles County achieve 70% diversion by 2020. Starting in 2001, the impact would increase diversion by one percent per year, extending the shortfall to the year 2016 (2 years).

6b. Recyclable Material Ban. Assumes a ban of corrugated wood and yard waste in Class III landfills beginning in 1996. The ban would be 70% effective and postpones the Daily Disposal Shortfall until 2019 (5 years).

SCENARIO 7–LANDFILL EXPANSION

This scenario was added not to propose landfill expansion but to put in proper context for policy makers the comparative results achieved by focusing on a reduce/recycle/compost strategy. Implementing Scenarios 1-6 is relatively low cost and politically risk-free compared to the cost of landfill expansion. It also illustrates that 24 years of capacity can be realized by these methods. Further ample time is realized for emerging alternatives such as rail haul to take effect and further alleviate the pressure for landfilling of waste within the County. This strategy must be enacted in conjunction with Scenarios 1-5 to postpone the Daily Disposal Shortfall until 2023 (9 years).

HOW CAN LOS ANGELES COUNTY CREATE AN ALTERNATIVE WASTE DISPOSAL POLICY?

In this report a number of different alternatives to extend existing landfill capacity are examined. Clearly, if the County adopts these alternative strategies there is no need to develop

new landfills anytime in the near future. In order to implement these alternatives Los Angeles County will have to shift its waste management strategy and place more emphasis on recycling and diversion *as required by law.* Further, the County should realize that its self-imposed requirement of 50 years in-county disposal capacity may have a serious legal flaw. The courts have recently ruled in-county disposal unconstitutional.

The first step is for the County to develop a new policy which outlines the process of diverting solid waste away from landfills through source reduction, recycling and composting. Once the policy is adopted, the County will become responsible for implementing and ensuring the process of diversion. Specifically, the County should:

- Develop a diversion strategy;
- Adopt billing and accounting methods for solid waste that fully account for all cost items;
- Set new diversion goals for the County's unincorporated areas, and to monitor and report on the achievement of these goals;
- Coordinate and facilitate diversion programs with the County's 88 municipalities;
- Provide incentives between the public and private sectors to increase the participation in County-wide diversion programs; and,
- Function as a role model to the cities by developing a model recycling program for all County facilities, as well as implementing a County-wide "reduce-recycle" advertising campaign.
- Review legality of flow control ordinances or other restrictions on waste flow in the County.
- Develop detailed costs for implementation of the new policy.[1]

[1]Detailed cost analysis of diversion options was beyond the scope of this study.

CONCLUSION

It is the conclusion of this report that Los Angeles County can effectively meet and exceed its AB 939 requirements without opening new landfills. Indeed, by leading its 88 municipalities and the unincorporated areas into the 21st century, Los Angeles County can be the facilitator to implement an effective regional diversion-oriented solid waste disposal policy. However, the County must act now.

I. INTRODUCTION AND PURPOSE

The impetus for the development of this document arises from sincere concerns about the potential environmental, aesthetic, and social consequences of Los Angeles County's policy of developing in-county landfills for solid waste management. The County's promotion of the new Blind, Elsmere Mission/Rustic-Sullivan and Towsley Canyon landfills provides examples of this. The authors and many individuals and groups in the County feel strongly that there are better ways of managing the rubbish of our society than vast storage piles that must be engineered, managed, and monitored for 80 to 100 years, and, in the process, destroying pristine canyons with their wildlife, waterfalls, and opportunity for open space recreation in an increasingly urbanized area. The alternative vision is a diversion-based policy that applies the full array of modern solid waste management technologies that together can reduce, reuse, and recycle as much of the solid waste generated by the residents and businesses in the County and the 88 cities as possible, and transform or safely dispose of the remainder.

Approaching an Integrated Solid Waste Management Plan for Los Angeles County was prepared by Gershman, Brickner & Bratton, Inc. (GBB), a national consulting firm that specializes exclusively in solid waste management. GBB's professional staff consists of engineers, planners, economists, environmental scientists, market analysts, and recycling and community relations specialists. GBB was assisted in this effort by a distinguished team of individuals who provided unique perspectives on Los Angeles County issues. They are:

- Joan Edwards, of J. Edwards & Associates, former Director of the Integrated Solid Waste Management Office for the City of Los Angeles Board of Public Works.
- Eugene Tseng of E. Tseng & Associates, a nationally-recognized environmental engineer and member of the California bar who has provided technical services to the State of California as well as technical oversight for the City of Los Angeles' AB 939 Solid Waste Generation Study. Eugene Tseng is also an Adjunct Professor at the UCLA Anderson Graduate School of Management.
- J. Eugene Grigsby, III and Leobardo F. Estrada of UCLA. Eugene Grigsby is president of The Planning Group in Los Angeles. He is also a professor at UCLA's Graduate School of Public Policy and Social Research, where Leo Estrada is an associate professor. Dr. Grigsby and Dr. Estrada provided essential population and demographics data for Los Angeles County.

It is not intended that this document serve as a detailed Integrated Solid Waste Management Plan for the County of Los Angeles -- the County Plan (presently in preparation) that pulls together all the Source Reduction and Recycling Elements (SRREs) developed by the County and the incorporated municipalities is intended by California's AB 939 law to be a very specific, implementable Integrated Plan. The components needed for such an implementable plan that are not available in this document are:

- Verifiable quantification and characterization of waste actually generated in Los Angeles County (including materials presently diverted, both reported and estimates of unreported): As discussed in later chapters of this document, the County's projections of waste generation are inconsistent, and based on dubious assumptions.
- Determination of leadership and the roles of the public and private sectors: The County's present posture is that it has limited influence over future development of solid waste management. However, the County is responsible under AB 939 for developing the overall County Plan, and this requires commitment and leadership.
- Reorganization of the County's management structure to accommodate reduction and recycling as an integral part of the County's activities: This is not solely a responsibility of the incorporated municipalities and the private sector.
- The essential public input to the development of a Plan: While this document is an exhaustive review of current trends and techniques, it has not been through the extensive public review, public hearing, and comment process that is necessary for a community to claim a Plan as its own.
- Develop detailed costs for implementation: The changes in policy recommended will change the costs of solid waste management in the County. The cost increases and savings will need to be determined by the County and the Cities.

Instead, this document is meant to inspire a profound change in the County's *status quo* approach to solid waste management exemplified by the County's support for the proposed Elsmere Landfill. The County's historic policy emphasizing landfill capacity must adapt to present reality, which places pollution prevention and diversion first. In the following chapters, this document lays out the complex parameters defining solid waste management from now

through the turn of the Century, reviews alternative technologies and management structures, and recommends actions for implementation by the County and the 88 cities.

This report incorporates the dramatic changes experienced in the field of waste reduction/recycling in recent years. Since the SRREs were prepared in the early 1990s, technologies have improved, new markets have developed, existing markets have expanded, and the overall economics of waste diversion are increasingly positive. The County believes that addition of huge new landfill capacity in the County promises to maintain competition for disposal, and thus will keep disposal costs down. However, cheap disposal is only one factor to consider in developing an integrated solid waste management program, including source reduction, recycling, collection, transfer, and composting. Landfills have hidden potential costs if cleanup actions are necessary. On the other hand, diversion has no such future costs and provides the current benefits of local jobs and raw materials for new or existing industries.

Finally, this document is not a pie-in-the-sky fantasy of an ideal world. GBB is well aware of the limitations of current practices. Some waste will remain that must be managed by traditional disposal methods (i.e., landfilling). However, that is not a reason to rely on landfills as the primary approach to solid waste management. The alternative technologies and management structures outlined here are all practical, tested approaches presently in use by local governments across the nation, and real-life examples and a Case Study provided. Not one of the recommended approaches is new or revolutionary nor does any single component represent a "magic bullet" for solid waste management. Together, however, these recommendations represent a dramatic shift in vision, offering the County of Los Angeles, the 88 cities, and their inhabitants the opportunity to chart the future of integrated solid waste management and environmental preservation.

II. HISTORY OF SOLID WASTE PLANNING IN LOS ANGELES COUNTY

Los Angeles County is the most populous local jurisdiction in the United States. The population in 1995 was 9.3 million people of diverse cultural, social and economic backgrounds. This population has been growing rapidly in the last decade, with the growth rate doubling from the previous decade's annual growth rate of half of one percent to the current decade's growth rate of over one percent per year. The County covers an area of approximately 4,100 square miles and is comprised of 88 cities and a large unincorporated area. Economic activity is as diverse as the population and includes manufacturing (aerospace, electronics and automobiles), entertainment, oil and food processing industries. The Port of Los Angeles is one of the busiest ports in the country and serves as the major connection between the U. S. and Japan and the other Pacific Rim countries.

The size and diversity of Los Angeles make solid waste management planning a large and complex undertaking. Each of the 88 cities and the County play a role in the collection of the solid waste generated in the County. These roles range from permitting of private collectors to operating large collection operations. In addition, there are in excess of 250 private firms that collect solid waste in the County.

After World War II, solid waste management was mainly an individual and community problem. Many residents burned their waste in their backyards. The waste that was not burned was taken to community or private dumps, some of which practiced open burning as well. Beginning in the early 1950's, the Sanitation Districts of Los Angeles County (Sanitation Districts) initiated planning for solid waste. In the late 50's, the Sanitation Districts working jointly with the County, sited and developed five landfills and a transfer station to improve the quality of solid waste disposal and end open burning. These facilities were implemented under a series of joint powers agreements and funded by the County and the individual Sanitation Districts. Planning and policy formulation was done jointly. In the mid-1960's, the County and the Sanitation Districts established a joint trust fund and adopted the policy of setting rates at the landfill operations with the intent of both paying for operations and developing a surplus with which to expand existing facilities and acquire new facilities. In 1970, the various Sanitation

Districts pooled their resources and established a joint transfer and disposal system, operated by County Sanitation District No. 2. The County and the Sanitation Districts believed they had planned and implemented an excellent system; it was, however, one that would quickly prove to be insufficient for the waste generated in the County. In the early 1970's, materials and energy recovery as alternatives to landfilling were considered and rejected as unproven and expensive.

In 1972, the Legislature passed the California Solid Waste Management and Resource Recovery Act. This Act created the California Solid Waste Management Board to oversee solid waste management policies and programs in California. The 1972 Act assigned primary responsibility for solid waste management plans to the local governments. County solid waste management plans were the result. The state was responsible for statewide policy, approving county plans, providing technical and financial assistance, overseeing enforcement, inventorying disposal sites, and developing a state solid waste management plan. The California Solid Waste Management Board (CSWMB) developed five principles for solid waste management under the 1972 state policy:

1) Solid waste management must be planned and conducted in an economical and environmentally sound manner;

2) Solid waste management must be consistent and in compliance with state policy, county plans, and minimum state standards;

3) Solid wastes need to be reduced to conserve energy, natural resources, and land resources;

4) Material and energy recovery from wastes is to be encouraged; and

5) Adequate litter programs are needed to ensure environmental quality and public health, safety, and well-being.

The counties were required to adopt and maintain solid waste management plans which evaluated resource recovery options, and implement recovery programs which limited the dependency on landfill disposal. The CSWMB prepared planning guidelines and procedures for preparing these plans, including procedures for revising and amending plans. The CSWMB also

developed minimum standards for solid waste management. These standards still govern disposal in the state and were enforced by both the state and local governments. The CSWMB promoted waste-to-energy facilities as an alternative to landfilling in California. The CSWMB felt that a solid waste management "crisis" was real and that Southern California would run out of landfill space by 1982.

In 1976, the Solid Waste Control Act was enacted, requiring permits for landfills and transfer stations. The Act also required cities and counties to establish a local enforcement agency to enforce the permit requirements and the other provisions and regulations called for in the Act. The Department of Health Services was designated as the enforcement agency for solid waste facilities in the County.

As mentioned, the 1972 Act required local jurisdictions to develop a solid waste management plan in cooperation with cities and private industry. Los Angeles County developed its plan and the Board of Supervisors adopted it in 1976. It was approved by the CSWMB in 1977. Since that time, the County has reviewed and updated the plan, as required, several times. The current plan, the Los Angeles County Solid Waste Management Plan (the Action Plan), is dated March 1984. This, along with Revision A (August 1985), is the official document currently governing solid waste management planning in the County. The Action Plan set out the goal of developing a solid waste management system that minimized the quantity of waste produced and disposed in the County by source reduction, recycling, waste-to-energy, and/or new technologies.

Few of the goals enunciated in the Action Plan were ever realized. The waste-to-energy goals encountered strong public opposition and only two of the planned facilities were constructed. Source reduction and recycling also lagged in their implementation. The County concluded that additional solid waste facilities were required for the projected future waste flows. As a result, the County along with the County Sanitation Districts initiated the Solid Waste Management Siting Project. This effort established criteria and guidelines for siting solid waste facilities (transfer stations, waste-to-energy facilities and landfills). In addition, a search for landfill sites was initiated. The County and the County Sanitation Districts alternative site

study group reviewed an initial list of 101 potential sites. From this list, six sites were selected -- including Blind Canyon, Brown Canyon, Elsmere Canyon, Mission/Rustic-Sullivan Canyons, Towsley Canyon, and Toyon II.

In April 1988, in order to further the goals of the siting efforts, the Solid Waste Action Plan was developed. This document -- ironically containing source reduction, recycling and composting elements -- primarily focuses on landfills. The Action Plan calls for 50 years of landfill capacity held in public ownership. To achieve this goal, the Action Plan supports the expansion of existing landfill and the development of new landfills. The six sites selected in the alternative site study have been reviewed for feasibility and four have been determined to be feasible: Blind, Elsmere, Mission/Rustic, and Towsley Canyons.

In 1989, the California Integrated Waste Management Act was passed by the Legislature and signed into law. This Act (AB 939) revised the framework for solid waste management planning in the state. Most significantly, AB 939 established a hierarchy for the management of solid waste. It requires local jurisdictions to divert solid waste from landfills through source reduction, recycling, and composting. AB 939 also establishes clear mandates for diversion: 25 percent in 1995 and 50 percent in 2000. In addition to requiring cities and counties to prepare specific planning documents that demonstrate how the diversion mandates will be met, the Act revised the state level review and planning processes and established the California Integrated Waste Management Board (CIWMB).

In summary, the County of Los Angeles solid waste management planning, in the opinion of this report, is focused primarily on in-County landfill. The County's policies reflect this orientation of the Action Plan, which, until superseded, still has the force of law.

III. RATIONALE FOR A NEW APPROACH TO COUNTY SOLID WASTE MANAGEMENT PLANNING

This Chapter summarizes the complex history of solid waste management in the U.S. as it has evolved over the last twenty-five years and its relevance to practices. Striking changes in our attitudes toward, and handling of, municipal solid waste have occurred during this period. In this context, it is necessary for Los Angeles County and all of its 88 cities to catch up with the times. The public demand for change is clear, resulting in new laws, new technologies, and new economics of solid waste management. It is entirely reasonable to assume that this pace of change will continue in the next twenty-five years.

A. PUBLIC DEMAND

The development of recycling and improvements in disposal technology in the United States is largely the result of grassroots efforts. Beginning with Earth Day in 1970, the general public has become more and more aware of their environment. This awareness has been heightened by environmental and conservation organizations' efforts at public education. The battle cry of these efforts has been, "We are a throw-away society -- the most wasteful nation on earth." Out of this point of view came the question, "What can one individual citizen do to make a difference in such a complex society?" The answer came clear, "I can recycle, I can control my own trash and I can conserve resources."

This attitude fostered volunteer recycling drop-off centers, such as the one in Berkeley, California that started in the early 1970s. With the growth of such centers, volunteers realized the need for wider participation and statewide coordinated efforts. This realization produced demand for legislated local and state recycling goals, with the result that most states now have enacted recycling laws. This trend continues. A survey conducted for Waste Management Inc. in 1995[7] indicates that 63 percent of consumers favor stricter recycling laws and 85 percent feel recycling is here to stay.

[7]"Attitudes and Behavior Regarding Recycling," The Gallup Organization for Waste Management, Inc., March 1995.

B. POLICY SHIFTS

The first statewide recycling law was passed in Oregon in 1983. Today, a total of 41 states have passed recycling legislation. Initially, most of these state laws set a statewide goal to be achieved by the local jurisdictions responsible for solid waste management. These goals stated a percentage of the solid waste to be recycled or diverted by a specified year. Originally, legislation left determination of the methods to attain goals up to the local jurisdiction. However, policies have shifted toward a mandatory requirement in about half the states, and many individual communities in states with voluntary goals are also choosing mandatory practices.

The federal government, after largely ignoring solid waste for a decade, shifted to a recycling-oriented policy reflected in their integrated waste management hierarchy: source reduce, recycle (including composting), combustion (with energy recovery) and landfilling. This integrated approach was first enunciated in *The Solid Waste Dilemma: An Agenda For Action* published by the U.S. Environmental Protection Agency (U.S. EPA) in 1989. This report stated a national goal of 25 percent recycling by 1992. This policy shift at the federal level was paralleled by additional shifts at the state and local levels. Many jurisdictions shifted from recycling goals to the broader requirement of reduction and diversion, instituting bans against landfilling specific materials including yard waste, tires, batteries, white goods (i.e., large appliances), waste oil and other specific materials. Some communities passed legislation banning the sale of products made of hard-to-recycle materials (e.g., foam plastic fast food containers). However, many of these bans were rescinded as markets became available or because of court challenges by manufacturers.

As discussed in Chapter II, California passed AB 939 in 1989. This law changed the focus of solid waste management from disposal to diversion by establishing a hierarchy which places landfilling on the lowest tier and setting diversion statewide goals of 25 percent by 1995 and 50 percent by 2000.

More recently, increasing recycling goals is one policy trend that is apparent. For example, New Jersey raised the original 25 percent reduction/recycling requirement to 60 percent in 1992. The City of Los Angeles has set a 70% diversion goal and Alameda County has set a goal of 75%. Also, realization has set in that removing materials from the waste stream alone is not enough. This realization is resulting in efforts to develop or expand markets for materials, and to contribute to the development of markets through purchase of products with recycled content. Laws and ordinances are being passed designed to encourage market development, and "Buy Recycled" programs are increasing nationwide.

Policy shifts have occurred in the private sector in concert with the grassroots demand for change. New laws to protect the environment have been passed and new technologies have been developed in the environmentally aware industries. The paper industry, for example, initially adopted a goal of recycling 40 percent of the waste paper generated each year in the U.S., then raised the goal to 50 percent. Browning Ferris Industries (BFI), a leading national solid waste management company, committed its resources to recycling. As a result, BFI has become the world's largest recycling firm. Thousands of businesses throughout the U.S. have invested billions of dollars in infrastructure to separate, process and utilize recycled materials.

A policy shift being implemented in Europe is the producer responsibility or the "take it all back" system. This system shifts the responsibility for recycling and disposal of products, particularly packaging, to the manufacturer or producer. This approach is being discussed in the United States and the business sector is strongly opposed. Implementation on a nationwide, not state or local basis, seems to make the most sense as is illustrated by the experience in Europe. Producer responsibility is discussed in Appendix A.

In this climate of policy shifts toward recycling from the grassroots to all levels of government, business and industry, Los Angeles County needs a policy shift to a proactive integrated waste management policy approach that places a priority on diversion.

C. DIVERSION TECHNOLOGY

As recycling and diversion policies changed, approaches to collecting recyclables evolved beyond the Berkeley-style volunteer drop-off center. The solid waste stream, originally viewed as a heterogeneous mass, is now divided into generator sectors (residential, commercial, institutional and industrial), product categories (tires, white goods, yard trimmings, batteries, etc.) and materials (ferrous metals, glass, paper, etc.). This fractionating is due to the needs of the diversion industry as well as the unique manner in which certain waste stream components (such as tires, rechargeable batteries or household hazardous wastes) must be managed in order to reduce the impacts on landfills.

The industrial segment of the economy has discovered that, in many cases, pollution prevention (i.e., not producing a waste in the first place) not only saves money on waste management but lowers the cost of product manufacture. This trend in the manufacturing sector caused a severe economic decline in the hazardous waste management industry. As the environmental regulations tightened during the 1980's due to RCRA and other requirements, the industry developed disposal facilities including hazardous waste incinerators and "secure" Subtitle C landfills. The price charged for hazardous waste disposal rose to cover the cost of these investments and their operation. The increase in disposal fees caused the generating industries to take a hard look at the "generate and dispose" policy. The result, in many generating industries, was a change in policy to pollution prevention. This policy focuses on examining industrial processes or the way products are made, then making changes in these processes to reduce the waste discharge. Many industries found that this not only reduced the cost of waste disposal allocated to a product, but improved the product quality.

The recycling industry, both public and private sectors, has found that recycling costs can be reduced if some individual waste components are never mixed in with the waste stream. This means changing the behavior of the individual waste generator in the home, office, business, and industry, so that different materials are placed in specific containers. The custodial, waste collection and waste processing functions require changing as a result. This change in behavior can be motivated by ethical, economic or cultural factors. It can occur spontaneously or by

design. The process is accelerated when there is an overall vision or policy, such as that stated by AB 939.

This source-separation eliminates some sorting and contamination clean-up steps. Chapter VII and Appendix B discuss separation technologies that have evolved. At the same time, sortation and clean-up technology has developed to the point where, for example, plastic containers can be economically sorted mechanically into individual resins. The pace of these developments is accelerating, and solid waste management planning should take this trend into account.

Implementation of technology requires investment. In the past decade, there has been a very large investment in the infrastructure necessary to implement diversion and recycling. For example, communities have made a multi-billion dollar investment in recycling collection and processing infrastructure. The paper industry has invested billions in existing plants and building new ones to accept and process recovered paper. Other industries have decided to use recycled materials to make new products and have modified processes and plants to utilize new feedstocks. In addition, communities and states have made major investments in market development. These include tax breaks, grants, and financing to businesses that utilize recovered materials, as well as siting, permit expediting, and other facilitation services. As a result, both the supply and demand portion of the markets for recovered materials looks positive, as discussed in Chapter VII. Investment and market structures are projected to improve in the future and these trends also impact solid waste management planning.

D. LANDFILL PROBLEMS

New landfills, as well as other solid waste facilities, have become difficult to site in urbanized areas. People living in or near a potential site area, and the businesses located there, have legitimate concerns based on the inherent nature of these facilities and their impacts. These include: truck traffic, noise, dust, odors, litter, and air and water pollution. Large facilities compound these characteristics, increasing their impacts in a non-linear fashion. These reasons alone are sufficient for a community to object to the siting of a large MSW landfill facility in

or adjacent to the community. While recently adopted laws and new technologies are designed to control environmental impacts, the performance of old landfills and dumps that are releasing air and water emissions without mitigation, promoting rats and other vectors, and contain hazardous wastes serve as a basis for community protests against these facilities. As landfills compete in urban and suburban areas with other land uses, these concerns will make siting landfills more difficult and expensive.

Modern landfill technology, including multi-layer liners (using plastic membranes and clay), leachate collection and treatment, methane gas collection, monitoring wells and cover requirements, is designed to address the problems presented by old dumps. However, the technologies are new and long-term performance data is not yet available. This presents problems in predicting the long-term impacts of landfills. For example, data on large-scale liner failure in a landfill containing 50 million tons of waste (e.g., Elsmere after 10 years of operation at design capacity) does not exist. Such a failure, whether due to technical or seismic problems, could result in correspondingly catastrophic groundwater contamination and other impacts. This makes estimating the cost of long-term operations and post-closure care difficult and subject to unproven assumptions.

The technical cost is not the only consideration. Once failure occurs and environmental damage results, litigation is initiated to determine liability among the owners, operators, and users. Legal costs (based on Superfund experience) are likely to exceed remediation costs. In addition, as discussed in Chapter VI, the human health risk from air emissions from landfills is greater that of waste-to-energy facilities.

E. CHANGES IN LANDFILL MANAGEMENT

New landfill management techniques have been developing over the past decades. These approaches have arisen in part to avoid some of the landfill management problems discussed above, such as application of daily cover materials to control odors, litter and vectors and to prevent landfill fires. Another driving factor in management changes is the need to conserve landfill capacity as a result of the difficulties encountered in siting new landfills or expanding

existing fills. The experience and potential for conserving or using landfill capacity most efficiently is discussed in Chapter VI and Appendix C. The pressures to innovate landfill improvements are accelerating in all the urban/suburban areas in the country, and in many rural areas as well. Implementation of appropriate landfill conservation management techniques need to be factored into landfill planning in Los Angeles County.

F. ECONOMICS

These trends impact the economics of solid waste management. These impacts are quantum changes, rather than incremental. For example, when communities first implemented curbside collection of materials for recycling, the initial result was a 10 to 15 percent diversion of the residential waste stream. The collection of recyclable materials from each household was implemented with new trucks and staff increased costs. Refuse collection costs, however, remained the same, even though the collected quantity dropped slightly. Communities were paying for two parallel collection systems. However, increasing diversion to 50 percent requires an entirely new system. This new system includes new containers, levels of service, trucks, personnel requirements, management strategies and fee structures. Chapter VII discusses many examples. The south half of City of Seattle contracts weekly automated waste collection, once per month automated recycling collection, and separate weekly yard waste collection. This Seattle system reports 55 percent recycling. The north half of Seattle contracts with a second vendor that uses a different system, recovering slightly less of the waste stream. To provide incentive for diversion, the City Solid Waste Utility charges a variable rate fees to households, operates as an enterprise fund, and uses a full cost accounting methodology to set these fees. Seattle's variable rate is based on the size of the waste disposal container requested by a household, with a total monthly cost of less than $10.00 to a household using the smallest size container. No fee is charged for recycling and yard waste collection. (See Appendix D for a description of Seattle's program and Appendix E for a discussion of enterprise funds and full cost accounting.)

Variable rate fees (either by container size as in Seattle or by weight of the disposed material) have been shown to reduce the total quantity of waste generated. Many communities

are not benefiting from the economies available from rationalizing their collection systems in keeping with the integrated waste management philosophy. These potential savings coupled with the potential revenues from recovered materials should be included in solid waste planning.

Nationwide, the trend in the cost of landfill construction and operation is upward as a result of increasingly stringent federal and State requirements. The cost of constructing new cells and landfills includes liners; leachate collection, storage, treatment and detection; and gas collection and processing and monitoring required by recent federal and State regulations contribute to this trend. Also, the cost of closure and post-closure maintenance add additional disposal cost, as the projected costs for these expenditures must be raised during the active life of the landfill. New rules have closed smaller, inefficient landfills, and encouraged the development of very large landfills that can spread higher development and operation costs over a greater tonnage of waste.

This rising cost trend appears to be in conflict with the short-term trend of lower tipping fees at various landfills in the Los Angeles region. This local downward pressure is caused by excess capacity and increased competition for smaller quantities of solid waste. The result of this will be an industry shakeout and consolidation in southern California.

G. FLOW CONTROL

The County should recognize that the reliance on in-county disposal capacity may have a serious legal flaw. On May 16, 1994, the Supreme Court of the United States examined the constitutionality of local government exercise of preference for the use of a local transfer station for solid waste. In a majority opinion by Justice Kennedy, the Court pronounced a Clarkstown, New York ordinance requiring the use of a local transfer station unconstitutional, because it discriminated against out-of-town providers of disposal services. *C & A Carbone v. Town of Clarkstown*, 114 S.Ct. 1677, 128 L.Ed.2d 399 (1994).

Similar reasoning to the County's "in-county" capacity policy led the State of New Jersey and its Department of Environmental Protection to require each garbage district in the State to

provide for disposal capacity within the district or another district through agreements. The New Jersey plan, with its preference for in-state and in-district disposal capacity planning, was struck down by the United States Court of Appeals for the Third Circuit, in *Atlantic Coast Demolition*.

The Supreme Court decision in the *Clarkstown* case and the Third Circuit's decision in the *Atlantic Coast Demolition* case indicates that, to the extent that the County solid waste management plan relies on the Action Plan with its requirement for 50 years of in-county landfill capacity and ordinances which favor in-county disposal, it is subject to successful legal challenge.

H. CONCLUSION

The developments and trends touched on above make integrated waste management planning difficult and imperative. The current fluid situation provides Los Angeles County with an opportunity to provide the leadership and coordination needed to develop an integrated waste management system for the County and its 88 cities that will serve its citizens well into the Twenty-first Century.

IV. WASTE GENERATION PROJECTIONS

A. STATEWIDE AND NATIONAL TRENDS

The increase in waste generation rates projected in the Elsmere Canyon DEIR/DEIS and the Siting Element are inconsistent with California State Board of Equalization reports and EPA forecasts. "Time-to-crisis" estimates in the DEIR/DEIS assume a waste generation increase rate of 2.5 percent per year from years 1993 to 2000. The Siting Element uses the CIWMB Adjustment Methodology to project even higher waste generation for the Los Angeles County.

In *Characterization of Municipal Solid Waste in the United States: 1994 Update*, the U.S. EPA projects that the national per capita waste generation rate will decrease from 4.4 pounds per person per day in the year 1993 to 4.3 pounds per person per day by the year 2000. A May 1995 study prepared for the CIWMB[2] calculated that the amount of solid waste disposed in California each day was 5.9 pounds per person in 1993, compared to 7.9 pounds per person as of January 1, 1990, and 7.4 pounds per person per day as of June 1985. This shows a 20.3 percent reduction in the eight years between 1985 and 1993. The report speculates that, "(t)he reduction in disposal amount is generally believed to be the result of the start-up of many new recycling programs and the reduction in generation amounts because of a prolonged recession in California."

The most important data is local. California State Board of Equalization waste disposal records, when compared with California Department of Finance population figures, reveal a descending trend in per capita waste generation rates in Los Angeles County.[3] Also, this is consistent with the efforts toward source reduction on the part of the County and the 88 cities as enunciated in the SRRE's.

[2]*Toward Ensuring Adequate Landfill Capacity*, prepared by Environmental Science Associates for the California Integrated Waste Management Board (CIWMB), May 9, 1995.

[3]References for data sources and methodology are provided on Table V-1.

Table IV-1 presents waste generation projections for Los Angeles County based on California State Board of Equalization reports and California Department of Finance census documents. For years 1990 to 1994, actual Population figures and quantities of Waste Disposed were used in Table IV-1. Using the diversion rates projected by the County in the DEIR/DEIS, the annual tonnage of Waste Generated was calculated [Waste Generated = Waste Disposed / (1 - Diversion Rate)]. This daily Waste Generated was converted to pounds by multiplying by 2,000 and converted to a daily figure by dividing by 365 and divided by the Population to derive the Per Capita Generation rate for 1990 through 1994. Waste Generated was calculated by multiplying Per Capita Generation by Population and converted to a six day per week basis.

Beyond the year 1994, California Department of Finance Population estimates and Diversion Rates anticipated by the County were used. To project Waste Generated, the first step was completing a linear regression on the Per Capita Generation data for years 1990 to 1994. All Per Capita Generation figures below the single line on Table IV-1 represent data points on the linear regression line. Based on the regression, there is obviously a downward trend in Per Capita Generation, which is expected as public participation in source reduction and recycling continues to rise. This projection is reasonable for Los Angeles County given the demographic changes discussed below and it is consistent with EPA forecasts. The Waste Generated for all years beyond 1994 are calculated by multiplying the Per Capita Generation by the Population.

In the DEIR/DEIS, the County showed waste generation rates increasing by 2.5 percent per year from 1993 to 2000, and then by 1 percent per year for all years beyond 2000. One percent was the assumed annual population growth, and per capita generation was assumed to increase by 1.5 percent per year until the year 2000. However, Table IV-1, based on records from the California State Board of Equalization and the California State Department of Finance, reveals that these assumptions do not reflect the actual trends. The annual percent change in population is slightly more than 1 percent, but per capita generation rates are declining. The reasons for the lower waste generation trend are discussed in the next section.

In the Siting Element, the County projects waste generation using the CIWMB approved standard adjustment method. The Adjustment Methodology is built up from the 1990 (base year)

Table IV-1. County of Los Angeles Projections For Waste Generation and Disposal

Year	Population[1]	Percent Change In Population	Waste Disposed (Tons)[2]	Diversion Rate (%)[3]	Waste Generated (Tons)	Materials Recycled (Tons)	Per Capita Generation (Pounds/Day)	Waste Generated (Tons/Day)
1990	8,897,500		12,197,677	18.00	14,875,216	2,677,539	9.1608	47,677

[3]Los Angeles County Department of Public Works

waste generation figures in the residential and commercial sectors, and utilizes the projected residential and commercial sector ratios of population, employment, and taxable sales to compute adjustment factors, that are in turn used to project the waste generation in the year of interest.

EPA's report and the County's solid waste planning efforts both start with a projection of waste generation. In its past planning efforts, called "time to crisis" calculations in the DEIR/DEIS and the Siting Element, the County has developed a number of waste projections. Two of these are shown in Table IV-2: the first data column is from the 1996 Siting Element and the second data column is from the 1995 DEIR/DEIS[4]. Interestingly, the County's most recent projection shows an increase in the per capita waste generation rate. Table IV-2 provides a comparison between data from the waste projection discussed above, County historical data and a calculation based on the social and economic factors discussed in Section B of this chapter.

It is the conclusion of this report that the County's projections are high and exaggerate the need for landfill disposal capacity. Figure IV-1 shows graphically how the County's change in the projection method from the DEIR/DEIS in 1995 to the Siting Element in 1996 impacted the projected landfill need. The top curve is the current Siting Element projection; the middle curve is from the DEIR/DEIS; and the bottom curve illustrates the projection developed in this chapter. In the DEIR/DEIS, the projected quantities of waste generated per day are some 4,400 tons lower than the Siting Element, with the corresponding reduction in disposal need.

B. LOS ANGELES DEMOGRAPHIC TRENDS

Since the publication of the County Action Plan in 1988, Los Angeles County has seen its robust economy take a downturn and stagger with the loss of industries, jobs and wage growth. In the County, for example,

- There were 335,000 fewer non-agricultural jobs in 1994 than in 1988;

[4]*Draft Environmental Impact Report/Draft Environmental Impact Statement, Elsmere Canyon*, U.S. Department of Agriculture and Los Angeles County, January 1995.

Table IV-2. Los Angeles County Solid Waste Generation Estimate Comparison

Year	County 1996 Estimated Total Generation[1] (Tons)	County 1995 Estimated Total Generation[2] (Tons)	Alternative Projected Total Generation[3] (Tons)
1995	15,640,000	14,679,912	15,499,258

[3]Source: GBB.

- Unemployment in 1988 was hovering around 5 percent, but has since doubled to about 10 percent in 1994; and
- Jobs in the aerospace/high technology industries have declined by 45 percent, which translates to the loss of 125,200 jobs since 1988.

While the national recession was declared over in 1991 by the Council of Economic Advisors as other regions of the United States rebounded, in 1995 Los Angeles County remains mired in the recession with hopeful signs of weak upward swing to the end of the decade.

1. Economic Restructuring

Although not unique in undergoing restructuring from a manufacturing to a service and information based economy, Los Angeles is experiencing a far more rapid, intense, and complex transformation of its urban economy (Soda, Morals, and Wolf, 1983). In addition to the loss of aerospace jobs, employment losses hit a broad range of the County's economy. For example:

- The retail sector lost nearly 62,000 jobs, construction lost 3,000 jobs, public employment lost nearly 15,000 jobs, and the services sector remained about 10,000 jobs below its prior levels (Wolf and Grigsby, 1995).
- The value of two-way trade in the Los Angels Customs District, which grew by 13 percent during the 1988-89 period, rose by only seven percent in the 1994-95 time period.
- The County received 50,200 housing unit permits in 1988, but only received 25,300 in 1994, a decline of 50 percent.

2. Changing Demographic Climate

Los Angeles County continues to grow, from 7,477,400 people in 1980 to 8,863,200 in 1990 to an estimated population of 9,194,400 in 1993. The annual rates of growth have declined from about 1.6 percent a year from 1980 to 1990, to 1.2 percent since 1990. More importantly, Los Angeles County has undergone a dramatic shift in its ethnic composition since 1988. White-Nonhispanic share will decline from 41 percent in 1990 to 33 percent in the

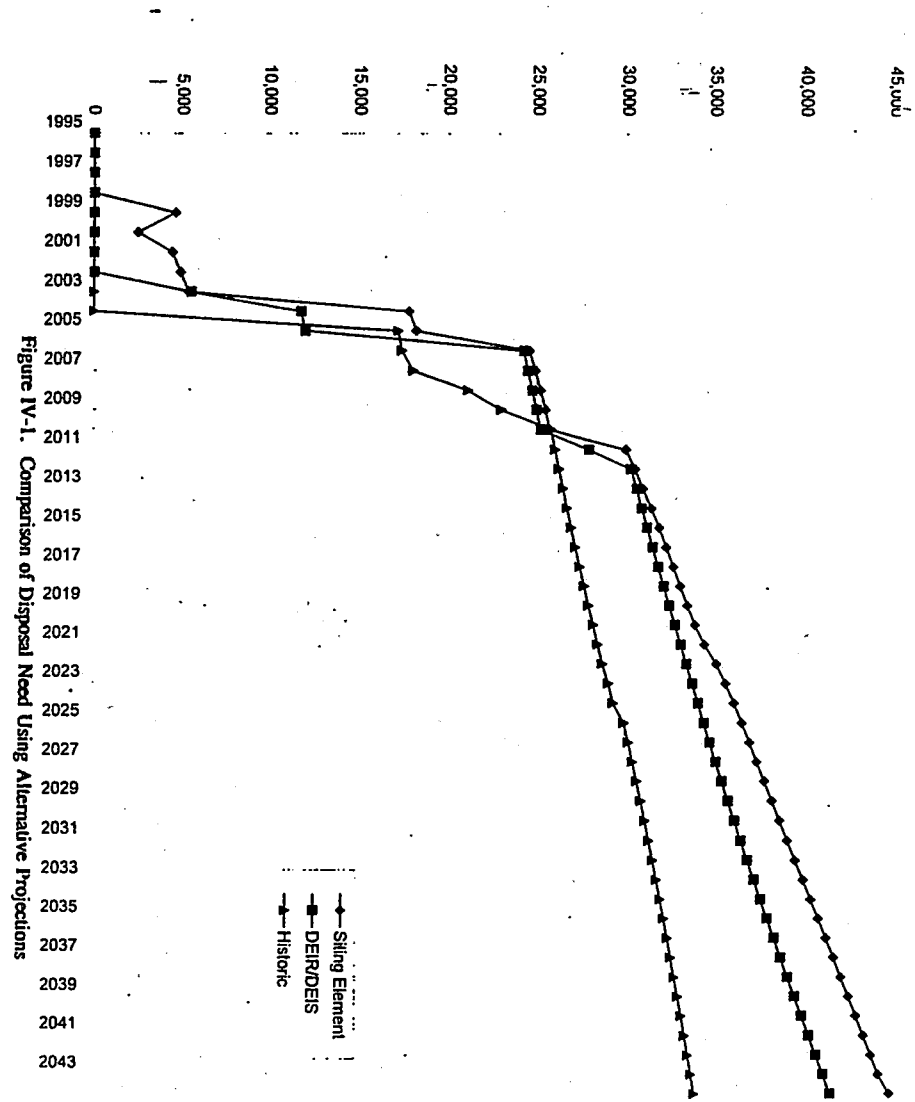

Figure IV-1. Comparison of Disposal Need Using Alternative Projections

year 2000. Moreover, the Hispanic share of the population (at 38 percent in 1990) is projected to rise to 46 percent by the year 2000. Hispanic population growth is fueled by larger family sizes and the continued influx of immigrants. White Non-hispanics are declining in share due to the outflows of population. For example:

- During the 1992-93 period, 112,800 persons moved out of Los Angeles County.
- Southern California Association of Governments has just recalibrated its projections for the five-county area downward by over half a million. They estimate that about 95,300 persons will leave the five-county SCAG region each year from 1995 to 1999. After the year 2000, the number of annual out-migrants from the SCAG region will rise to 135,000.
- The State Department of Finance estimates that almost all the growth Los Angeles County will experience over the next five years will result from immigration from abroad.

Los Angeles County has been transformed from a primarily white (Non-hispanic) population to one where Hispanic-, Asian-, and African-Americans account for 60 percent of the County's population.

3. Changing Income Structure

The vacuum created by the loss of a large number of high wage jobs associated with manufacturing and aerospace has been filled by service sector jobs paying lower wages with fewer benefits. About two-thirds of the County's Hispanic population are in non-manufacturing jobs. Hispanic-, Asian- and African-Americans are more likely to be located in the services sector, which is devoted to the generic consumption and maintenance activities required or expected in large urban areas. The kinds of retail and services provided -- markets, small to medium size retail stores, restaurants, car repair and medical care -- account for most of the low-wage job growth experienced by Los Angels County since the late 1980s.

Workers in lower occupation levels receive lower wages. With less discretionary income to spend, consumer patterns are less wasteful. Many anecdotal observations have been made

about the "conservation behaviors" of recent immigrants and lower income households who continually seek ways to extend the uses of material goods and products.

4. Implications of Waste Disposal Demand

The population forecast used in the DEIR/DEIS is too high. Any population projection estimated prior to 1990 will inflate future population growth. In 1993, the latest report available, the State Department of Finance lowered its population projections. In 1995, SCAG adjusted its 1990 population projects downward for the five-county region. The center for the Study of California's Economy has also lowered its population projections in its latest 1995 report.

The shift from a manufacturing to a service base economy will change waste disposal demand for Los Angels County. In general, service base economies are more likely to use recyclable materials, create less sludge, and produce refuse that can be converted to fuels. Many of these newer industries are more efficient and produce less waste.

The aggregate numbers hide significant compositional changes. The latest projections are lower but all assume some degree of growth. More importantly, the growth will be driven by immigration primarily from Mexico, Latin America and Asia. These changes in the components of growth and subsequent compositional changes challenge basic assumptions that waste disposal patterns of the past will be replicated in the near future.

Lower household incomes mean less waste per capita is generated. The association of higher incomes with greater consumption and waste has been well established. The current outlook of greater shares of lower income, non-white populations in Los Angeles County over the next decade projects to declining tonnage of waste disposal demand.

C. IMPORT/EXPORT OF WASTE

The Siting Element shows that 2,220 TPD of waste were imported into Los Angeles County from San Diego, Ventura, Orange and San Bernardino Counties. This totaled 692,640 tons of solid waste that were imported and disposed of in Los Angeles County landfills in 1995. The Siting Element also reports that 74,880 tons of solid waste were exported from the County in 1995. This results in a net import rate of 1,980 TPD on a six-day/week basis and 617,760 for the year. The DEIR/DEIS indicated that in 1993 the imports and exports were about equal and that the exports were approximately 485 TPD. Clearly, something has changed. The imports into the County in 1995 amounted to six percent of the waste landfilled. However, these data, in the opinion of this report, do not accurately reflect the true situation, as discussed below.

The past assumption that imports are approximately equal to exports is no longer a good assumption. The current situation is too dynamic. Several recent events exemplify the changes that affect waste import and export, including:

- The agreement between Orange County and WMI diverts the waste that was imported into Los Angeles County from San Diego County going to Riverside County instead. This agreement provides for 168,000 tons per year.
- The agreement between Orange County and Taormina Industries calls for 350 TPD in January 1996, increasing to 2,000 TPD by January 1997.
- The prospect of future importation from Ventura County has decreased due to a recent landfill expansion in Ventura.

The quantities that are included in the quarterly reporting required by CIWMB will not provide the data necessary to project future inter-county waste flows.

- The data is taken on a sampling basis for a period of one week every quarter. This is then projected over the other 11 weeks in the quarter. To be accurate, the data should be taken continually and summed for the quarterly report;

- Taking the origin data on a periodic sampling basis allows waste disposers to change their disposal location for the sampling period, thus distorting the data. This practice has been common in 1995 and it is well-known in the solid waste industry in the Los Angeles area; and
- The sampling does not reflect the fluid situation of landfills in and around Los Angeles. This is shown by the contract entered into by Orange County and others as discussed in Chapter V.

Poor information leads to poor policy and management decisions. It is recommended that the County and the 88 cities institute actual accounting of solid waste by weight and encourage the CIWMB to modify the reporting requirements for solid waste facilities so that the data reflects actual practice.

V. CURRENT AND FUTURE LANDFILL CAPACITY

The California Integrated Waste Management Act of 1989 requires Los Angeles County to continually have sufficient disposal capacity to accommodate the upcoming fifteen years of projected disposal need. The County of Los Angeles Department of Public Works has extended their planning period considerably further into the future, to 50 years as discussed in Chapter II. To demonstrate the need for the proposed Elsmere Canyon Landfill, it must be shown that the existing solid waste disposal facilities available to Los Angeles County are incapable of handling the waste generated over the 15-year period.

In the Elsmere Canyon DEIR/DEIS[11], the County predicted the "time-to-crisis" as shown in Table V-1. This is the point when there is no available landfill capacity in the County. According to the DEIR/DEIS, this occurs in 2004, when an Unsatisfied Need of 5,529 tons per day (TPD) capacity is projected.[12] The numbers and methodology used in Table V-1 and other DEIR/DEIS tables to project solid waste generation rates and disposal capacity were provided by the Los Angeles County Department of Public Works. This projection methodology covers the 50-year period preferred by the County.

Interestingly, in the Siting Element, the County provides a new and shorter "time to crisis". The County's projection from the Siting Element is shown in Table V-2 and indicates a Daily Disposal Capacity Shortfall in 1999. This loss of five years in the "time to crisis" is the result of the County's choice of data on which to base its waste generation projection as discussed in Chapter IV. In the Siting Element, the County has shortened the planning period to the 15 years required by AB 939. Summary data are presented in this Chapter, and year-by-year tables from which these summaries are prepared are included in Appendix F. The procedure used in Appendix F takes the same basic format utilized by the County "time-to-crisis

[11]Developed from Table 3.3.1, page 3-11, *Draft Environmental Impact Report/Draft Environmental Impact Statement*, Elsmere Canyon, USDA and LA County, January 1995. Format and data are the same.

[12]Actually, the table is abbreviated and does not show all of the data, including 2004. A year-by-year table is presented in Appendix F.

Table V-1. Existing Waste Management System Component Capacities and Projected Disposal Needs

2006	61,052	50.00%	30,526	1,977	28,549	24,565
2007	61,822	50.00%	30,911	1,977	28,934	24,899
2008	62,524	50.00%	31,262	1,977	29,285	25,205
2009	63,158	50.00%	31,579	1,977	29,602	25,480
2010	63,725	50.00%	31,863	1,977	29,886	25,727

ASSUMPTIONS:

1. The waste Generation Rate was estimated using the CIWMB's adjustment methodology, utilizing population and economic projections available from the State Department of Finance and the Southern California Association of Governments.
2. 25% Diversion Rate in 1995 increases to 50% by 2000 and thereafter.
3. Sunshine Canyon Landfill becomes operational on July 1, 1996.

NOTES:

1. The 1995 diposal need quantity will be updated in the final CSE once complete 1995 Disposal Quantity Reporting Data are available.
2. "tpd-6": tons per day, 6 days per week.

Source: Los Angeles County Department of Public Works, January 1996.

tables, and modifies the calculations.

The presentations in the DEIR/DEIS and the Siting Element developed by the County shows a short "time to crisis" or time to Daily Disposal Shortfall, due to its flawed assumptions and the selection of improbable scenarios. Specifically, the County fails to:

- project landfill operation at historically based waste acceptance rates (The landfills listed in Table IV-1 are all assumed to be operating at their maximum permitted capacity, so that in a given year, the projected amount of disposed waste can exceed the generated waste by up to 2.6 million tons, or over 7,000 TPD.);
- project the export of County-generated waste to out-of-County landfills;
- project the utilization of inert landfills, which have capacity for the inert fraction of the MSW stream;
- consider banning inappropriate materials, i.e., inerts and sewage sludge, from Class III landfills in Los Angeles County;
- include the capacity of the two waste-to-energy facilities operating in Los Angeles County; and
- consider the impact of the high diversion goal adopted by the City of Los Angeles.

The following section of the report adjusts the "time-to-crisis" calculations to account for the above factors. This is done in an incremental, step-by-step approach using a computer model that starts with the County's waste generation projection as published in the Siting Element and discussed in Chapter IV. The computer model starts with 1995 and projects waste generation for the next 50 years. Year-by-year tables are presented in Appendix F, which show the individual landfill and other waste allocations used to identify the exact "time-to-crisis" years and the individual effect of each step-by-step adjustment discussed in the text. Using the County's high waste projection emphasizes that alternatives to landfilling can and should be the primary thrust of the County's solid waste planning.

The majority of the information used in the adjusted tables is taken directly from documents and tables generated by the Los Angeles County Department of Public Works. The

County's calculation, as shown in the Siting Element and presented in Table V-2, projects Los Angeles County to reach a "crisis" in disposal capacity in year 1999. However, as the landfill "crisis" based assumptions in Table V-2 are modified in subsequent tables, it is revealed that the Los Angeles County solid waste disposal capacity is not in a "crisis." In fact, the "crisis" year is extended to 2014 -- fifteen years later and beyond the AB 939 planning period -- using the cumulative modifications discussed below.

A. WASTE MATERIALS FLOW MODEL

A computer model was developed to estimate the flows of solid waste materials generated in Los Angeles County. The model allocates the waste among waste-to-energy, diversion, and other alternatives to landfilling; and then allocates the remaining waste among the County landfills. Any unallocated waste is Daily Disposal Shortfall.

The computer model projects the quantity of waste needing disposal in the landfills in Los Angeles County beginning in 1996 and running through 2044. As mentioned above, the model uses the quantity of waste generated in each year projected by the County in the Siting Element. This is expressed as a daily rate based on a six-day week, as is the case in the solid waste permits. A portion of the waste generated is allocated to diversion, based upon the diversion rates projected by the County in the Siting Element. Waste is also allocated to the two waste-to-energy facilities at their capacity. Whatever waste remains each year is then variously allocated to landfills and diversion alternatives under a number of solid waste management strategy scenarios; each of the scenarios are designed to evaluate the differential impact of the various solid waste management strategies available to the County.

There a number of assumptions and parameters that are constant throughout all scenarios. These are:

1. Seventeen (17) permitted Class III landfills in Los Angeles County are included in the model. All are operating as of January 1996, except Sunshine Canyon -- which begins operating January 1997. No new landfills are opened.

2. The landfill daily allocations are initially based upon actual historic usage (1994) and rise to the permitted daily capacity as required. Total permitted capacity is the limiting factor as to how much a landfill can accept in the initial scenarios. These capacity quantities are taken from the Siting Element and are reproduced in Table V-3.

3. The waste to energy facilities are operated at 85.7 percent of maximum continuous rating (MCR). This percentage is the availability factor that allows for facility outages for preventive maintenance and repair. It is a conservative figure, as these plants can operate between 90 and 95 percent of MCR. The 1,760 TPD MCR is a seven-days-per-week figure, which is converted to the six-days-per-week figure used by the County. Therefore, 1,760 TPD on a seven day basis becomes 2,053 TPD on a six day basis. When multiplied by the availability factor of 85.7 percent, the result is 1,760 TPD on a six day basis. Also, no landfill space is allotted to the ash. This is because the Sanitation Districts are mixing the ash with cement to make concrete, then crushing the concrete, and using it for road sub-base. The County, in their calculations, uses 1,977 TPD permitted capacity for these facilities, which is higher than the plants' physical capacity.

4. The Lopez Canyon and BKK landfills are closed at the end of 1996.

5. The composition of the waste generated in Los Angeles County is that documented in the Interim Database assembled by the CIWMB and dated 1993.

The model allocates the quantity of waste generated each year based upon the historic actual uses of each landfill. For example, historically Puente Hills landfill has accepted about 16 percent of the County's annual quantity of waste needing disposal. Therefore, in projecting future disposal, the model attempts to maintain this proportion, even though Puente Hill's Permitted Daily Capacity is higher. As landfills reach their Total Permitted Capacity, or Expanded Capacity in Scenario 7, and close, the model allocates more waste to the open landfills -- until Permitted Daily Capacities are reached. Each landfill's Daily Permitted Capacity is never exceeded. Waste that cannot be allocated is summed as Unsatisfied Disposal Need. Los Angeles County overestimates the utilization of the landfills in the Siting Element. This is done by always projecting that landfills will be used at their Daily Permitted Capacity. This approach accelerates the "time to crisis" in the Siting Element by 2 years compared to that discussed in Section C, Landfill Waste Acceptance Rates.

Table V-3. Los Angeles County Landfill Capacities in Tons

Landfill	Remaining Permitted Capacity Jan. 1, 1996	Expanded Capacity	Permitted Daily Capacity	1994 Actual Utilization
Puente Hills	29,774,000	64,400,000	12,000	10,945
Spadra	2,147,000	2,147,000	3,700	2,156

Whittier-Savage Canyon	2,663,000	2,663,000	350	217

Countywide Siting Element, Los Angeles County Department of Public Works, January 1996.

The initial run of the computer model or scenario provides a baseline allocation of waste and follows the County's strategy, which is: do the minimum diversion required by AB 939 and landfill the rest of the waste. Six other solid waste management strategies or scenarios are offered. Each of these is discussed in the following paragraphs. The rational for each strategy is discussed and the impact of that strategy is provided. The "time to crisis" is identified by the year that the County has an unsatisfied landfill need. The unsatisfied landfill need is also shown graphically to allow visual comparison of the impacts. Detailed values for each scenario are provided in Appendix F. Changes in the parameters in the Scenarios are not mutually exclusive and therefore have a cumulative impact, unless otherwise specified. This reflects the fact that an integrated solid waste management system for Los Angeles County is recommended to contain a combination of programs or strategies in order to achieve its objectives.

B. LANDFILL CLOSURES

In November, 1995 BKK and Browning Ferris Industries (BFI) announced that they had concluded an agreement which would close the BKK landfill in West Covina. The agreement has several contingencies including the reopening of the Sunshine Canyon landfill. Under the agreement BFI will acquire some of the assets of BKK including the ---transfer station and the Elsmere landfill project. The closure of the BKK landfill appears to be immanent and should occur before the end of 1996. Also, the City of Los Angeles has announced that it would close the Lopez Canyon landfill as of July 1996. This closure of these two landfills have an impact on the capacity available for Los Angles County waste.

The closure of the BKK and Lopez Canyon Landfills before they reach capacity reduces the County's available landfill space by some two to three million tons and reduces the useful life of the Los Angeles disposal system. To provide the most accurate representation of the current and future solid waste system for Los Angeles County, all subsequent landfill capacity and requirement estimates will be based on the assumed closure of the BKK and Lopez Canyon Landfills in 1996.

C. LANDFILL WASTE ACCEPTANCE RATES (SCENARIO 1)

In the Elsmere Canyon DEIR/DEIS and the Siting Element, the County projects Los Angeles County landfills to be perennially operating at their maximum permitted daily capacity. Table V-3 shows that in 1994 no operating Class III landfill (except perhaps the U.S. Navy) accepted the solid waste at its permitted capacity. On average, the County landfills operated at 53 per cent of permitted capacity in 1994. However, these landfills have historically operated at less than their permitted capacity.

The result of using maximum daily permitted capacities to calculate the "time-to-crisis" is that the annual total of disposed waste exceeds the projected total generated amount. For example, Table V-1 shows that 34,842 TPD of waste required landfill disposal in 1993; however, using the Daily Permitted Capacity, 43,224 TPD are assumed to be disposed.

Therefore, 8,382 TPD of waste, or 2.6 million tons per year, is shown to be disposed of in Los Angeles County landfills that is not generated. For all years before the "crisis" in Table V-1 and Table V-2, the projected total waste disposed of exceeds the generated amount.

It is unreasonable to project landfill acceptance rates that are independent of the key parameters, such as the waste generation and the diversion rates. Assuming that all landfills operate at full daily capacity leads to projected useful lives for each facility that are consistently short. Thus, the "time-to-crisis," based on the maximum utilization of landfills at the maximum permitted disposal capacities, does not present a true picture of landfill needs.

The model calculates data similar to Table V-2, except landfills are not assumed to operate at their maximum daily capacity, and the physical capacity of each landfill is assumed to be fully utilized. The total amount of waste requiring landfill disposal, Daily Disposal Capacity Shortfall, is proportionally divided among all of the operational landfills. The portion of the total generated waste allocated to each facility is prorated based on the tonnage of waste each landfill received in 1994, as reported by the California State Board of Equalization. For example, for Puente Hills in 1995, the average 1994 daily acceptance rate (10,945 tons) is divided by the summation of the average daily acceptance rates for all of the active landfills (47,912 tons) to yield 22.8 percent. This percentage is multiplied by the tonnage of waste requiring disposal to project the quantity disposed of in Puente Hills. The 1994 average daily acceptance rate for each landfill is shown in Table V-3. The daily acceptance rates were derived by dividing the annual tonnage received in 1994 (reported by the Board of Equalization) by 312 (days/year), to reflect six days of operation per week (6 days/week x 52 weeks). After the Chiquita Canyon landfill is expanded, the permitted daily capacity will rise-to 10,000 TPD. For the purpose of the model, an average daily acceptance rate of 7,000 tons was assumed.

The first year the remaining physical capacity of a landfill is less than the permitted annual capacity, the landfill is assumed to accept enough waste to reach capacity and begin closure. For example, when the remaining capacity of Lopez Canyon is less than 4,000 TPD (the permitted acceptance rate), it is assumed that during that year, Lopez Canyon will accept enough waste to reach its total permitted capacity.

As landfills reach their total permitted capacity and begin closure, the calculations used to allocate the total amount of generated waste to the remaining operational landfills are adjusted. When landfills reach capacity, their daily acceptance rate is withdrawn from the summation of the daily acceptance rates used to prorate the allocation of waste to the various facilities, and the active landfills are responsible for a larger percentage of the annual generated waste. For example, when Lopez Canyon closes, the prorated percentage of waste allocated Puente Hills is 10,945 TPD divided by 45,561 TPD (the previous summation of the daily acceptance rates of 47,912 minus 2,351 tons, the daily acceptance rate of Lopez Canyon). However, this new percentage is not applied to the total amount of waste requiring disposal for that year because Lopez Canyon did accept some waste to reach closure. Therefore, the new percentage is applied to the total amount of waste requiring disposal minus the amount Lopez Canyon received to reach total capacity. The results of this calculation are shown in Figure V-1.

By comparing Table V-2 and Figure V-1, it is evident that projecting the landfills to operate at their maximum permitted capacity until closure has a negative effect on the "time-to-crisis. Table V-2 predicts that 1999 will be the first year Los Angeles County is without disposal capacity sufficient to accommodate the generated waste. However, Figure V-1, based on the rational assumption that the amount of waste landfilled will be approximately equivalent to the amount requiring disposal, projects 2001 to be the "crisis" year. Although there is potential for out-of-County waste to reach Los Angeles County disposal facilities, it can not be assumed that the landfills will continually operate at maximum capacity. Similarly, although there is potential for Los Angeles County waste to be hauled and disposed of outside of the County limits, it can not be assumed that the quantity of waste disposed of in Los Angeles County facilities will be less than the generated amount. From years 1995 to 2001, Table V-2 includes the disposal of over 12 million tons of waste in excess of the generated amount. This would mean that 24 percent of the waste shown to be disposed of in Los Angeles County Landfills over this period was not generated in Los Angeles County. For the year 1994, the Los Angeles County Department of Public Works reported that only 675 TPD, or 1.8 percent of the

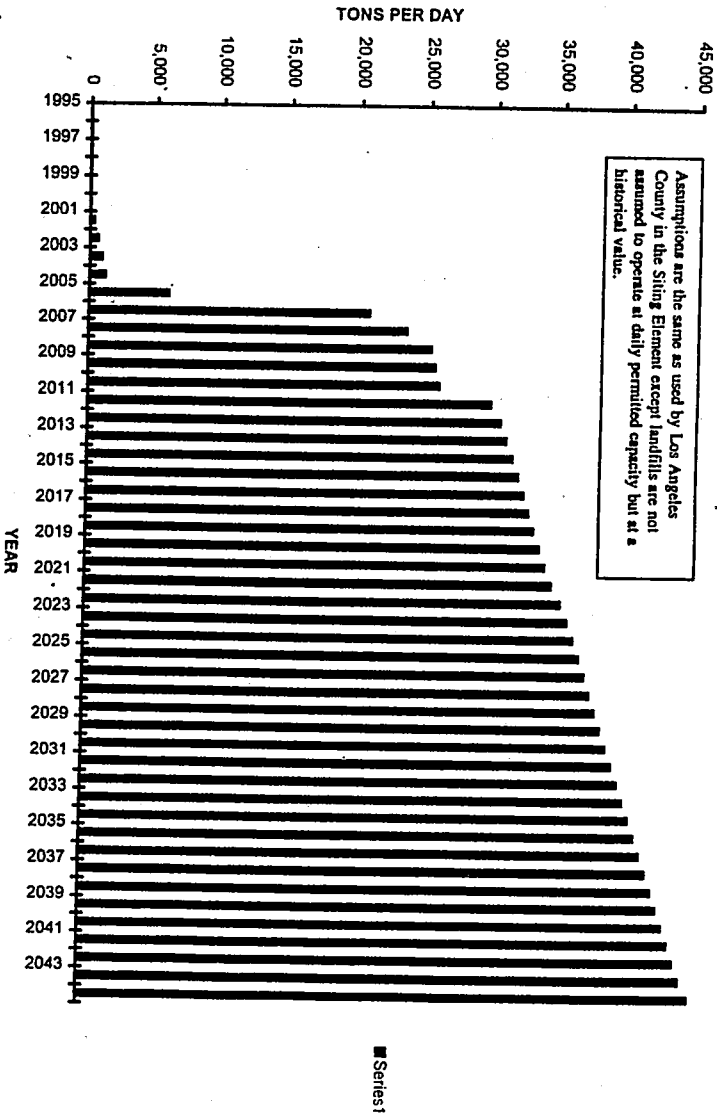

Figure V-1. Scenario 1 -- Using Historic Disposal Rates
Los Angeles County Disposal Need

disposed waste, is generated out-of-County.[13]

The first year that the County landfills experience a Daily Disposal Capacity Shortfall is 2001, when the Shortfall is projected to be 343 TPD. This is two years later than Shortfall is shown in the Siting Element. This difference is caused by the County approach of reducing the remaining capacity of each landfill by the Daily Permitted Capacity in its "time to crisis" calculation. The impact of this is mitigated slightly by the difference in the waste-to-energy facilities' capacity discussed above. The Shortfall in each year of the planning period is shown graphically in Figure V-1. As can be seen in the chart in Figure V-1, the Shortfall is small until 2006 -- when it is projected at 5,000 TPD. At the end of the AB 939 planning period, 2010, the Shortfall is 25,000 TPD.

D. OUT-OF-COUNTY ACCESSIBLE DISPOSAL FACILITIES (SCENARIO 2)

In addition to Class III landfills in Los Angeles County, landfill capacity accessible via rail or competitive truck transfer offers considerable potential in accommodating large amounts of County waste. Tables V-4 and V-5 list the out-of-County and out-of-State facilities that potentially could be utilized in a waste-by-rail system for Los Angeles County. These tables are adaptations of information developed by the City of Redlands[14] and the City of Los Angeles.[15]

Of the out-of-County facilities, Eagle Mountain, Rail Cycle/Bolo Station and Mesquite Regional Landfill projects all are planning for disposal capacities that exceed the proposed Elsmere Canyon Landfill. Western Waste, the operator of the El Sobrante Landfill, is proposing to expand the existing landfill and increase capacity from 4,000 to 10,000 TPD and a total capacity of 100 million tons. The final EIR for this is in preparation and it is expected that the

expansion permit will be granted to El Sobrante shortly. When that happens, sixty percent of the waste disposed of in El Sobrante must come from neighboring communities in Los Angeles, Orange, San Bernardino, and San Diego Counties. This expansion would allow for continued operations of the landfill from 1996 to 2026. Western Waste, the operator of El Sobrante, has submitted a proposal for 15 years of disposal services to the City of Los Angeles. Recently, Riverside County announced that it would be offering capacity at its El Sobrante landfill for $30.00 per ton. The Campo Solid Waste Management Project proposes a disposal rate of 3,000 TPD; rail haul would be required for this to be feasible.

Following its bankruptcy, Orange County began to explore the option of importing waste into the County landfills as a means of generating revenue. The Board of Supervisors approved this approach in November 1995 with the goal of importing 5,000 TPD by January 1, 1996. Contracts have been concluded with Waste Management and Taormina Industries for 2,000 TPD starting January 1, 1996. This waste is expected to be generated in Los Angeles County because Riverside, San Bernardino, and Imperial Counties all have landfills actively competing for waste.

As an example of the possible use of out-of-county facilities, effective November 1, 1995, San Bernardino County entered into a 15-year contract with Norcal Waste Systems, Inc. to provide a broad range of services relating to the administration, engineering and operation and maintenance of the County's network of landfills. San Bernardino County currently has 17 different landfills serving the 27 incorporated municipalities in the County in addition to the unincorporated area. The County receives approximately 1.3 million tons per year of solid waste for disposal.

As a result of various policy changes, the Los Angeles County landfills are in jeopardy of losing tonnage. As in other California counties, cities have the ability to contract with service providers for both collection and disposal services and sometimes do so for a combined service and do not designate where waste should be taken for disposal. Waste from several cities in Los Angeles County already have their waste disposed of outside of the county. It is possible that additional cities may follow suit.

If this situation were to occur and the County/Norcal had additional capacity that they could offer to other waste suppliers, e.g., cities in Los Angeles County or area haulers, San Bernardino County could be in a similar situation as Orange and Riverside Counties and market that capacity either directly or through their contractor. According to Gerry Newcombe, Deputy Director, San Bernardino County Solid Waste Management Department, the County's contract with Norcal allows for spot tonnage to be brought into the County system by either party.[10]

Of the out-of-State facilities, East Carbon, Roosevelt and Butterfield Station Landfills would accommodate daily disposal capacities that equal or exceed the proposed Elsmere Canyon Landfill. Franconia has a permitted capacity of 10 million tons and no daily disposal limits. The La Paz County Landfill has a capacity of 5 million tons. In addition, the CIWMB reports that both the Franconia and La Paz County landfills have the potential for expansion.

Waste from the County has been exported in the past and exportation has been expanded, beginning in January 1996. In the past, the County has assumed that the exports are approximately equal to imports. However, as mentioned above, Orange County has contracts with private waste haulers servicing Los Angeles County to provide disposal at their (i.e., Orange County) landfills for 4,000 TPD, beginning January 1, 1996. These contracts, and others that are planned, will result in significant net exports of waste from Los Angeles County. These exports, and others that could result from Orange County's decision to import waste, are not considered in the Siting Element.

Waste export depends on transfer stations to be efficient. Presently there are 19 transfer stations in Los Angeles County with a combined capacity of over 50 percent of the waste disposed in the County. These transfer stations depend on large trucks with a maximum payload of 22 tons. Table V-6 lists eleven transfer station facilities which are in the planning stages. These facilities all plan to provide access to rail transportation, some of these facilities are operating but not as solid waste rail transfer stations. Several of these are well along in the planning process and could be operational in 1997. The advantages of rail transportation are

[10]Personal conversation: G. Newcombe and H. Gershman, GBB, November 30, 1995.

lower operation costs, reduced truck traffic and lower environmental impact. A number of the projects include materials recovery processing in the planning of the rail transfer stations. One of these is the Puente Hills facility. The County Sanitation Districts have completed the final EIR[11] for a 4,000 TPD Materials Recovery Facility (MRF) located at Puente Hills with waste rail loading capability. The MRF is planned to divert 15 percent of the waste processed, resulting in 3,400 TPD requiring disposal. With rail facilities planned, it is logical that this waste would be rail hauled to one of the remote landfills discussed above.

While the Siting Element discusses rail haul, it does not take into account in computing disposal need. These exports have been, however, accounted for in this waste strategy. The exports, on a net basis, are at a rate of 2,000 TPD in 1996, and 3,500 TPD starting in 1997, which accounts for the Orange County contracts. Exports are raised to 6,000 TPD in 2001 to account for Puente Hills and other transfer station/MRF facilities on a conservative basis and continue through 2043.

The result is that the first year that Daily Disposal Shortfall occurs is 2007, extending the "time to crisis" by six years. The Shortfall in 2007 is 7,000 TPD and jumps to 16,000 TPD in 2008. This is shown on the chart in Figure V-2. At the end of the AB 939 planning period, 2010, the Shortfall is 20,000 TPD. This is 5,000 TPD less than Scenario 1, where export was not accounted for.

E. INERT MATERIALS AND BIOSOLIDS (SCENARIO 3)

Discussion of landfills in Los Angeles County usually focus on Class III sanitary landfills for non-hazardous materials. However, unclassified or inert landfills need to be included in solid waste management planning as well. Inert landfills can accept essentially non-decomposable materials, such as dirt and concrete. There are seven inert landfills in the County: Azusa, Calmat, Chandlers, NuWay, Peck Road, Reliance Pit #2, and Strathern, which were not

considered in the Elsmere Canyon DEIR/DEIS and fully addressed for planning purposes in the Siting Element. These have a total permitted capacity of over 80 million tons.

In 1990, the Board of Equalization (BOE) shows 768,422 tons of inert materials delivered to County Class III landfills, which comprises 7.4 percent of the waste stream disposed of in these facilities.[12] Much of this material is recyclable, as discussed in Appendix B. However, assuming that it must be landfilled along with the current material accepted at these landfills, the permitted inert landfill capacity will accommodate the projected amount of inert material for the next 40 years with no additional recycling.

This waste management strategy assumes that inert material is prohibited from disposal in Class III landfills in the County. Also, it assumes that inert materials are banned from Class III landfills starting in 1996 and that these landfill bans will be enforced. However, even when bans are enforced, some amount of material slips by. Thus, for this Scenario, it is assumed that the effectiveness of the ban is 70 percent.

Additionally, approximately 500 TPD of biosolids (sewage sludge) are being landfilled currently by the Sanitation Districts. While this is not a lot of material and only totals some 156,000 tons per year, there are viable alternatives to this practice as discussed in Appendix B. In Chapter IX, it is recommended that biosolids be banned from disposal in County landfills. This material is totally under the control of the County and the Sanitation Districts and, therefore, the ban should be 100 percent effective. A landfill ban on biosolids does not impact the year in which Shortfall occurs, but it does make a positive impact.

These bans result in a net reduction of six percent in landfill disposal need. The implementation of this solid waste option extends the first year that Daily Disposal Shortfall occurs by two years, to 2009, as shown in Figure V-3. This Shortfall is 4,000 TPD in 2009, at the end of the AB 939 planning period, 2010, it increases to 13,000 TPD.

[12]CIWMB-Interim Database Project - County of Los Angeles, August 4, 1993.

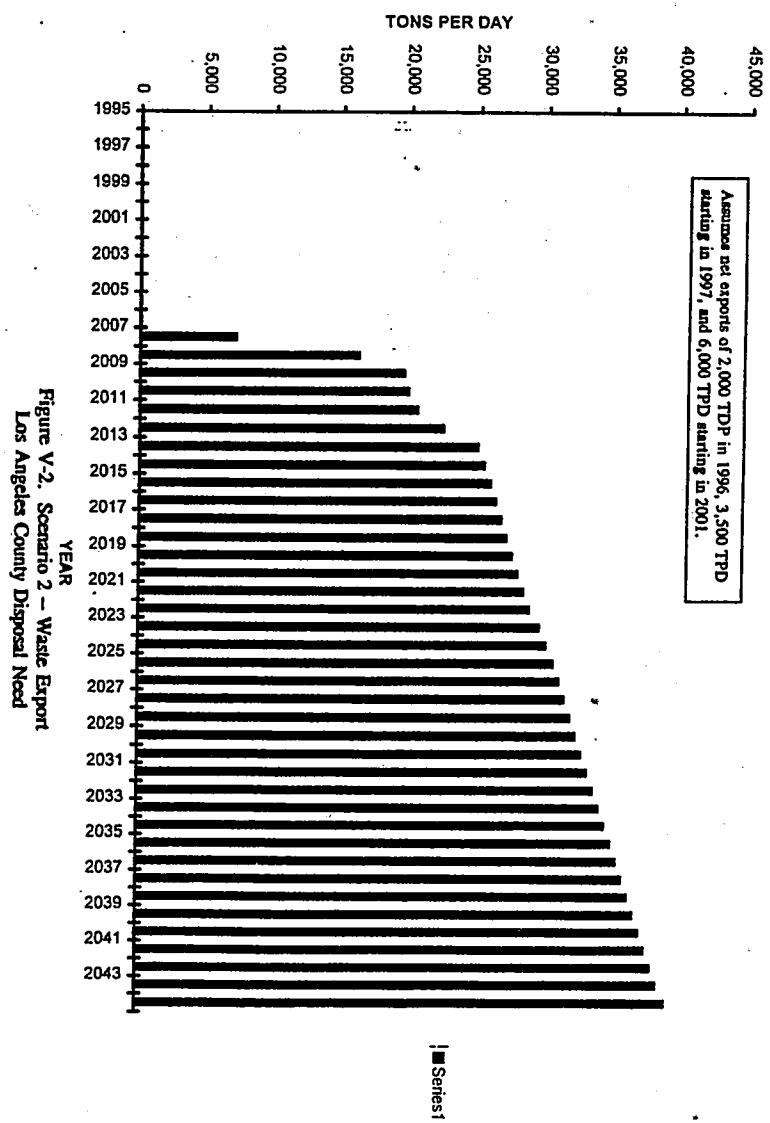

Figure V-2. Scenario 2 – Waste Export
Los Angeles County Disposal Need

F. CITY DIVERSION OF 70 PERCENT (SCENARIO 4)

The City of Los Angeles has adopted the goal of 70 percent diversion to be achieved in 2020. The planning in the Siting Element does not take the impact of achieving this goal into account in the calculation of landfill disposal need. In fact, the goal is not even acknowledged. The City generates 39 percent of the total waste generated in the County; diversion of 70 percent of this waste and diversion of 50 percent of the remaining waste generated in the County will result in an average of 59 percent diversion County-wide. Additionally, it is the position of this report that the County should be more proactive in the diversion of waste from landfills. One step the County could take is to adopt the 70 percent goal for the unincorporated areas to demonstrate the County's commitment to a diversion-based policy.

This strategy shows the results of the landfill disposal need calculation when the City and the County unincorporated area meet the 70 percent diversion goal. The waste for which the County is responsible has been included because the County has control of solid waste management policy and implementation of those policies. In Chapter 9, which outlines the recommendations for County policy, it recommended that the County adopt the 70 percent goal. Scenario 4 assumes that the City of Los Angeles and the County unincorporated areas achieve 70 percent diversion in 2020. The unincorporated area generates approximately nine percent of the total waste in the County. This added to the City's 39 percent results in 47 percent of the waste generated in the County subject to the 70 percent goal. The result is a total of 59 percent diversion in 2020.

This option does not have any impact until after the year 2000. Starting in 2001, the impact is to increase the diversion of the entire County by half a percent per year until 2020. The result is to extend the first occurrence of Daily Disposal Shortfall by one year compared to Scenario 3, to 2010. This can be seen in Figure V-4. The amount of the Shortfall is 5,700 TPD in 2010, compared to 11,700 TPD in 2011. Further reductions occur in subsequent years, as can be seen by comparing Figure V-3 and V-4.

GBB/September 13, 1996/C95035

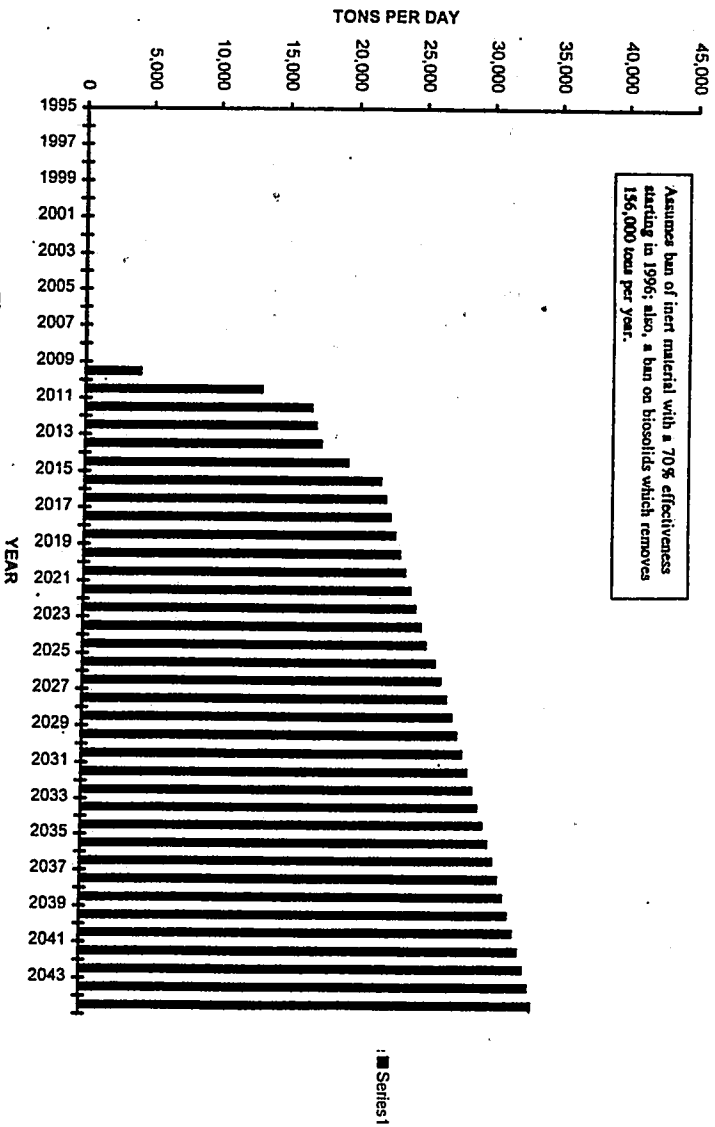

Figure V-3. Scenario 3 – Inert Material and Sewage Sludge Bans
Los Angeles County Disposal Need

V-22

The combination of the first four solid waste management strategies:

- Projecting landfill use based upon waste available and historic usage rather than permitted daily capacity;
- Export addition;
- Insert material and sewage sludge bans; and
- Diversion goal of 70 percent for the City and the unincorporated area.

result in essentially postponing the occurrence of Daily Disposal Shortfall beyond the AB 939 fifteen year planning period.

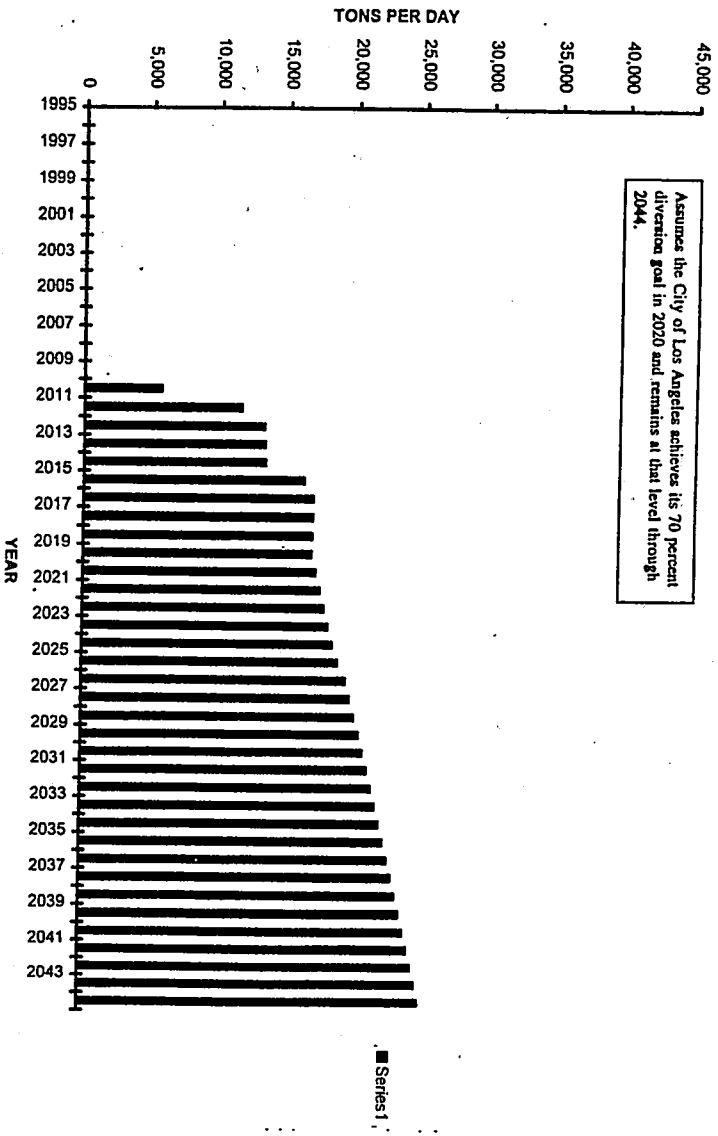

Figure V-4. Scenario 4 – Diversion Goal of 70 Percent Los Angeles County Disposal Need

VI. STRATEGIES FOR CONSERVING LANDFILL CAPACITY

Considerable experience has been gained in recent years by public and private landfill operators in utilization of technologies and management techniques for conserving landfill space. A detailed discussion of landfill conservation approaches, and examples of their applications, are provided in Appendix C. For the purposes of estimating the amount of current landfill capacity in Los Angeles County that could be saved for future use by the application of landfill conservation techniques, two have been selected: (1) chemical or foam cover and (2) biostabilization. The application of these two techniques as applied to the landfills in Los Angeles County is discussed below.

A. CHEMICAL OR FOAM COVER (SCENARIO 5)

Chemical or foam compounds have been specifically developed to be used as intermediate daily cover on landfills and are available from nationally-reputable manufacturers. Their use is widespread and performance documented at numerous operating landfills. This experience shows that foam conserves between 20 and 33 percent of landfill capacity when used in place of daily cover soil, by allowing the replacement of the dirt by solid waste.

To project a "time-to-crisis" estimate for Los Angeles County based on the use of foam cover beginning in 1997, the total remaining capacity for each landfill was multiplied by 1.22 in the year it is converted to foam. The space saved by not using dirt accounts for the 22 percent capacity increase provided by foam cover.

Figure VI-1 is the County's "time-to-crisis" table, as modified in Chapters IV and V of this document, and showing phased-in use of synthetic foam cover at County landfills. The use of foam cover begins in 1997 with all landfills in the County using foam cover in place of dirt or other materials that consume landfill capacity.

GBB/September 13, 1996/C95035

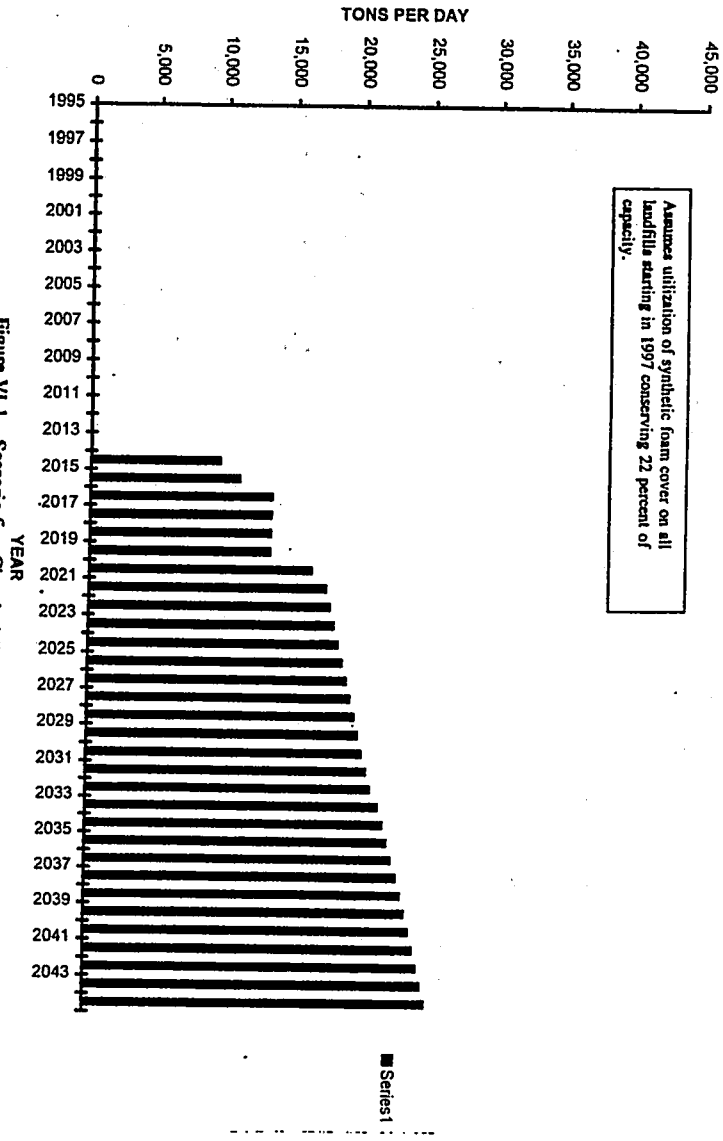

Figure VI-1. Scenario 5 – Chemical Foam Landfill Cover
Los Angeles County Disposal Need

The implementation of this technology extends the time until Daily Disposal Shortfall by four years, to 2014. In addition to moving the occurrence of Shortfall to 2014, foam cover significantly decreases the amount of the Shortfall in all subsequent years of the 50 year planning period. This can be seen on the chart in Figure VI-1.

B. BIOSTABILIZATION (SCENARIO 5A)

Current landfill management is based on a "high and dry" approach. Under this technique, both rain water and ground water are kept out of the landfill. Any water that does penetrate is collected and removed as "leachate. Leachate is treated in a waste water treatment plant and discharged. Opening and sorting old landfills has shown that very little breakdown of the organic materials takes place.[19] In many cases, old newspapers are still readable after 25 years.

Biostabilization incorporating shredding and leachate recirculation is a developing technology with excellent promise. This promotes the breakdown of the organic materials in the landfills, increases gas generation, and results in volume reduction. This allows additional waste to be deposited. Operating experience in Albany, New York indicates increases in landfill space utilization between 50 and 100 percent. At the higher levels, this could be thought of as "recycling" landfills. As mentioned previously, a discussion of operating techniques that allow additional waste to be disposed per unit of landfill volume are discussed in Appendix B.

Figure VI-2 shows the results achieved by application of this technology in the County landfills at the 50 percent level in conjunction with foam cover. Because the technology is developing and will take some time to implement, implementation is shown starting in 2000.

Figure VI-2 was developed using the same methodology as discussed in Section A except for each landfill, the amount of capacity consumed between years 2000 and 2043 is multiplied by 50 percent to estimate the capacity conserved due to biostabilization. This value is then

VII. DIVERSION OPPORTUNITIES

This Chapter focuses on the opportunities to increase diversion of solid waste from landfill disposal in Los Angeles County. The discussion provided below is a summary and evaluation of a more detailed analysis provided in Appendix B. Diversion Alternatives, supplemented by Appendix G. International Technology Applications. Appendix B looks at each of the available diversion alternatives presently in use by other communities in the U.S., assesses their appropriateness for implementation in Los Angeles County, and, where applicable, estimates the percentage of the County waste stream that could be addressed by each diversion alternative. The provision of information on alternative approaches applied in other countries in Appendix D further demonstrates that recovery of materials from the waste stream and avoidance of land disposal are not pioneering approaches to waste management, and are not unique to the U.S.

There is a correlation between a public policy that is committed to diversion and recycling and the achievement of diversion. The public policy is manifest in public documentation: statutes, regulations, planning reports and public information pieces (brochures, newsletters, press releases, instructional booklets, etc.). One familiar feature of a policy commitment to diversion is the diversion goal. Forty-one states have recycling goals and thirteen have goals of 50 percent or higher, including the state of California. The commitment is stronger and more effective when the goals are mandatory.

Many of the successful programs in the larger cities and counties have adopted and are actively working toward goals higher than state goals and on an accelerated schedule. These programs include: Seattle, WA with a goal of 60 percent and 1995 diversion of 53 percent for residential waste; King County, WA with a goal of 65 percent and a 1995 diversion of 49 percent; Ocean County, NJ with a goal of 60 percent and county-wide 1995 diversion of 59 percent where 11 of the 33 municipalities reported 50 percent or higher; and Minneapolis, MN that achieved the state goal of 50 percent in 1995.

The City of Los Angeles has adopted the goal of 70 percent recycling by the year 2020. San Jose achieved 43 percent diversion in 1995. This achievement shows what can be accomplished in only five years with a public policy decision followed up with a plan and implementation. However, in the "time to crisis" calculation the County has not accounted for the impact of the City's high diversion goal and its impact on the disposal needs.

The purpose of the exercise undertaken in Appendix B was not to identify a few selected technologies that could be calculated to bring Los Angeles County into compliance with the 50 percent diversion requirement by the year 2000. Instead, each technology or market was evaluated independently for its potential to address a specific portion of the County's waste stream. This allows comparison of what percentage could be diverted by each approach, assuming a reasonable capture rate for the type of material(s) addressed. The analysis was conducted by type of material, so as to avoid "double-counting." Diversion calculations for the materials were added to the computer model developed to calculate the landfill requirement as discussed earlier. The details of how these calculations are applied to the County Waste Stream are discussed in Appendix H.

This analysis shows that no single technical approach will meet diversion goals. However, by applying the full range of available technologies, summing together the fractions of the waste stream that could be diverted by each of the technologies deemed appropriate to Los Angeles County, the analysis shows that 74.5 percent of the waste stream could be diverted by recycling/reuse technologies by the year 2020. This is well beyond the legislatively-mandated 50 percent.

Also evaluated in this Chapter is the diversion potential of transformation (waste-to-energy) facilities. Transformation can be counted as 10 percent of the 50 percent diversion goal (i.e., a minimum of 40 percent must be diverted from disposal by other means) under California law. Review of the two existing waste-to-energy facilities and the potential of new facilities to reduce landfill capacity needs in Los Angeles County is discussed under Section VII.C below.

A. DIVERSION PROGRAMS

An analysis of current recycling programs and a diversion model to project future recycling rates was developed for this Chapter. Current program information is based on County-provided data, and diversion rates for individual materials, facilities, and programs are based on the discussion provided in Appendix B. In the discussion below, the year 1995 represents Level 1, Current Programs; year 2000 represents Level 2: Intensified Current Approaches; and year 2020 represents Level 3: Maximum Diversion.

1. Level 1: Current Programs

The current status of diversion programs can be summarized by saying that the County and the Cities have done the easy part. While not universal, residential diversion systems in the County include curbside collection, yard waste collection, and medium-level public information efforts directed to residents. Commercial and waste generators have developed, for the most part, only voluntary and economically-driven diversion programs. The County and most of the Cities have some public information programs directed toward the commercial and industrial sectors; however, these are not comprehensive efforts to maximize diversion. In summary, current programs are:

Residential
- Curbside Recycling Collection
- Yard Waste Collection
- Medium-level Public Information Campaign

Commercial/Industrial
- Voluntary Programs
- Economically-driven Programs
- Some Public Information Programs

In the DEIR/DEIS and the Siting Element, The County assumes that these programs will achieve 25 percent diversion in 1995. However, the Los Angeles County diversion analysis model, developed for this document and discussed in Appendix H, indicates a 20.33 percent

diversion rate in 1995. This rate reflects continued implementation of the above-mentioned programs. The fact that these programs have not been fully implemented, with uniform policy and administrative backup by the County and all 88 cities, is reflected in the recovery rates for the materials targeted in the programs. Recovery rates for individual recyclable materials are provided in Appendix H.

Table VII-1 shows the estimated overall diversion rate and the residential, commercial and industrial sector components from which this rate is derived on the first line of the Table (1995). Table VII-1 also shows that simply maintaining current programs will not achieve the 50 percent diversion goal required by AB 939 by 2000.

In order to attain 50 percent diversion in 2000, a new approach is required. As discussed in this document, the new approach is a County-wide policy shift to a diversion-oriented solid waste management strategy. Recommendations to the County for implementing this policy shift are presented in Chapter IX. These recommendations result in diversion programs that are executed by the public and private sectors in the County as well as by the County and the 88 cities.

2. Level 2: Intensify Current Approaches

The first step toward increasing diversion is to intensify the present approach to residential waste diversion, and increasing efforts in the commercial/industrial sectors. The commercial/industrial waste stream represents nearly half of the County waste stream. Increasing efforts in this area are essential to achieving the diversion goal. Level 2 efforts would include:

Residential
- Intensive Curbside Recycling Collection
- Yard Waste Collection
- Comprehensive Recycling Drop-off Facilities
- High-level Public Information Campaign covering source reduction, reuse, and recycling
- Mandatory Recycling Programs

Table VII-1. Projected Diversion By Sector for Intensive Programs

(TPD–6)

Commercial/Industrial
Mandatory Recycling Programs
Food Waste Composting Facilities
Comprehensive Recycling Drop-off Facilities
Public Information, Training and Assistance

In the residential waste generation sector, three new programs are recommended to meet the goal: (1) expanded curbside recyclables collection, (2) a system of comprehensive drop-off recycling centers, and (3) a more comprehensive public information program covering source reduction, reuse, and recycling. These programs are discussed in Appendix B. For the commercial and industrial waste generation sectors, four new programs are recommended: (1) mandatory recycling and diversion, (2) food waste composting, (3) a system of comprehensive recycling drop-off centers, and (4) a public information, training and assistance program targeted to these generators. This latter program should include waste audits, waste reduction, utilization of waste materials as industrial feedstocks, and recycling. The separate handling of food waste in the composting program will substantially lower the contamination of corrugated and other paper in the commercial waste stream.

The projected results of the policy shift and implementation of the Level 2 recommended programs is shown as the year 2000 line on Table VII-1. This Table indicates that implementation starts in 1996, expands through 1999, and is completed in the year 2000. The diversion analysis model projects an overall diversion rate of 48.57 percent for this scenario in 2000. While this projected rate essentially achieves the AB 939 goal of 50 percent diversion, it does not represent the full potential of a diversion-oriented solid waste management policy.

3. Level 3: Maximum Diversion

Full implementation of the diversion-oriented waste management policy requires additional programs to be developed and executed by the County and the 88 cities. Level 3 efforts include:

Residential
Intensive Curbside Recycling Collection

Yard Waste Collection
Comprehensive Recyclables Drop-off Facilities
High-level Public Information Campaign
HHW Curbside Collection
Mixed Waste Composting
Weight or Volume-Based Fees

Commercial/Industrial
Mandatory Recycling Programs
Food Waste Composting
Comprehensive Recyclables Drop-off Facilities
High-level Public Information, Training, Assistance and Enforcement
Commercial/Industrial Materials Recovery Facilities (MRFs)
Special Waste Management

Under the maximum implementation approach, three additional programs are recommended for the residential sector: (1) curbside collection of household hazardous waste (HHW), (2) mixed waste composting, and (3) variable rates. The first two programs are linked. A key problem encountered in implementing mixed waste composting facilities in the U.S. has been the quality of the end product as discussed in Appendix B. A County-wide program of HHW collection at the curb has the potential to significantly reduce toxic contaminants prior to composting, resulting in a high-quality compost product. As discussed in Appendix I, Cost Issues, variable rate programs have been shown to increase diversion rates and decrease the amount of waste generated in the residential sector. A more intensive public information program will be necessary to make these programs work. Table VII-1 shows the projected results of implementing these additional programs. These programs would be implemented incrementally, culminating in 2020. The residential sector diversion increases to 80.3 percent.

In the commercial and industrial waste generation sectors, jurisdictions would begin enforcement of the mandatory commercial/industrial recycling program requirements, and two new programs are recommended: (1) special waste management, and (2) commercial/industrial mixed waste processing. The latter program would require that all permitted solid waste transfer and disposal facilities have processing capability to divert recyclable materials from all commercial/industrial waste received. In other words, every waste management site would have a commercial/industrial materials recovery facility (MRF) equipped to recover recyclables from the mixed commercial/industrial waste stream. The special waste management program

complements the MRF program by removing from the mixed waste many of the substances that can contaminate recyclable materials. The level of public information, training and assistance would need to be increased to implement these programs. Implementation of these additional programs, with their new facilities, will take some time. Therefore, Level 3 is projected to be fully implemented in 2020. Table VII-1 shows the projected diversion rate for the commercial sector would be 44.9 percent in 2000, and at full implementation in 2020, 67.8 percent. In 2000, the diversion rate is 51.9 percent for the industrial sector, increasing to 79.6 percent in 2020.

B. MARKET TRENDS

1. Introduction

The success of any recycling program depends on the security of the markets for recyclable products. A material can be recycled only if a market and/or an end use exist. This Section presents a general overview of the various types of markets for potentially recyclable materials, the types of recyclables in the waste stream, and the uses of recyclables as commodities. In addition, this Section addresses some of the trends that have influenced markets in the past and making some projections for the future. A more detailed discussion of the markets for individual materials can be found in Appendix J.

2. Recyclables as Commodities

For recycling to work, adequate markets must exist for all of the materials. Many communities have experienced setbacks in their recycling programs due to faltering of one or more markets. In these cases, separated materials may be stored, but most ultimately are landfilled. Successful recycling is therefore dictated by markets.

Recyclable materials separated from the waste stream become commodities, similar to the virgin materials used to make nearly every manufactured item. For example, aluminum beverage cans -- either flattened, baled, or shredded -- become a metal commodity similar to

aluminum produced from bauxite (ore). The recycled aluminum cans are essentially pure aluminum and can be used to manufacture all of the products manufactured using ore-derived aluminum.

The same type of relationship described above for aluminum generally exists between virgin materials sources and recyclable materials sources for the other recyclables, such as ferrous metals, paper, glass, and plastics. However, the relationship is not identical in all cases. For example, the equipment and processing requirements for making paper from virgin material (wood pulp) are different from those used for making paper from recycled paper. Consequently, a paper mill may have the processing equipment to handle only virgin material (i.e., wood pulp) and cannot use recycled paper as feedstock. For this type of mill, recycled paper is not interchangeable with virgin wood pulp. However, as noted earlier, a large number of paper mills in the United States have made or are making an investment in the capability to use either recycled or virgin feedstock. Thus, the total market for recycled paper exhibits the characteristics of a commodity market.

Commodities markets function worldwide and suppliers are indifferent about the destination of their commodities. The objective is to achieve the highest price (net of transportation costs). A corollary objective is that the market will be a repeat customer since the supplier needs continuing markets for commodities. Dropping one customer to supply another -- whether a domestic or foreign entity -- for a higher price, will not pay off in the long run if the new customer does not offer repeat business. The first supplier will be displaced by another supplier for the market that was dropped, and the first supplier may have difficulty reacquiring the original customer.

Many factors affect commodities markets, and thus the prices paid for recyclable materials. Domestic production and production capacity, imports, consumption, energy and transportation costs, changing technology, new product opportunities, and availability of substitute material are among the factors that affect markets for recyclable materials. International markets are affected by the same forces as well as by foreign trade tariffs, currency

exchange rates, trade policy and programs, and other political forces. All of these elements are expressed in the language of economists as the law of supply and demand.

Export markets for recyclable materials are large and active for the United States. Paper is a prime example. Greatly expanded recycling programs on the East Coast have generated more paper than regional mills can absorb. At the same time, the growing economies of the Pacific Rim countries demand fiber that cannot be produced locally, forcing importation of recovered paper from the United States and Europe. Paper is now the number one export (in annual tons) for the Port of New York. U.S. exports (all grades) of wastepaper for the period in 1994 was 7.7 million tons. This represents a 31 percent increase over 1993 and two years of declining exports.

The greater number of factors involved in export markets serve to increase the volatility of prices paid for recycled materials. It is important to understand that domestic marketers of recyclable materials must compete with export markets for the same materials. Domestic markets would rather not compete with export markets nor pay the higher prices bid by foreign competitors.

The factors that can increase prices can also drive them down, although the principles of economics will limit the lower end. Suppliers will no longer be willing to sell materials below a certain price. Once the price drops below the full cost of producing virgin material, recyclable material will begin to displace the raw material (where interchangeable). Furthermore, once domestic production requirements (demand) for recyclable materials are satisfied, suppliers will look for export markets. Many overseas markets have no domestic virgin material supplies to compete for the available demand.

All of the market forces discussed above combine to affect the value of recyclable materials. Prices offered for recyclables have shifted significantly in recent times -- some increasing, some decreasing. An important point to realize in secondary material markets is that future prices will be more or less than any current price. Accordingly, recycling programs should be designed to lessen dependency on day-to-day materials prices.

C. TRANSFORMATION FACILITIES

This Section focuses on existing transformation (waste-to-energy or WTE) facilities and opportunities for optimum operation. This Section provides recommendations regarding existing WTE capacity to the County of Los Angeles, and the rationale behind the recommendations.

A discussion of additional WTE capacity is also provided because waste combustion for energy (steam and/or electricity) generation presents a very real option for diverting non-recoverable waste from landfill disposal. However, given the potential for public opposition as well as difficulty in obtaining permits for additional emissions in the Southern California airshed, new WTE facilities located in the County or the expansion of capacity at existing facilities are not considered in calculating diversion from the waste stream for the purposes of this report.

1. Current Transformation Facility Capacity

Los Angeles County presently has two operating waste-to-energy facilities. Both facilities are of the mass-burn type, where the MSW is not processed into a fuel prior to combustion. These facilities are described below:

a. City of Commerce

This facility is owned by the Commerce Refuse to Energy Authority and operated by the L.A. Sanitation Districts. The Commerce facility began operations in 1986. Its design capacity is 380 tons per day (TPD), and it generates electricity. Air emissions control equipment includes a spray dry absorber to reduce acid gas emissions, a fabric filter to capture particulates and heavy metals, nitrogen oxide (NOx) controls, and continuous emissions monitoring. In addition, lime injection into the combustion unit is used to further reduce acid gases. The Commerce facility recovers 1,600 tons per year of ferrous metals from the facility ash. The present tipping fee at the City of Commerce facility is $30.00 per ton. The overall reported recycling rate for the City of Commerce in 1994 was 23 percent.

b. City of Long Beach

The Southeast Resource Recovery Facility (SERRF) is owned by a joint powers authority (L.A. Sanitation Districts and the City of Long Beach), and is operated by Montenay Corporation. Operations began in 1988. The Long Beach facility's design capacity is 1,380 TPD and the facility generates electricity. Air emissions control equipment includes a spray dry absorber as well as a dry scrubber for acid gas control, NOx control, a fabric filter to capture particulate and heavy metals, and continuous emissions monitoring. Long Beach recovers 13,000 tons per year of ferrous metals from the facility ash. The 1995 tipping fee at the Long Beach facility is $27.50 per ton. The facility operator notes that 800 tons per week accepted from a transfer station contains a lot of dirt, lowering the heat value of the waste, and thus reducing the energy output of the facility.

Together, these two facilities have a rated capacity of 1,760 TPD on a seven-day per week basis (expressed as 1,760 TPD_7); in 1994, these facilities processed 1,686 TPD on a six-day per week basis (1,686 TPD_6).[20] Currently, the facilities report that they are operating at near capacity, but are threatened by relatively cheap landfill disposal capacity available in the region. For example, waste presently flowing to the Long Beach SERRF may be lost to the Orange County Landfill, which is offering disposal for a tipping fee at the $20.00 per ton level. Unlike landfill capacity that can be "banked" for future use, WTE capacity not used each day is lost capacity. Additionally, any low-heat value waste (such as the dirt-laden transfer station waste sent to City of Commerce), reduces the energy output of the facility and increases operating costs because of the lost revenues. Therefore, it is recommended that the County:

- develop policies and plans to fully utilize capacity at the two existing waste-to-energy facilities in the future; and
- develop policies to ensure that the waste delivered to the WTE facilities is combustible (i.e., not dirt).

[20]Based on 1994 annual tonnage data reported by the California State Board of Equalization.

2. Future Expansion and/or Additional Transformation Capacity

The DEIR/DEIS indicates that WTE alternatives were not considered because they "take material away" from diversion and recycling. This is no more true of WTE facilities than it is of landfills. Integrated waste management calls for planning a mix of alternatives. If Los Angeles County achieves 70 percent diversion in the year 2020, there will still be 10,000 tons per day of waste needing disposal. Four 2,500 TPD WTE facilities[15] would reduce the need for landfilling to approximately 3,000 TPD, taking into account the seven-day per week operation and 25 percent (by weight) ash generation of WTE facilities and would generate 280 mega watts of electrical power.

There is a total of 121 municipal waste-to-energy facilities operating in the U.S.[16] These WTE facilities are constructed using two entirely different technologies, mass burn and refuse-derived fuel (RDF). Mass burn WTE facilities accept mixed MSW into a storage area and feed this material directly into the furnaces for combustion. The heat generated is used to produce steam and electricity. Refuse derived fuel facilities have additional processing beyond receiving and storage. This processing usually includes removal of non-combustible materials and shredding the combustible portion to a uniform particle size. The shredded material, RDF, is reading to be fired directly into dedicated boilers or in combination with other fuels in existing boilers. RDF can also be compressed into pellets for easier storage and handling.

One advantage of the RDF approach is that the fuel can be prepared in a different location from the combustion site. RDF processing could be incorporated as part of the transfer station/MRF facilities contemplated for rail haul. RDF technology would allow location of combustion power plants outside the Southern California airshed, eliminating concern about the impact of WTE emissions in Los Angeles County.

[15]Ten thousand tons per day (10,000 TPD) 6 days per week converts to 8,571 on a seven day basis; sizing the facilities to be 85 percent available results in four facilities with a total rated capacity of 10,084 TPD. This was rounded to four 2,500 TPD facilities. The 2,500 TPD of ash generated 7 days per week would result in 2,917 TPD going to landfill 6 days per week.

[16]Integrated Waste Services Association (IWSA), *Municipal Waste Combustion Directory of the United States*, 1995.

A major opportunity is for existing coal-fired power plants to substitute refuse-derived fuel (RDF) for a portion of their coal feedstock. The logical choice of power plants would be those which supply some of the region's electrical power, such as the Southern California Edison Mohave plant in Nevada or the City of Los Angeles Intermountain plant in Utah.[23] Each of these plants burns approximately 12,000 TPD of coal and is accessible by rail. If they obtained 10 percent of their energy from RDF, these two plants would utilize about 5,000 TPD of RDF. This has been done by Northern States Power in Wisconsin and Minnesota, resulting in both lower air emissions and increased waste management capacity, while maintaining power output.

Expansion of the two existing WTE facilities is a possible future option for Los Angeles County; however, there are several reasons for not entertaining this option at the current time. First, the facilities must compete with relatively cheap landfill prices in the region. Expansion should have the effect of lowering their per-ton operating costs on a per-ton basis (since adding a new line or two is lower-cost than building an entire new facility), but it is unlikely that they could reach the $20/ton tip fee and without endangering the financial stability of the facilities. There is enough challenge in maintaining waste flow for current capacity. Second, expansion could mean renegotiating their power agreements with Southern California Edison, and the new power purchase rates would be much lower than present rates. Both are presently receiving $0.13 to 0.14 per kilowatt hour (kWh) with a floor price of $0.09/kWh. New rates would be about $0.01 to 0.02/kWh, which would force tipping fees up to $85 to $100/ton.

Potential environmental and human health impacts of waste-to-energy have received considerable attention from the media and from the environmental activist community in recent years. What has not been made clear in this dialogue is that WTE is a cleaner power generator that the two primary sources of electricity in the U.S., e.g., coal and oil. Further, WTE air emissions only slightly exceed natural gas (the cleanest-burning fossil fuel) in the amount of pollutants emitted per unit of energy produced. A detailed side-by-side health risk analysis that compares a new landfill with a mass burn waste-to-energy plant "...shows that WTE plants may

[23]*Electric Power Monthly*, Energy Information Administration, U.S. Department of Energy, November 1995.

be a better choice than landfills for minimizing health risks and environmental effects."[24] Finally, WTE does not present the potentially grave environmental and health impacts associated with nuclear power plants.

A recent article in *Environmental Health Perspectives*[25] prepared by scientists and health professionals from the University of North Carolina at Chapel Hill, the U.S. EPA, and Mecklenburg County Health Department, reports on the first year of a three-year study of air quality and respiratory function and symptoms in six communities. Three of the communities have waste combustion facilities (one municipal solid waste-to-energy facility, one biomedical incinerator, and one liquid industrial hazardous waste incinerator). Each of these three communities were paired with comparable communities that do not have such facilities, for a total of six study sites. The article notes that results of the first year air monitoring showed, "(d)irect measurements of air quality and estimates based on a chemical mass balance receptor model showed that incinerator emissions did not have a major or even a modest impact on routinely monitored air pollutants." Similarly, the results of the epidemiological surveys showed that, "(a) one-time baseline descriptive survey (n = 6963) did not reveal consistent community differences in the prevalence of chronic or acute respiratory symptoms between incinerator and comparison communities, nor did we see a difference in baseline lung function tests or in the average peak expiratory flow rate measured over a period of 35 days." In conclusion, the article abstract notes, "(b)ased on this analysis of the first year of our study, we conclude that we have no evidence to reject the null hypothesis of no acute or chronic respiratory effects associated with residence in any of the three incinerator communities."

Southern California receives electrical power from a variety of primary as well as alternative energy sources. Major primary sources include coal-fired out-of-State power plants

[24]"Comparing Air emissions from Landfills and WTE Plants," Kay H. Jones, *Solid Waste Technologies*, March/April 1994.

[25]Carl M. Shy, et al., "Do Waste Incinerators Induce Adverse Respiratory Effects? An Air Quality and Epidemiological Study of Six Communities," *Environmental Health Perspectives*, Journal of the National Institute of Environmental Health Sciences, V. 103, No. 7-8, pages 714-724, July-August 1995.

as discussed above. Alternative sources include hydropower (from Hoover Dam), wind energy, and some experimental solar salt ponds at the Salton Sea. As L.A. County's population continues to grow, electrical service requirements will also continue to grow. New power capacity will be developed to meet this demand. Some or all of this demand could be met by conservation measures in the near term; however, sufficient conservation is unlikely under present legislative and regulatory structures. Because of the significant line losses experienced when transmitting power long distances, development of local power generation capacity is preferable to wheeling power in from outside the Los Angeles area.

New electrical power source options include new or expanded facilities based on fossil fuels (coal, oil, and natural gas). Coal and oil, in particular, would be difficult to justify given the air pollution concerns in the Southern California Air Quality Management District (SCAQMD). Siting a nuclear power plant is also problematic due to concern about possible earthquake damage to reactor containment (e.g., Diablo Canyon).

Expansion of existing alternative energy facilities or development of new ones is also limited. There are no rivers of sufficient year-round flow volume in Southern California that can provide additional hydropower from dams, not to mention the significant environmental impacts that result from damming up rivers to fill canyons. Both windpower and solar salt pond locations are relatively remote from populated areas, so long-distance line transmission would be required if these sources are expanded. Expansion of the wind farms in the desert near the Little San Bernardino Mountains is likely to encounter opposition from the growing desert cities (Palm Springs, Rancho Mirage, Desert Hot Springs, Palm Desert, etc.), as vast areas of (potentially subdividable) desert are already dedicated to wind farms. Solar technologies, including salt ponds, are still considered developing technologies, and have cost as well as technical limitations to their application.

Another developing technology that may become available for future power generation in Los Angeles County is pyrolysis (gasification) of municipal solid waste or selected feedstocks from the waste stream (e.g., tires). This technology breaks down the organic components of the waste into combustible gases, char, and oil by exposing the feedstock to high temperatures

in the absence of oxygen. Pyrolysis has been demonstrated under various private and federally-sponsored research projects; however, no successful commercial applications exist to date. However, in the 50-year planning period considered by the County, maturation and application of this technology is a reasonable possibility.

In conclusion, waste transformation technology is a viable option for future application to two problems that need to be addressed in Los Angeles County: diversion of municipal solid waste from landfill disposal, and generation of electricity to meet new population demands.

VIII. NEW PROJECTIONS FOR DISPOSAL DEMAND

Chapters IV through VII identify flaws in the design and calculations used by the County in the DEIR/DEIS and Siting Element "time-to-crisis" projections for the Los Angeles County solid waste disposal system. Each chapter highlights a portion of these projections, and provides an alternative projection, oftentimes supported by Los Angeles County government documentation. The strategy presented in this chapter includes all of the projection alterations, except landfill expansion, made in Chapters IV through VII. The alterations include the utilization of the following:

- closing of the BKK and Lopez Canyon landfills in 1996;
- increased waste exports;
- inert landfill capacity;
- waste-to-energy facilities in Los Angeles County;
- all operational Class III landfills in Los Angeles County;
- historically justified waste disposal rates;
- foam as an alternative daily landfill cover; and
- aggressive (but obtainable) recycling diversion rates.

Two different scenarios were run with the waste materials flow model to illustrate the impact of the intensive recycling and diversion strategy that is recommended for Los Angeles County. These are:

Scenario 6A: Achievement of a 70 percent diversion goal for all 88 cities and the County in the residential, commercial, and industrial sectors. This is targeted for achievement in 2020, the same schedule as the City of Los Angeles.

Scenario 6B; A strategy of diversion through landfill bans for corrugated board (cardboard), wood and yard waste. A landfill ban on all recyclable materials would accelerate this strategy; however, bans on these three illuminate this strategy's effectiveness.

Both of these Scenarios build on the strategies recommended and illustrated in the first five Scenarios as discussed in Chapter V. However, both are mutually exclusive -- that is, they are not combined into a single model run. In actuality, an intensive diversion and recycling strategy would employ the 70 percent goal and landfill bans for recyclable materials. In addition, this strategy must include a wide variety of diversion programs and facilities for processing materials banned from landfills. These facilities range from MRF's, such as the 4,400 TPD facility planned for Puente Hills with a 15 percent diversion, to the 1,000 TPD Bio Gro/Wheelabrator facility with diversion close to 100 percent. The full program recommended for the County is outlined in Chapter VIII and technologies discussed in Appendix B.

Scenario 6A: Total County 70 Percent Diversion

This Scenario assumes that all the cities, in addition to the City of Los Angeles and the County unincorporated area as discussed in Scenario 4, achieve 70 percent diversion in 2020. This would mean the cities, which represent 53 percent of the waste generated in the County, adopt and implement this 70 percent diversion goal.

This option does not have any impact until after the year 2000. Starting in 2001, the impact is to increase the diversion of the entire County by one percent per year and to extend the Shortfall by two years compared to Scenario 5, to 2016. This can be seen in Figure VIII-1. The amount of the Shortfall is 3,500 TPD in 2016, and increases to 10,000 in 2023. Further reductions, in excess of 5,000 tons per day (TPD), occur in subsequent years, as can be seen by comparing Figure VIII-1 and VIII-2.

Scenario 6B: Recyclable Material Bans

Most recycling and diversion programs target specific materials in the waste stream. The programs in Los Angeles County are no exception. Table VIII-1 lists these materials, along with the fraction of the County waste stream which they constitute. These materials total 57 percent of the waste disposed. Table VIII-1 also shows the estimated quantity of each of these materials disposed in landfills in 1995. It is recognized that the composition of the waste stream has

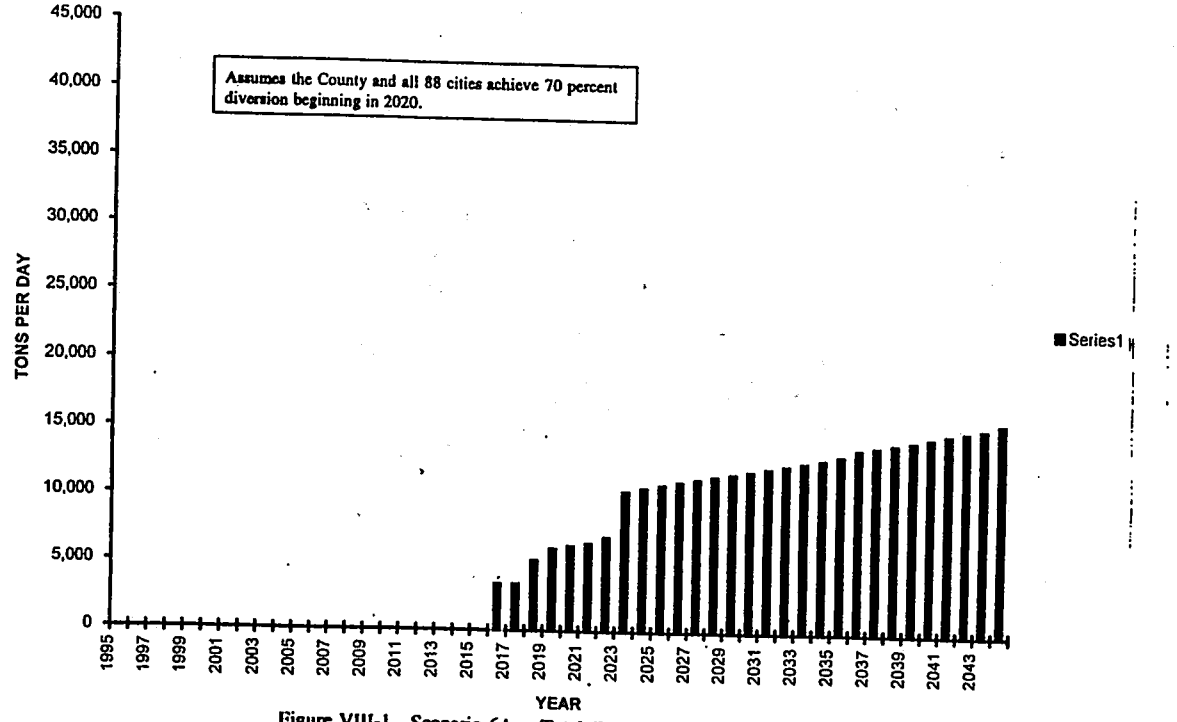

Figure VIII-1. Scenario 6A -- Total County 70 Percent Diversion
Los Angeles County Disposal Need

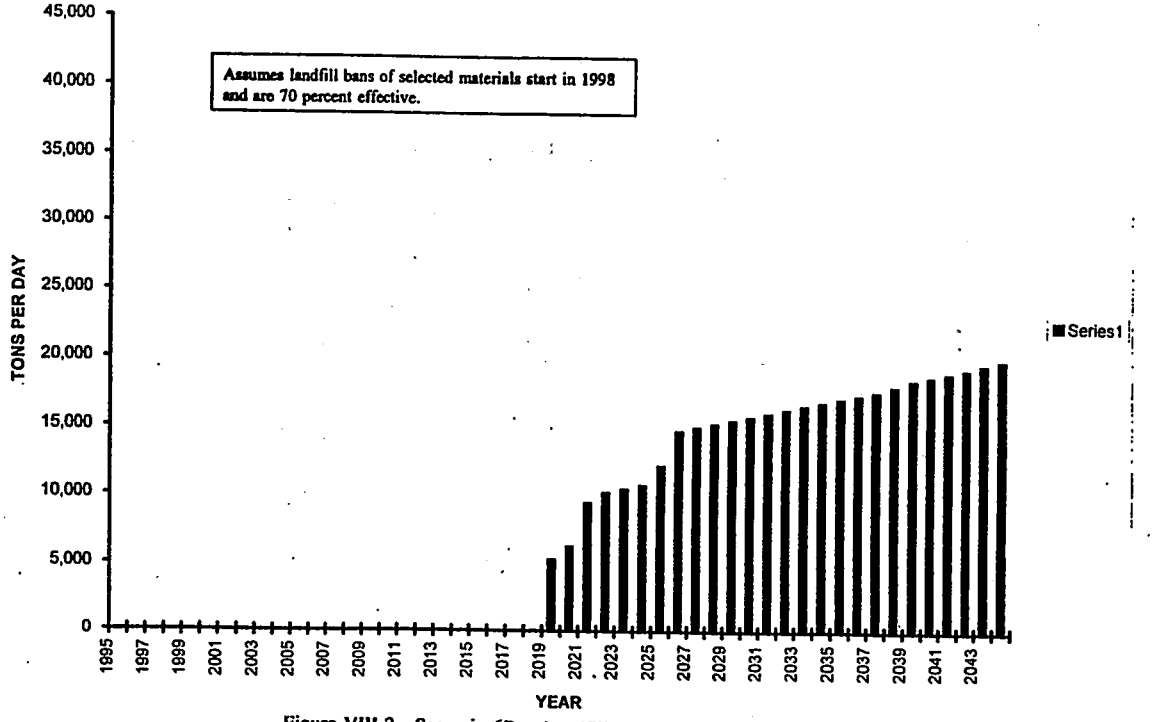

Figure VIII-2. Scenario 6B -- Landfill Bans of Selected Recyclables
Los Angeles County Disposal Need

changed since the 1990 SRRE's and the CIWMB Interim Database, the source of this data. These changes in subsequent waste composition are caused by changes in products in the marketplace. For example, the weight of individual glass and metal containers has decreased

Table VIII-1. Los Angeles County
Estimated Average Waste Composition of Selected Recyclable Materials

Waste Categories & Types	Composition As Disposed (%)	1995 Quantities Disposed (Tons)
Cardboard & Bags	8.3	868,241
Mixed Paper	11.7	1,223,906
Newspaper	5.1	533,498
Hi-Grade Ledger Paper	2.0	209,215
HDPE Containers	1.0	104,607
PET Containers	0.3	31,382
Recyclable Glass	3.0	313,822
Aluminum Cans	0.3	31,382
Ferrous & Tin Cans	3.9	407,969
White Goods	0.3	31,382
Yard Waste	12.7	1,328,513
Wood	8.8	920,545
TOTAL:	57.4	6,009,462

Source: CIWMB Interim Database Project, revised August 4, 1993.

in the last six years, and material substitutions in products, such as plastics for metals and glass, have changed the relative concentrations of these materials. In addition, the waste stream composition is altered by diversion. For example, diversion of all newspaper would result in an increase of the percentages of all other materials. Because of these changes -- and the fact that landfill bans, even when enforced, are never 100 percent effective -- not all of these banned materials will be diverted. To account for these factors, it is assumed in this Scenario that 70 percent of these materials will be diverted due to the landfill bans.

For this Scenario, the three materials (corrugated, wood and yard waste) shown in Table VIII-1 are banned from landfill disposal, beginning in 1998. These constitute 8.8, 8.3 and 12.7 percent, respectively, of the waste disposed (or approximately 30 percent total). The ban is

assumed to be 70 percent effective, allowing 30 percent of the banned material still to be landfilled. This strategy illustrates the effectiveness of immediate action on the part of the County. It postpones the Daily Disposal Shortfall until 2019, a gain of five years over Scenario 5 (Chapter VI). This is shown graphically in Figure VIII-2. Every year of delay in the implementation of this and other diversion strategies results in loss of landfill capacity. This capacity is difficult to replace.

As the model Scenarios illustrate, intensive recycling and diversion is an effective strategy for managing waste and conserving landfill space. Applying landfill bans to all the recyclable materials referred to in Table VIII-1 and developing recycling programs for these materials in the residential, commercial, and industrial sectors will further reduce the need for landfills in the County. The sooner this strategy is implemented, the greater its impact will be.

IX. LANDFILL EXPANSION POTENTIALS (SCENARIO 7)

The solid waste management strategies discussed in the previous chapters clearly will eliminate the need for additional in-county landfills in the short term (AB 939, 15 year planning period), if implemented. In the long term, The County and the 88 Cities will need to implement additional solid waste management strategies. After implementing all the strategies discussed the County and the Cities will have some 15,000 to 20,000 tons per day of waste to manage. A number of alternatives have been discussed but not included in the projections, including additional export (rail haul and remote landfilling), refuse derived fuel burned in existing coal fired powerplants, and composting. Expansion of existing in-county landfills is examined but not recommended in the following paragraphs.

Potential landfill expansions and closures play a large role in identifying the "time-to-crisis" for Los Angeles County. Depending on what is assumed with regard to expansions and closures, projections will indicate no crisis or a crisis in the next year. Projections in Table V-1, which were used in the Elsmere Canyon DEIR/DEIS, neglect the expansion potential of the landfills, which is an important factor in identifying a more realistic "time-to-crisis." In the Siting Element, six existing landfills were projected to expand and four new ones developed. It is true that there is no guarantee that permits will be renewed and extensions may be contested; however, the vast majority of landfill permits are extended, making this scenario the most probable outcome. Table IX-1 provides current and potential capacities for the landfills in Los Angeles County. All of the information in Table IX-1 is taken from reports generated by the Los Angeles County Department of Public Works.

In the Siting Element, the County suggests a scenario in which six landfills are expanded to their physical capacity. These are: Antelope Valley[20], Chiquita, Lancaster, Lopez, Puente Hills and Sunshine. In addition, the County shows the opening of four new landfills: Blind, Elsmere, Mystic/Rustic-Sullivan, and Towsley. This scenario results in a surplus of landfill capacity in the County through the planning period. The surplus is over 50,000 TPD at the end

[20]Antelope Valley has been issued a revised permit that increases daily disposal capacity to 1,400 TPD.

Table IX-1. Current and Potential Disposal Capacities for the Los Angeles County Landfills

Landfill	Permitted Disposal Capacity[1] (TPD)	Average Daily Disposal 1994	Total Permitted Capacity (million tons)[1]	Total Expanded Capacity (million tons)
Puente Hills	12,000	10,945	33.0	67.4[2,3]
Spadra	3,700	2,156	2.81	2.81
Scholl Canyon	3,400	1,587	11.5	11.5
Bradley	7,000	4,448	3.91	8.91
Sunshine Canyon	6,600	0	17.0	100.0[2]
Chiquita Canyon	5,000[4]	1,692	2.31	32.31[2]
Calabasas	3,500	2,975	12.6	12.6
Brand Park	102	18	0.6	0.6
Antelope Valley Dump	750	539	2.3	2.3
Azusa Land Reclamation	6,000	695	-- 3.5	3.5
Burbank	240	162	6.4	6.4
Lancaster	1,000	435	0.66	0.66
Pebbly Beach Disposal	33	4	0.044	0.044
Whittier-Savage Canyon	350	217	2.73	2.73

[1]Draft table, "Remaining Permitted Combined Disposal Capacity of Existing Solid Waste Disposal Facilities in Los Angles County as of January, 1995," Los Angeles County Department of Public Works, March, 1995.

[2]"Expansion of Existing In-County Waste Disposal Sites and Projected Disposal Needs," Los Angeles County Department of Public Works.

[3]Based on the calculation of 12,000 TPD x 312 days/year x 18 years (1995 to 2013) = 67.4 million tons.

[4]After expansion, the permitted daily capacity will increase to 10,000 TPD.

of the 15 year planning period, in 2010. In fact, the County's scenario of landfill expansion would result in excess landfill capacity in the County even without the new landfills.

This section (Scenario 7) examines a more modest landfill expansion strategy, where five landfills are expanded. Lopez and BKK have been dropped from the expansion list because they are scheduled to close in 1996. Also, this strategy reduces the size of the expansions of the five landfills. The values for expansion are as follows:

Antelope Valley	5.3 million tons
Chiquita	17.0 million tons
Lancaster	5.7 million tons
Puente Hills	50.0 million tons
Sunshine	60.0 million tons

These values for expansion were calculated by taking the difference between the total physical capacity and the present Total Permitted Capacity, dividing this potential increase in half, and adding this increase to the remaining Permitted Capacity. This value was then rounded.

This strategy is effective after the strategies described in Scenario 1 through Scenario 5 in Chapter V are implemented, as is the landfill conservation strategy discussed in Chapter VI. Intensive recycling and diversion described in Scenario 6 are not activated. The strategy in this Scenario postpones the "time to crises" to 2023, well beyond the AB 939 required planning period. Further, the Shortfall, when it does occur, is not severe, starting at 800 TPD and increasing to 10,000 and growing slowly thereafter. This is shown graphically in the chart in Figure IX-4.

Los Angeles County Disposal Need

X. RECOMMENDED COUNTY ACTIONS

This Chapter draws upon preceding Chapters to establish the County's potential for a leadership role, as well as pointing out direct actions presently within the purview of the County government. Recommendations cover:

- Changes to the County structure that will foster a policy shift to diversion/transformation as the preferred methods for addressing solid waste, and
- Specific, practical applications.

Sections within the Chapter, where appropriate, estimate the amount of diversion that can be accomplished by implementing a particular recommendation.

The estimated cost of implementing a recommended plan is normally developed as part of the planning process. Because this report has been developed without County input, however, there are many unknown cost factors that make estimation of overall costs a misleading exercise. Some critical cost issues are discussed in Appendices E and I. It should also be noted that cost is not the deciding factor in determining the level of implementation for solid waste diversion programs; State law and federal EPA guidelines make it clear that source reduction/recycling are the preferred modes of managing solid waste, whether it is cheaper in the short run or not. Further, the guidelines for Environmental Impact Statements require consideration of alternatives without regard to cost.

A. USE OF COUNTY SOLID WASTE TASK FORCE

The Los Angeles County Solid Waste Management Committee (the Committee) has been in the forefront of solid waste planning for years. With the passage of AB 939, the Committee was given the task force responsibility as required under this legislation, by the County. The Committee has provided policy guidance for the Los Angeles County Board of Supervisors. Also, the Committee is responsible for coordination of solid waste management issues on a county-wide basis. The Committee has failed to develop a policy direction for the County that focuses on alternatives to in-county landfills.

Recommended County Action

The Board of Supervisors should reconstitute the Committee and give the reconstituted Committee the charge of developing diversion-oriented policies for the County.

B. WASTE DISPOSAL PRACTICES OF COUNTY DEPARTMENTS

Waste from government-owned and/or operated facilities can be a substantial portion of the municipal waste stream. This waste often goes unnoticed because it is considered "commercial waste" in traditional waste composition studies. However, where localities have conducted an analysis of that portion of the commercial waste stream attributable to government operations, the results can demonstrate significant opportunities for government diversion activity. For example, in the City of Los Angeles, an estimated 2.3 million tons of the total waste generated in 1995 was under City control and 29 percent of this was generated by government agencies.

Los Angeles County Public Works Department should seek assistance from other County Departments in achieving AB 939 goals and extending the life of in-County landfills. This is particularly important in light of the increased emphasis being placed in the County on commercial and institutional recycling rates and the expansion of residential curbside programs to include mixed paper and yard trimmings. All County agencies should be responsible for achieving 50% or greater recycling rates as well, including county offices, health facilities, prisons, parks and recreation facilities, maintenance facilities, etc.

Clearly, County Public Works does not have the authority to require such diversion activity from other County agencies. However, it can, and should, use its position to gather and analyze data, track recycling rates, and make recommendations to the County Board of Supervisors, which can then direct each individual agency to institute and report on diversion activities.

The ancillary benefits of such an approach are also substantial. Agencies are often unaware of their solid waste costs, focusing on diversion will result in significant source reduction as well as recycling. These efforts will produce cost savings to the generating agencies.

The County should recommend that the Board of Supervisors require the following of each County agency:

1. Commit to 50% recycling rate by 1998 and 65 percent by 2000.
2. Develop a plan to achieve these diversion rates, with year to year goals.
3. Prepare a report in 1996 that contains the following information:
   a. Describe how solid waste for the agency is picked up and disposed (agency employees, contracts with haulers, etc.)
   b. Provides a cost estimate for disposal (total and cost per ton)
   c. Describes service level utilized (number of containers, size of containers, frequency of pick-ups, etc.)
   d. Estimates the tons/year disposed of by the agency.
4. Prepare a report in 1996 that summarizes agency recycling activity, if any, and quantifies the cost, cost/benefit of those programs.
5. Submits quarterly narrative reports to the Department of Public Works, which are then summarized and included in DPW's Quarterly Report on the Action Plan to the Board of Supervisors.
6. Submits annual reports to the Board of Supervisors on status of recycling programs, including quantification of diversion rate.

The County Sanitation Districts of Los Angeles County (Sanitation Districts) operate two buy back/drop off centers for the general public: one at the Puente Hills Landfill and the other at the Palos Verdes Landfill in Rolling Hills Estates. The Palos Verdes Recycling Center opened in November 1977 and the Puente Hills Recycling Center opened in October 1982. Customers can receive money for their recyclables or "donate" them to a designated charity.

These are in addition to the four active landfills, a transfer station, three landfill gas-energy facilities, and the Commerce waste-to-energy plant operated by the Sanitation Districts.

Since their opening, both facilities have added materials to the list of recyclables accepted from the public and currently both accept glass in three colors, aluminum, steel, PET and "other plastic" containers, and newspaper. Over time, each facility gradually increased tonnage and customers and then began to experience a decrease in both tonnage and customers. For example, the Puente Hills Recycling Center started in 1982 with 424 customers bringing in 36 tons, grew to 7,499 customers bringing in 376 tons in 1991, and then dropped to 180 tons received from 4,535 customers in 1994. Similarly, the Palos Verdes facility accepted 449 tons from 4,627 customers in 1997, grew to 4,597 tons from 23,914 customers in 1991, and dropped to 689 tons from 16,688 customers in 1994. While some of this drop in the quantity of materials can be attributed to the initiation of curbside programs throughout the County, some of this drop is due to a lack of public information and promotion.

Both facilities could assist in the achievement of County-wide goals by filling gaps in curbside service and by encouraging residents and small businesses to drop off source separate materials for free as a means of avoiding disposal charges. The easily recycled materials, including corrugated cardboard, magazines, office paper and mixed paper, should certainly be added to the materials accepted by the centers. Harder-to-recycle materials, including white goods, tires, batteries, separated construction and demolition waste, and wood, should also be accepted. In addition, a drop-off site for clothing and small durables could be added in cooperation with a charitable organization. Information could be distributed at the site regarding other opportunities to divert materials in Los Angeles County. Through this and other types of activities, the Sanitation Districts could fill voids in County diversion services and increase overall tonnages diverted County-wide.

Recommended County Actions:

It is recommended the Sanitation Districts expand the drop-off system. This should include expanding the material accepted as discussed above and increasing the number of sites. The Sanitation Districts own and/or operate some 20 facilities throughout the County. An expanded citizens drop off center should be located at each of these facilities, if practical.

The Sanitation Districts should adopt and implement the 65 percent diversion goal for its facilities (offices and plant as applicable), as discussed above.

C. UNINCORPORATED AREA ACTIONS

Based on Los Angeles County's AB 939 disposal surveys, the unincorporated area of the County landfilled 211,057 tons of waste per quarter, compared to 2,923,059 tons landfilled from all localities in the County. This represents 7.22% of Los Angeles County landfilled waste, a substantial portion of County landfill usage. Overall, County quarterly disposal reports indicated that solid waste facilities in the County received a total of 289,010 tons of waste from the unincorporated area, compared with 3,756,290 tons from all Los Angeles County localities, or 7.7% of the total. The latter includes tons salvaged, transformed, landfilled and used as ADC in solid waste facilities in the County.

Los Angeles County Department of Public Works has a unique opportunity to both extend landfill life and to provide a leadership role in demonstrating diversion opportunities through its management of waste collection systems in the County unincorporated area. Therefore, it is recommended that Los Angeles County use the unincorporated area as a demonstration for intensive recycling and diversion. To do this the County would need to implement the Level 3 Maximum Diversion program described in Chapter VII.

Recommended County Actions:

Los Angeles County should implement the maximum diversion program. To initiate this program it is recommended that the County:

- Make a formal announcement to adopt the program;
- Adopt a 70 percent diversion goal for the unincorporated area;
- Establish a program team to develop a detailed plan and implement;
- Establish an enterprise fund administration and accounting system for solid waste in the unincorporated area solid waste system and fund it.

D. MANAGEMENT OF COUNTY BIOSOLIDS

The Sanitation Districts collect and treat wastewater for 78 cities and unincorporated areas in Los Angeles County. The Sanitation Districts operate 11 wastewater treatment facilities with a combined daily flow of more than 500 million gallons. Seven of the facilities are located in the metropolitan area of Los Angeles County, two in the Santa Clarita Valley, and two in the Antelope Valley.

The largest of the facilities is the Joint Water Pollution Control Plant located in the city of Carson. Approximately 1,250 wet tons of biosolids are generated at this facility daily. Total wet tons for 1994 were 473,200. Wastewater treatment for the Santa Clarita Valley is conducted at the Saugus and Valencia Water Reclamation Plants and solid generated during treatment are processed at the Valencia facility. A total of 20,000 wet tons of biosolids were disposed of in 1994 at the Chiquita Canyon Landfill. The Antelope Valley facilities include the Lancaster and Palmdale Water Reclamation Plants. Approximately 20 wet tons are produced daily from these facilities, where anaerobically digested, dried biosolids are intermittently released for soil amendment material. For example, the Antelope Valley biosolids have been used in agriculture, for landscaping at the Mira Loma Jail, and to revegetate perimeter slopes at local landfills.

Despite contracts for composting, land application, and Nox reduction in cement kilns, some 3,000 wet tons per week are sent to Puente Hills Landfill from Los Angeles County, out of a total of approximately 9,600 tons per week produced by all County-operated facilities. At an average of 500 tons per day (TPD) disposed in Puente Hills Landfill (6 day week), biosolids utilized almost 4% of Puente Hills daily capacity (13,200 TPD) and 4.6% of the average daily tonnage disposed of at Puente Hills in 1994. This was mentioned in Chapter VII and represents a significant usage of Puente Hills capacity which could be utilized to either extend Puente Hills' landfill life or to accept residential and commercial waste in the future which would otherwise have to be disposed of at out-of-County or out-of-state landfills.

Recommended County Actions:

The Sanitation Districts should institute a policy of 100% composting, land application and NO_x reduction in cement kilns for all County-generated biosolids, with Puente Hills Landfill disposal utilized only as a backup when other alternatives fail in an emergency.

Since sludge was not calculated in the AB 939 aggregated County tonnages, this means that the 500 TPD of material sent to Puente Hills shows up County-wide as an increase in disposed waste over 1990 in the disposal surveys done for AB 939 compliance in 1995. While it is not certain, the small amount shown in the CIWMB interim database was probably as a result of the City of Los Angeles disposed tonnage.

E. MANAGEMENT OF COUNTY LANDFILLS

Landfills in Los Angeles County can be managed to maximize diversion and conserve landfill capacity. The start for this approach would be the adoption of a policy by the County that recognizes that land for urban landfills is a scarce and diminishing commodity. The current landfill tipping fees do not reflect this fact; however, it is demonstrated by growing public objection to new and existing landfills. The County policies should reflect this problem, and take concrete action. The recommendations offered in this Section are some of the actions the County could take.

First, the County should implement Item 5 of the 1988 Action Plan, direct billing for collection and disposal of solid waste. To be most effective, this billing should itemize the various components of the cost: recycling, yard waste, solid waste collection, disposal, etc. The basis for this must be full cost accounting, utilizing an enterprise fund as discussed in Appendix E. The coupling of direct billing with a variable rate structure based on weight or volume has been shown to reduce total generation of waste and to increase diversion in communities that use this approach. A variable rate structure is applicable to both residential and commercial wastes. Currently, larger U.S. private haulers are implementing weight-based systems using scales on their trucks to weigh each container as it is dumped. They are finding that the cost of the system, about $10,000 per truck, is paid for by more accurate billing of generators based upon weight the same way the hauler pays by weight at the landfill. The City of Seattle Case Study provided in Appendix A describes the application of a variable rate system to a residential integrated waste system.

As discussed in Chapter V, prohibiting landfill disposal of specific materials is effective in achieving diversion. Enforcement of bans for such materials as yard waste, white goods designated recyclables, and so on cannot be 100 percent effective for a variety of reasons, as discussed in Chapter V. However, if 70 percent effective, bans would reduce the material being landfilled by approximately 21 percent.

It is recommended that a chemical foam system be adopted as the daily cover method used by all the landfills in the County. This alternative landfill management technique is discussed in Chapter VI. Included as part of this is the recommendation that shredded yard waste no longer be permissible as alternative daily cover. Implementation of this recommendation will increase the capacity of all the landfills by 25 percent (i.e., the space taken up by the use of dirt and other cover materials such as shredded yard waste).

Technology discussed in Chapter VI is under development to accelerate the breakdown and stabilization of the mainly organic material in landfills using shredding, moisture adjustment and leachate recirculation. Los Angeles County could initiate a development project to demonstrate the effectiveness and cost of the approach. This would involve implementing this

management technique in one operating landfill and collecting data on operational and cost elements. If successful, accelerated biostabilization has the potential to double the capacity of existing landfills, based upon the Albany, New York experience.

Recommended County Actions:

- Implement direct billing of a variable rate based upon full cost accounting in the unincorporated areas. It is also recommended that the County meet with the Cities to develop cooperative methods to implement similar systems in all jurisdictions in the County. It is recommended the County and the Cities pass ordinances to require similar billing by private haulers and that the data collected be part of a periodic reporting requirement.

- Prohibit the disposal of the following materials in all public and private class III landfills in the County: materials designated for recyclable collection, yard waste, white goods, tires, vehicle batteries, inert materials, wood, and biosolids.

- Encourage the adoption of foam (or tarp) daily cover in lieu of dirt or green waste alternative daily cover at all landfills in the County. The County could initiate a demonstration program at one landfill to test effectiveness of various products, and provide a site for training public and private landfill staff.

- Prohibit the use of shredded greenwaste as alternative daily cover.

- Initiate a demonstration project for accelerated biostabilization of landfilled organic wastes, documenting costs and experiences, and providing training to other landfill owners and operators.

- Require all commercial/industrial waste disposal to be MRF-processed, at transfer stations or at the landfill sites.

- Develop commercial/industrial waste Materials Processing Facilities (MRFs) at landfills located in the County, as discussed in Chapter VII. MRFs may be publicly-sponsored, private enterprises, or joint efforts.

F. MANAGEMENT OF TRANSFORMATION FACILITIES

While the County does not have direct control over the operations of two existing waste-to-energy (transformation) facilities in the County, the Sanitation Districts have direct participation in both facilities. The 380 TPD City of Commerce facility is operated by the

Sanitation Districts. In the case of the Southeast Resource Recovery Facility (SRRF) in the City of Long Beach, the Sanitation Districts entered into a Joint Powers Authority (JPA) agreement; this JPA owns the SERRF in Long Beach. In addition, the County has the power to direct waste from County-operated transfer stations and through County waste collection contracts to these two facilities.

It is recommended that the County:

- In consultation with the operators of the Commerce and Long Beach facilities, direct waste from County-operated transfer stations to the waste-to-energy facilities in amounts sufficient to maintain MCR (maximum continuous rating) at each facility;

- Manage incoming wastes at transfer stations so that largely non-combustible loads are diverted to landfill or inert landfill disposal rather than transferred to the waste-to-energy facilities;

- As feasible, require combustible waste collected by the County or by private haulers under County contracts be delivered directly or via transfer stations to the two waste-to-energy facilities; and

- Work with the two cities and the Sanitation Districts to explore potential for expanding capacity of the two facilities to meet permitted limits (3,230 TPD).

G. MANAGEMENT OF COUNTY TRANSFER STATIONS

In 1994, the County of Los Angeles reported that approximately 19 transfer stations were operating in the County.[21] Transfer stations are used by individual communities or solid waste collection firms to optimize their transportation costs. This is accomplished by limiting the use of small collection trucks to picking up wastes from the generators and transferring the waste to more efficient transfer trailers for long-distance hauling to the disposal site. Due to the fact that transfer stations are sited to reduce collection truck route distances, they are designed to serve a defined area and generally range in size from 500 to 3,000 TPD.

[21]County of Los Angeles, Department of Public Works, Waste Management Division, *Nondisposal Facility Element*, March 1994.

Many private transfer stations perform some "dump and pick" operations to recover high grade materials. These operations have little specialized equipment, using a front-end loader and laborers to separate the materials on the tipping floor. The diversion rate for this type of operation ranges from zero to ten percent of the incoming waste. More technically advanced transfer station recovery systems are called mixed waste processing facilities (MWPFs). A minority of the 19 transfer stations in the County have invested in separation equipment to actively process all or a portion of the waste stream and can be classified as MWPFs. Based upon data from facilities surveyed by GAA,[22] the recovery rate for these facilities ranges between 8 and 30 percent of the incoming waste stream. Only one of the 19 transfer stations in the County exceeds 30 percent and processes a significant waste quantity.

In contrast, the 950 TPD MWPF owned by the City of Sunnyvale and operated by Western Waste diverts 46 percent of the incoming waste. This facility operates on a mix of 25 percent residential waste and 75 percent commercial waste. Some source separation takes place prior to collection of the waste delivered to the MWPF. The Sunnyvale MWPF recovers 12 grades of paper, all six plastic resin categories and other plastics, metals, glass, tires, batteries, white goods, waste oil and household hazardous waste. To achieve diversion at this scale, a substantial investment in building and processing equipment must be made. The Sunnyvale facility cost in excess of $23 million. In addition, the waste stream coming into the facility must be managed to facilitate recovery of the separate materials. This means not only segregating waste loads on the tipping floor, but modifying collection routes to reduce contamination of recoverable materials.

Transfer station planning for the future in Los Angeles should incorporate rail transfer for waste and recyclable materials in the siting and design stages. While this will tend to make the facilities larger due to the capital investment necessary, the advantages are more than off-setting. The first advantage is the reduction in truck traffic achieved by using rail transport instead of long-haul transfer trailer trucks. Second, the air emissions of a rail haul system are

[22]Eileen Brettler Berenyi, *the Materials Recycling And Processing Industry In the United States, 1995-96 Yearbook)*, Government Advisory Associates, Inc., 1995.

significantly less than long-haul trucks, a new landfill, or a waste-to-energy facility.[23] These factors combined with the difficulties of siting large landfills in an urban area where available, suitable land is scarce makes rail haul an attractive option. The Sanitation Districts are planning a rail haul transfer system based at the Puente Hills landfill,[24] that would include recovery of materials from the tipping floor prior to transfer (the Puente Hills Materials Recovery Facility), but no implementation has been initiated. It is possible to implement this MWPF in stages. The Sanitation Districts could construct the basic transfer building and implement the diversion activities immediately. Rail spur construction and intermodal transfer equipment could be added at a later time when closure of Puente Hills is imminent. Intensive materials recovery at the proposed Puente Hills MRF could equal the 46 percent diversion accomplished by the City of Sunnyvale MWPF discussed above.

Given the advantages discussed above, why hasn't rail haul been implemented in Los Angeles County? Part of the answer is the lack of full cost accounting for solid waste in the County. For example, the DEIR/DEIS[25] compares the estimated cost of rail haul ($50 per ton) to the estimated cost of landfilling ($20 per ton) at the proposed Elsmere landfill and concludes that the cost differential is too high. This, despite the presentation of information in the DEIR/DEIS that over 75 percent of the waste will arrive in transfer trucks. No cost for these transfer operations was considered.

The 19 transfer stations have a permitted capacity of approximately 20,000 TPD or 57 percent of the 1995 disposal requirement. The cost of transfer, which averages between $15 and $25 per ton, should be added to the disposal cost of most of the waste going to landfill to make any comparison of feasibility. The lack of a direct billing or full cost accounting system for solid waste obscures this issue.

[24]*Intermodal Facility and a Waste-by-Rail Disposal System Originating from the Puente Hills Materials Recovery Facility, Draft Environmental Impact Report*, Sanitation Districts of Los Angeles County, December 1994.

[25]Page 3-20, DEIR/DEIS.

Recommended County Actions:

- Encourage County Sanitation Districts to begin construction and operation of the proposed Puente Hills Materials Recovery Facility including rail transfer capability as soon as possible;
- Transfer haul combustible loads, as necessary, from the County's transfer facility, and assist in negotiating agreements for transfer of combustible loads from the proposed Puente Hills MRF and existing transfer facilities, sufficient to keep the two waste-to-energy facilities operating at MCR (see Chapter V, section C);
- Encourage diversion at the existing public and private transfer stations in the County, by such measures as a revolving low-interest loan fund for purchase of equipment or expansion of facilities, providing markets information and assistance in developing cooperative marketing activities, etc.
- Incorporate the cost of transfer operations and haul when comparing disposal fees at landfills.
- Develop a system of regional transfer stations that will serve the communities in the County to reduce collection truck travel and optimize waste management. Transfer stations in the system should include diversion and rail transfer capability.

H. MARKET DEVELOPMENT

The County continues to place its planning emphasis on the disposal portion of its integrated waste management strategy. The majority of the County's waste management resources are directed toward landfilling. The official policy of the State of California and the County state that 50 percent of the waste stream shall be diverted from landfills by the year 2000. Because diversion is a new approach to solid waste management, the County and the 88 cities should devote a larger portion of the planning effort and resources of the waste management activity to determining just where the diverted materials will go. As discussed in the materials markets trend description in Chapter VII and in Appendix J, recycling, which is the primary form of diversion, takes place only when the material collected by curbside or other programs is used to make a new product. This makes the manufacturers that utilize the recovered materials critical to diversion.

According to a recent report from U.S. EPA,[26] manufacturers that utilize recovered materials in their manufacturing process to make new products also produce economic and environmental benefits, including: creation of manufacturing jobs; creation of sales revenue and economic growth; reduction in air and water pollution; reduced energy and resource consumption; and reduction of the extraction impacts of developing virgin resources. In contrast to the "recyclers", collectors and processors, the manufacturers receive most of the economic benefits of recycling. For example, a ton of old newspaper is worth about $5 collected at the curb, $25 when sorted to specification, and $570 made into new newsprint. The addition of capitol and labor to the recovered materials through the recycling process creates value. Additionally, while jobs are created during the collection and processing of the materials, almost half of the total job creation occurs in the manufacturing phase. The U.S. EPA report uses the example of the processing of 15,000 tons of old newspaper annually; this creates 30 jobs in collection, 40 jobs in processing, and 75 jobs in the manufacture of new newsprint.

Given the economic trends in Los Angeles County, as discussed in Chapter V, the County would be well served by a policy that focused on the development of the manufacturing of new products aspects of the recycling process. The key to this development and the economic benefits it can produce is market demand for the recovered materials. It is a truism that when there is no market for a product, the economic activity associated with the product drops to zero. As discussed in the sections on recovered materials market trends, the industrial sector of the economy has made major investments in the use of recovered materials as feedstocks. There are many things local governments can do to support and assist industry in this. Some examples of specific programs that have been implemented were compiled by the Local Government Commission in the report *Capturing the Local Economic Benefit of Recycling*. The section of this report, Local Officials Are Playing a Critical Role, is reprinted in Appendix I. They boil down to two recommendations for the County:

- Establish a policy of purchasing and using products that are recovered, reprocessed or made from recovered materials; and

[26]United States Environmental Protection Agency, *Manufacturing From Recyclables: 24 Case Studies of Successful Recycling Enterprises*, No. 530 R95001, February 1995.

- Make industries that add value to secondary materials or use recovered materials in new products a high priority in the County's economic development program.

I. PUBLIC EDUCATION

A County of Los Angeles public education campaign is an essential part of successfully stepping into a proactive role in solid waste reduction/diversion efforts. The County's public education approach would vary by the type of audience. Audiences the County must reach include:

- Residents of the unincorporated areas (for whom the County provides collection services directly or on contract);
- The County public-at-large, including the residents of the 88 cities; and
- The commercial/industrial sector.

1. Residents of County Service Areas

A public information campaign directed to residents of the unincorporated areas that are served by County or County-sponsored collections would primarily convey practical information on "how to" and "why to" participate in source reduction and recycling efforts. The tools available include flyers or brochures distributed along residential collection routes or at central locations such as supermarkets; press releases to local newspapers, advertisers, and community newsletters; presentations to civic organizations; participation or sponsorship of local events; and so on. Spots and programs on radio and television, both commercial and public stations, are very effective. For example, Santa Monica has run extensive programs on waste diversion and disposal. Continual reminders of how and what to recycle are needed to maintain effective residential participation in recycling programs; the information may be developed and distributed by the County or by their contractors under County supervision. Whatever efforts are undertaken to reach this audience must be coordinated with the County-wide campaign discussed below.

2. County-wide Public Information Campaign

Each of the incorporated jurisdictions in the County has developed their own recycling/source reduction program, as outlined in their SRREs and implemented by the community. Each will have its own public information component to support the program. However, the County must develop a County-wide Plan that incorporates all of the SRREs (including the SRRE prepared by the County for the unincorporated areas). Preparation of this County-wide Plan is an opportunity for the County to also develop a coordinated public information campaign that enhances the efforts taken by each locality. The County's function in this campaign is that of cheerleader and role model. Highlights might include:

- Develop a model recycling program for all County offices, facilities and operations. Document the development of each type of program, including such factors as waste audits, program planning, costs, employee education, market development, and track program results. Use these "case study" model programs as training materials for private sector recycling/source reduction development projects.
- Develop a County-wide "reduce-recycle" theme advertising campaign. The campaign theme would then be used for all County public relations efforts and would be made available to local jurisdictions to support their efforts.
- County-wide media campaigns, such as public transit "remember to recycle" posters or broadcast media Public Service Announcement (PSA) spots.
- County-sponsored support programs, such as seminars for local recycling staff, a regional on-line materials exchange, and a County-maintained data bank on regional markets and market prices for recovered materials.
- Development of local media advertisements or public information materials that can be personalized by the local jurisdictions, such as a "home composting" ad or brochure that leaves room for the addition of local contact names, telephone numbers, and addresses.
- A County-wide program targeted to public and private primary and secondary schools that will supplement local school programs, such as a travelling theater show for specific age groups or County-wide art contests.
- Provide continual feed-back on how well this program is doing as is done in other public campaigns.

3. Commercial/Industrial Sectors

County efforts in this area are crucial. The commercial waste stream represents 32.3 percent of the overall waste flow in Los Angeles County; and industrial is 17.0 percent, for a total of 44.4 percent.[27] This fraction includes County government offices, agencies and service providers, as well as private businesses and multi-family housing. Without the cooperation of this broad sector, efforts toward significant reductions in the amount of waste requiring disposal are futile. The business sector has not embraced recycling as wholeheartedly as the public/residential sector (with some prominent exceptions, such as set recycling efforts in the film industry). This attitude on the part of business is understandable as 84 percent of the 212,252 employers in the County are small businesses employing less than 20 people. Small business are more apt to feel they cannot "afford" to recycle and do not understand how it can benefit their bottom line. Larger firms often get caught up in bureaucratic procedures similar to government agencies. The focus of the commercial/industrial/institutional sector is on manufacturing a product and selling it on the market, providing a service and bringing in new customers, or otherwise fulfilling their business aims and goals. However, the message that source reduction and recycling are part of "good business" must be conveyed.

Recommended County Actions:

- Convince businesses that source reduction and recycling, properly implemented, can reduce their operating costs. Make businesses aware of the value of their discards.
- Let the business sector (including County government) know that recycling is appreciated by their customers. Generating customer approval is good business.
- Promote local jurisdiction "waste audits" for businesses, provide technical support.
- Make businesses aware of the liabilities of their discards. Source reduction or elimination of hazardous wastes can pay off in reduced disposal costs. Additionally, under the Superfund law, what you threw away yesterday can come back to haunt you in the future.
- Make sure businesses (including County government) understand the consequences of not participating -- State fines (up to $10,000 a day) for not reaching 50 percent diversion impact everyone's taxes; new business and job creation opportunities are lost; and waste transfer and landfill costs will go up.

[27]Totals do not add to 100% due to rounding. *Source Reduction and Recycling Element (SRRE) for Unincorporated Los Angeles County*, County of Los Angeles, Department of Public Works, December 1991. See Appendix G.

J. PUBLIC POLICY INITIATIVES

The operative public policy that addresses solid waste management in Los Angeles County is the 1988 Action Plan, which, until superseded, has the force of law in the County. Much has changed in both Los Angeles County and in solid waste management in the last eight years. In fact, AB 939 requires that the County change its public policy to divert solid waste from landfills and document this change in an Integrated Solid Waste Management Plan. This plan has not been published, let alone adopted. In the past, the County has taken a leadership role in solid waste management -- it has provided abundant and cheap landfill capacity. It is time for the County to shift its public policy to the new reality, conservation and diversion, and supply the leadership for this new vision.

There are a number of public policy initiatives that the County could take to supply the leadership that 88 cities cannot supply. The programs that can be implemented to carry out these policies are discussed in the body of this report and its appendices.

Recommended County Actions:

- State that it is the County policy to provide the leadership in conservation of the County's resources and diversion of materials from landfills;
- Lead by example, set and achieve high diversion goals, (above 50 percent) for the unincorporated area and the County facilities;
- Establish variable rate direct billing with itemized cost elements for all generators in the unincorporated area;
- Establish an enterprise fund accounting system for all solid waste management in the County;

- Modify the tax structure in the County to provide incentives to divert materials and meet diversion goals and disincentives for not meeting goals;
- Minimize the landfilling of recyclable materials in County landfills by adoption of landfill bans;
- Declare a moratorium on the approval of new landfill sites in the County;
- Minimize the consumption of existing landfill space;
- Promote the development of facilities necessary to achieve additional diversion, such as composting facilities, MRFs, etc.;
- Establish enforcement that supports diversion;
- Establish requirements on private solid waste management firms that operate in the County to maximize diversion including mandatory recycling, variable rate billing, itemized cost element billing, reporting, etc.;
- Develop reporting and database system that support diversion;
- Develop information and technical assistance programs to support the cities and private industry in source reduction and diversion; and
- Work to establish organizational structures among the cities, Sanitation Districts and the County to coordinate and unify the reduction and diversion efforts.

APPENDIX A

APPENDIX A

PRODUCER RESPONSIBILITY OR TAKE IT ALL BACK

A. BACKGROUND

The basic principle of producer responsibility is that selling a product to someone else does not absolve the seller - manufacturer, wholesaler, or retailer - from the responsibility for the disposal of the product when its useful life is over. This concept has been discussed in Europe and the U. S. since the 1970's. The European Community (EC) began legislated enforcement of the concept with implementation in 1985 of the Liquid Food Containers Directive.

The German Packaging Ordinance was passed by the German Parliament in April 1991, about the time the EC started to work on a directive for all packaging. Two years later, France enacted the Eco-Emballages system and Austria enacted the Alsstoff Recycling Austria. The other EC countries adopted or are working on "take it all back" systems that are similar to the German system (e.g. Belgium), or differ widely (e.g. Britain). All of these systems have to meet the aims of the EC Packaging Directive that was adopted in 1995, i.e.:

- To reduce the overall impact of packaging on the environment; and
- To remove trade barriers and distortions of competition among EC members.

Over the next few years will see an effort to reconcile the national programs that are in place with the EC Packaging Directive. This will take considerable political energy. In the meantime, additional "take it all back" directives are being developed for batteries, electronic products and automobiles.

B. THE GERMAN SYSTEM

The German Packaging Ordinance has had a significant impact on that nation's packaging manufacturers; distributors, retailers, and consumer products industries. Industry has the

obligation to take back used packaging and ensure it is reused or recycled. This obligation applies to all packaging. The goal of the regulation is to reduce packaging waste by six to eight million metric tons annually, or 20 to 25 percent of the residential waste stream. Packaging currently accounts for half the volume and one-third the weight of Germany's residential waste stream.

The Ordinance is markedly different from the many North American attempts to control packaging in that it assigns the private sector the responsibility for reducing waste. The German Environment Ministry is adamant that suppliers of a product, not municipal governments, are obligated to take back product packaging.

The implementation of the Ordinance was divided into three phases; each phase focused on a different type of packaging.

The first phase of the Ordinance addressed transport packaging (mostly corrugated cardboard, but also barrels, canisters, cases, sacks, pallets, polystyrene, and shrink wrap) and went into effect December 1, 1991. It required that the 2.3 million metric tons of transport packaging used to deliver goods to retailers be returned for reuse or recycling.

The second phase addressed secondary or distribution packaging -- basically, packaging designed to get the product to the store and promotion packaging, including cartons, canisters, trays, and plastic bags -- and went into effect April 1, 1992. At that time, consumers were permitted to leave secondary packaging in stores.

The third, final, and most controversial and widely publicized phase addressed primary packaging -- i.e. the immediate covering for a product, such as bottles for wine, cans for coffee (sealed with plastic), cans, jars (for mayonnaise, mustard, caviar), aseptic boxes, blister packs, and tubes for tooth paste, etc. -- and went into effect January 1, 1993. Retailers were required to either provide facilities to take back waste packaging or to participate in a privately funded collection system that guarantees minimum recycling rates for specific packaging materials. If those rates were not achieved, the government threatened to impose deposits on a variety of

packaging types. Germans already buy 72 percent of their beverages in refillable glass and plastic containers that carry deposits of from 30 to 70 pfennings (US 18 to 42 cents). The packaging ordinance stipulates that the market share of refillable containers must not fall. By July 1, 1995, the Ordinance had been modified to require that 80 percent of each type of packaging material must be collected. Also, that least 80 percent of each material collected must be separately sorted for recycling.

Reluctant to become repositories for the country's discarded packaging, German retailers, along with 600 packaging firms, consumer products companies, and raw material suppliers, formed a company, Duales System Deutschland (DSD), that created a dual (hence, "Duales") system that was to be separate and distinct from existing municipal garbage collection services. DSD, a Bonn based enterprise, began initial implementation in July 1991, with pilot collection programs in selected regions -- including seven cities. By March, 1992, DSD had signed contracts in 138 regions of the country, serving 21 million people or 25 percent of the population. A goal was to serve 90 percent of German's 80 million people by 1993 was set and a nationwide system of drop-off facilities and collection programs for eligible packaging waste was established.

The DSD system was initially intended to completely replace municipal collection of packaging materials. That, however, led to accusations of DSD creating an illegal monopoly. Thus, its collection strategy was changed to encourage cooperative relationships between it and municipal haulers. Collection for the DSD is now provided by public or private haulers under a contractual agreement with DSD, with each community having a slightly different contractual arrangement, based on existing collection and recycling programs.

The basic DSD concept is to collect glass (sorted by color) and mixed paper at drop-off centers using "igloos." While igloos had been distributed in most regions of the country prior to DSD's existence, more containers since been strategically placed to serve about 500 residents per site. All other packaging materials are collected at curbside in yellow bins. It has been estimated that the implementation of this waste system will ultimately require about 200 sorting and processing facilities because of the increased volume of recyclable materials. The cost of

implementing the DSD system was originally estimated at 7 billion Marks (US $4.2 billion), with annual operating costs of 2 billion Marks (US $1.2 billion). DSD's operating costs for 1994 were about DM 3.3 billion, and costs in 1995 were forecast to be around DM 3.9 billion. Both are well above the original estimates. By 1995, the total network provided an estimated 18,000 jobs.

The DSD raises the revenue to pay for the facilities through the "green dot" system. Under this system, participating companies pay a licensing fee that varies according to the size and material of the package. With these licensing fees, the consumer products companies obtain the right to display the green dot on their packaging. Packages displaying the green dot are guaranteed a market by materials processors and, thus, effectively come with the warranty that they will be recycled. By April, 1992, DSD had sold 5,000 licenses to hundreds of domestic and foreign based companies. By 1995, this number had grown to more than 17,000. Because most of Germany's large retailers have threatened to provide shelf space only to those products carrying the green dot, DSD estimates that 80 percent of all packaging will have the symbol by the end of this year.

Companies using plastic and certain types of aluminum packaging must, prior to using the green dot, obtain additional take-back guarantees from trade associations. Because plastics are the most expensive material to collect and recycle, licensing fees for them are 25 percent higher than for other types of packaging and will soon increase by at least 50 percent. The average is two pfennings (a little more than a US penny) per container. Average consumer prices will rise by half a percent because the additional cost of this green dot licensing will be passed on to consumers. The DSD will thus cost an estimated $120 per household per year, and raise about $1.2 billion annually. Much of this DSD revenue will be spent on a multi-media campaign to educate consumers.

Consumer reaction has been positive to the option of being able to return packaging waste.

C. RESULTS OF GREEN DOT PROGRAM (DSD) TO DATE

The DSD program seems to be a success in terms of the German Packaging Ordinance's original goals. A recent study by a large German retailer concluded that secondary packaging in grocery stores has been reduced by up to 98 percent, or 51,000 metric tons annually. A random survey of 400 DSD members determined that 199 types of packaging materials (26 percent) had recently been entirely eliminated and that a quarter of all products they handle no longer come with any packaging. Of the 146 members that had formerly used plastic blister packs, only one still does. Polyvinyl chloride packaging, which had previously been used by 57 members, has been universally eliminated. Plastic foams also were abandoned after previously being used by 35 respondents. Paper and cardboard often are substituted for packaging that is difficult to recycle. A quarter of packaging materials used by respondents now contains recycled materials.

The DSD system, however, is very expensive and almost went bankrupt. The reasons for its financial difficulties are:

- The emphasis in on materials recovery with very high recycling targets - DSD has to insure that 64 % of the plastic packaging is recycled;
- Short implementation time - 18 months for the countrywide system;
- DSD is responsible for all collection and sorting costs and re-processors receive the material for free;
- DSD concluded unfavorable contracts due to the time constraints and, thus, its weak bargaining position; and
- Firms used the green dot label and did not pay or were late in paying their fees.

In the last year or so DSD has addressed these issues. Contracts have been renegotiated and controls on the use of the green dot tightened up. Also, starting in January 1996, re-processors have been paying the market price for materials.

The DSD system, with its green dot recycling guarantee, provides a financial incentive for industry to design packaging which is easily recyclable. However, it still has been widely criticized. Environmentalists and some politicians view it as an easy way out of more expensive requirements involving deposits and take back requirements for retailers. Other critics contend that the fees for the DSD system are not high enough to eliminate much of the throw-away packaging and that, despite the green dot, some materials, such as plastics, remain too difficult to recycle. Proponents of the DSD system counter that because packaging that is more difficult to recycle will incur higher processing costs, the system provides a built-in incentive for manufacturers to use materials which are easily recycled. They also assert that because the green dot licensing fee is based on the size of the package, it provides a reason for firms to use smaller packaging.

Additionally, DSD's educational campaign has been attacked for appearing to suggest that products bearing the green dot are environmentally friendly.

And, the rapid implementation of the DSD collection system has been blamed for putting large quantities of recovered materials on markets that were not capable of absorbing them. This has caused, it is claimed, the prices paid for these materials to drop and thereby jeopardize the entire recycling effort. While it is true that recovered materials prices have dropped in Europe and worldwide in the past year, it is highly unlikely that this is solely due to the DSD system implementation.

There is a perceived threat to the current prevalent system of returnable bottles, which is seen in Germany as one of the most effective ways to eliminate packaging waste. Such refillable containers would not be part of the DSD system and would not bear the green dot, and hence may be viewed as not being environmentally sound. To address the danger, the Ordinance stipulated that the market share of refillable containers must not drop below the current 72 percent for beer, water, soft drinks, juice and wine, or 17 percent for milk. If the market share goes below those levels, the exemption from mandatory deposits on all beverage containers will not apply. Many environmentalists are not satisfied with those quotas, contending that they preserve the status quo and do nothing to increase the use of returnable containers. Further,

because the returnable bottles favor local bottling and short transportation links, the EC may decide that this approaches a device to restrain trade. This could result in a major political battle.

APPENDIX B

APPENDIX B: DIVERSION ALTERNATIVES

In this Appendix, various technologies and management techniques for solid waste that have been applied in other U.S. communities are discussed. Frequently, examples of community experiences are provided along with a description of the approach to illustrate what practically can be accomplished (as opposed to theoretical diversion estimates). For some technologies, where sufficient operating experience across many facilities is available (such as waste-to-energy) specific examples are not needed.

A. SOURCE REDUCTION

Reduction at the source is the first of California's hierarchy of integrated waste management practices. Defined in AB 939 as "any action which causes a net reduction of solid waste" source reduction represents a proactive, front-end approach to waste diversion. In the SRRE* the County estimates that it will achieve a 4.3 percent diversion of the total waste stream by 2000 through source reduction. The Cities have similar goals. Section 18734.3 of the regulations lists a minimum source reduction alternatives in four categories:

1. Rate structure modifications;
2. Economic incentives;
3. Technical assistance and promotion; and
4. Regulatory programs.

Of these the County rated Rate Structure Modifications the most effective. Within each of the categories there are a number of specific programs that the County and the Cities could adopt and promote. The objective is to get the individual waste generators including the County and the Cities to reduce their waste generation. Seven strategies that waste generators should apply are:

1. Purchase products for recyclability and reduce the use of non-recyclable materials;
2. Reduce packaging and reduce the toxicity of packaging and products;
3. Increase the amount of recycled materials in packaging and products;
4. Replace disposable products with reusable products and products made with recycled materials;
5. Use materials and products more efficiently, i.e. print on both sides of paper;
6. Purchase products with longer useful lives, i.e. 60,000 mile tires, and products designed to be repairable; and
7. Reduce yard waste by on-site management, i.e. "grasscycling".

The key to source reduction is modifying individual behavior. Policies, programs, and incentives that support source reduction goals have been implemented in the communities that are most successful in diverting waste from landfills. These alternatives work synergistically with recycling programs to maximize diversion. This can be seen in the Seattle, Washington case study discussed in Appendix D.

The sections below focus on two types solid waste management approaches that can be used to increase diversion: collection techniques and processing technologies. The collection techniques discussed in Section A are applicable to diverting many types of materials, and bring them into the processing facilities. The processing facilities discussed in Section B can also be applied to different waste stream materials. In order to avoid "double counting" waste stream material diversion achievable by application of these processing technologies, specific materials are discussed separately under each technology heading. These technologies have been applied to divert the Los Angeles waste stream in Chapter VII.

B. COLLECTION

The techniques used to collect MSW have an impact on the diversion potential. Once recyclable materials are mixed in with materials that are potential contaminants, they are harder

to recover. For example, when food waste from a supermarket is placed in the same container as old corrugated containers (OCC), then collected in the same truck, the OCC is contaminated by the food and is less recyclable. The food-contaminated OCC is unacceptable as feedstock to a paperboard manufacturing plant, but could be composted to a lower-value humus product.

The general approach is to identify specific materials in the residential, commercial and industrial waste streams that contain recyclable materials or that should be collected separately to maximize recycling and diversion. Optimization of collection systems and routes has a large economic return for both the public and private sectors because collection generally consumes about two-thirds of every solid waste management dollar (see Appendix E).

Techniques that have potential to increase diversion and improve the quality of recovered materials include the following:

1. Intensive Residential Curbside Collection

This approach adds residential mixed paper (junk mail, OCC, boxboard, phone books, kraft bags, and magazines and catalogues) and textiles to the standard set out and collection. Separate set out and collection of yard waste, if not used, should be added. This alternative may be coupled with new collection techniques such as the split container and truck system used in Visalia, California; or the once per month collection of recyclables used in Seattle, Washington. Based on a survey of 19 California programs[1] the average household set out 189 pounds of mixed paper (excluding newspaper) in 1994. Based upon the addition of mixed paper to County-wide recycling collection to 2,989,552 households, the additional diversion at this rate would be an estimated 283,000 tons. Seattle, Washington averages over 100 pounds per family higher in residential mixed paper collection than the 19 California programs. If an intensive program such as Seattle's was implemented County-wide, an estimated 383,000 tons per year could be diverted. This is only 10 percent of the estimated total paper disposed of in the County in 1994.

[1] *Resource Recycling*, June 1995.

Table C-1. Recovered Paper Volumes from Selected Curbside Recycling Collection Programs
(Pounds per Household per Year)

Program	Households	Paper Fraction[1]	ONP	RMP	OMG	OTD	OCC	Total
Barrie, ON	27,000	59%	169	16[2]	[3]	[3]	44	229
California[4]	947,669	85%	241	151	[5]	[5]	38	430
Evansville, IN	42,000	81%	143	46	[5]	[5]	[6]	189
Goldsboro, NC	11,000	65%	[3]	[3]	[3]	[3]	[3]	251
Green Bay, WI	31,300	75%	[3]	[3]	[3]	[3]	[3]	327
London, ON	83,000	70%	271	6[2]	[3]	[3]	15	292
Portland, OR	125,500	81%	321	73	28	[5]	54	476
Seattle, WA (North)	69,538	74%	335	214	[5]	6	77	632
Seattle, WA (South)	66,640	76%	274	198	[5]	5	82	559
Vancouver, WA	15,524	82%	258	250	4	[5]	37	549

ONP – newspaper
RMP – residential mixed pper
OMG – magazines
OTD – telephone directories
OCC – corrugated cardboard

[1]Of total volume of recyclables collected by curbside recycling collection programs.
[2]Includes only OCC; household fine paper is collected with ONP.
[3]Collected with ONP, shown in Total Column.
[4]Summary of 19 programs that range in size from 10,000 to 275,000 households.
[5]Processed with residential mixed paper.
[6]Small pieces of OCC accepted with RMP; large OCC is not accepted.

Source: *Resource Recycling*, June 1995.

Table C-1 shows mixed paper recovery from programs in 12 cities. The mixed paper is broken into its components: (1) newspaper - ONP, (2) residential mixed paper - OMP, (3) magazines - OMG, (4) telephone directories - OTD, and (5) old corrugated containers - OCC. The cities vary in size and results; however, all show a significant increase in paper recovery over newspaper alone. In 1994, Ecodata, Inc. conducted a survey of 60 randomly selected cities with curbside programs.[2] The diversion rate for the curbside programs averaged 13.4 percent, with a range of 3 percent to 34 percent. Eight cities were identified as high achievers with 20 percent or more diversion: Daytona Beach, Florida; Elmhurst, Illinois; Hoffman Estates, Illinois; North Las Vegas, Nevada; Paramus, New Jersey; Port Huron, Michigan; Stamford, Connecticut; and Valley Stream, New York. Five of the eight cities collect mixed paper at the curbside.

A number of communities have added textiles to their curbside collection programs. These include: Bloomfield, Connecticut; Windsor, Connecticut; and Ann Arbor, Michigan. In October 1994, St. Paul, Minnesota expanded an existing pilot program that collects textiles and reusable items to a city-wide service. These materials have accounted for 1.8 percent of St. Paul's curbside collection.[3]

2. Wet-Dry Collection

Wet/dry collection originated in Europe. The system has the waste generator separate waste into either two or three categories and use two or three bins. The two-bin system is a wet/dry separation. The two streams are collected separately and are processed by different systems. Dry materials are processed at a materials recovery facility (MRF) and the wet fraction is composted. The three-bin system adds a residue bin that is collected separately for disposal. Wet/dry collection has application in both residential and commercial sectors. Applied to the residential sector, recovery well above the 50 percent level has been demonstrated. Santa

[2] *Resource Recycling*, October 1995.

[3] *Resource Recycling*, April 1995.

Barbara County[4] conducted a pilot program with several different collection schemes; both two-bin and three-bin systems. The diversion rates ranged between 57 and 73 percent, with an average of 65 percent. The project recognized that high rainfall had increased yard waste; adjusting for this factor, the average diversion in the Santa Barbara pilot program was 58 percent. A number of communities in Canada and the United States have implemented full-scale wet/dry programs. These include: the City of Guelph and the City of St. Thomas, Ontario; Mackinac Island, Michigan; and East Hampton, New York.

Other communities are separating selected organic waste fractions for collection and processing. These programs target food waste from restaurants, supermarkets and food processing companies for composting. Some programs also include soiled paper, paper mill sludge and other organic materials in the composting mix. Commercial collection of food waste from restaurants, supermarkets and other food service establishments that are collected on a single route could be delivered to a composting facility. The non-food waste from other commercial establishments such as offices then would be free of food contamination and more easily recovered. For example, waste from some office buildings contains 90 percent paper. Without the addition of other materials during collection, waste paper from offices is highly recoverable. There are many examples of high level commercial/industrial waste diversion, ranging from 60 to 90 percent. These include major U.S. and California firms, such as AT&T, IBM, Fetzer Vineyards and Transamerica Corporation.

Separate collection of food waste is a rapidly expanding technique. Programs have been implemented in Freehold, New Jersey; Calgary, Alberta; Jasper National Park, Alberta; and Burlington, Vermont. A number of food market chains are interested in the approach and have initiated programs including Shop-Rite in five states, Safeway in Ontario, and Stew Leonard's in Connecticut. In California, Vons has implemented a program with Community Recycling and Resource Recovery, Inc. This program manages food waste from all 325 Vons stores. The food waste collected in this program is composted at CRRRI's facility in Lamont, California.

[4] *The Santa Barbara County Pilot Waste Collection Project*, Final Report, April 1994.

3. Construction Waste

During construction projects, the general contractor usually provides a roll-off box that is used for waste from all subcontractors on the site. The materials in the roll-off are mixed as a result. If subcontractors had to remove their own waste, or if the general contractor provided separate containers, then lumber from the carpenters, gypsum from the drywall contractor, asphalt shingles from the roofer, and other specialized materials from individual trades would be separately collected and would be recyclable. This is currently being done by Cornerstone Material Recovery, a private firm in the Chicago, Illinois metropolitan area and is expanding to other cities in the United States.[5]

4. Comprehensive Drop-off Centers

To augment other collection alternatives, a system of centers designed to accept all types of waste and recyclable materials will divert additional material. Some of these drop-off facilities accept reusable items such as building materials and furniture, household hazardous waste (e.g., paint, batteries, household cleaners), used oil, auto parts, appliances, yard waste and refuse. Urban Ore in Berkeley, California is an example of a usable material drop-off; it has been operating since the early 1970s. Champion Paper, Inc. has established a system of 1,000 drop-off centers in Houston, Texas. Champion operates these centers under a 20-year contract to collect paper for their Houston plant.

At a drop-off facility, reusable and recyclable items could be accepted at no charge, while refuse requiring disposal could carry a small charge. Fairfax County, Virginia operates a large multi-material drop-off adjacent to its transfer station. The Fairfax facility accepts all the regular recyclable materials, yard waste, white goods, used oil, and wood; all of which are recycled. In addition, conveyors are provided to accept bagged waste and a conveyor transfer system for bulky non-recyclable materials. The facility is staffed to assess fees for larger loads from residents and small commercial operators.

[5] *Biocycle* Magazine, Pages 62-63, August 1992.

C. PROCESSING FOR DIVERSION

1. Materials Recovery Facilities (MRFs)

Material recovery facilities (MRFs) are designed and built to process a variety of solid waste streams. These include: (1) source separated materials from curbside collection or drop-offs, (2) commercial waste with high levels of recyclable materials such as office paper, (3) the dry stream from a wet/dry collection, (4) selected construction and/or demolition (C&D) waste, and (5) mixed municipal solid waste. The source-separated materials facilities are most commonly known as MRFs, commercial mixed waste facilities are often referred to as "dusty MRFs," and C&D or mixed MSW facilities are called "dirty MRFs."

The objective of all MRFs is to recover materials from the waste stream by separating them into marketable commodities. For example, glass is separated from other containers and contaminants, then sorted by color (amber, green and clear). The product is a clean, color-sorted glass that meets the glass manufacturing industry's specifications for glass cullet used to manufacture new glass products. The processes used by a MRF to accomplish these separations can be low-tech (relying primarily on hand-sorting) or high-tech (utilizing mechanical equipment as well as hand-sorting as needed). The materials processed and marketed by MRFs depend on the MRF feedstock.

Source-separated materials MRFs generally include all types of containers (glass, aluminum, steel and plastics); plus various types and grades of paper including newsprint, office paper, mixed paper, corrugated cardboard, etc. In the source-separated MRF, usually only PET and HDPE plastic containers are sorted, although other resins may be recovered. Technology now exists to mechanically separate plastic containers by resin and color; the identification of these are made using a variety of sensors employing x-ray, infra-red and other electromagnetic spectra. The prototype of this machinery is installed in Salem, Oregon and operates at 1,250 pounds per hour. Development of the prototype resulted from Oregon's legislation requiring that all rigid containers be refilled, be recycled or contain recycled material. This is an example of policy driving technology development and implementation.

A national survey of MRFs completed at the end of 1995 identifies and describes 386 facilities, 90 percent of which were in operation or under construction at the time of the survey.[6] No transfer stations with "dump and pick" operations are included in the current MRF list, an indication of the maturity of the MRF technology.

MRFs have the potential to process and market a significant portion of the solid waste stream in Los Angeles County. Even though there are an estimated 200 facilities which do some processing presently operating in Los Angeles County, additional facilities will be needed. MRF processing is an integral part of the strategy recommended for Los Angeles County to implement a diversion-oriented policy that achieves or exceeds the 50 percent goal. The diversion projections discussed in Chapter VII are predicated on the following assumptions:

- Intensive residential curbside collection is instituted County-wide
- Curbside collection is provided to single-family households in the County except those rural areas where population densities do not warrant it;
- Curbside collection is supplemented by a system of comprehensive drop-off facilities, particularly in rural areas not served by curbside collection, and multi-family dwellings;
- Private haulers are mandated to provide recyclable material collection to their contract accounts (businesses, industries, institutions);
- High participation rates for all forms of diversion collection are achieved by high levels of public information and enforcement of mandatory requirements;
- Materials processed by MRFs include: glass, steel and aluminum food and beverage containers; HDPE and PET plastic containers; all clean paper (newsprint, magazines, corrugated cardboard, mixed paper); and textiles;
- Potential contaminants such as food waste are collected and processed separately from commercial/industrial waste;
- MRF residue (non-processible material sent for disposal after processing) is 15 percent; and
- Commercial/industrial wastes are processed in a MRF prior to disposal.

[6] *The Materials Recycling and Processing Industry in the United States*, Eileen Brettler Berenyi, Governmental Advisory Associates, Inc., 1995.

2. Composting Facilities

Composting is defined as the bacterial decomposition of organic materials. All of the composting technologies commercially available today rely on aerobic decomposition (that is, utilizing bacteria that live in the presence of oxygen). Anaerobic digestion of waste stream materials (composting that utilizes organisms existing in an oxygen-free environment) is still in development and is not considered further in this report. Composting reduces the quantity of incoming organic material by about 50 percent by weight, through the loss of moisture and production of carbon dioxide during the decomposition process. When non-digestable materials such as metals, plastics and glass are present in the feedstock, a residue will result. The quantity of residue depends on the quantity of non-compostable material in the feedstock.

During the composting process, high temperatures generated by bacterial activity serve to kill pathogens as well as most seeds and spores. Processing can be relatively low-tech, such as windrow piles that are turned occasionally to maintain proper moisture and temperature for bacterial activity, to high-tech, totally enclosed and mechanized reactors that have been applied to a variety of waste feedstocks. All of the technologies discussed below are focused on processing quantities diverted from the waste stream, as opposed to home composting approaches. Home composting can divert residential yard and food wastes (except meat and dairy wastes). Composting, by its nature, produces odors which must be controlled.

Markets for compost derived from components of the MSW stream are still developing. Composting is used to convert organic material into a usable soil amendment. Compost can be used as mulch, or can amend clay or sandy soils to improve moisture retention and friability. The market for this material is the same as the market for peat moss, including farmers, home gardeners, landscapers, nurseries, potting soil manufacturers, etc. The industries and farms that can utilize these materials in significant amounts are tentative about risking their livelihood on a relatively unfamiliar product. Considerable education efforts, demonstration programs, and scientific studies are still needed to open these markets to the very large amount of materials composting is expected to divert from the waste stream.

a. Yard Waste

Yard waste materials are the most common compost feedstock. All yard waste materials (also called "green waste") must be diverted from disposal in California. Many of the Cities in Los Angeles County collect yard waste separately. In the City of Los Angeles, yard trimmings from the curbside collection program are used by San Joaquin Composting (SJC) as bulking agents for composting the City's biosolids (see below) at SJC's facility in Lost Hills, California. This City program is known as Full Cycle Recycle (FCR). FCR presently diverts all biosolids generated by the City of Los Angeles, and all yard trimmings collected at curbside. As of the beginning of 1995, about 250 tons per day were delivered to SJC, and the remaining material was either composted elsewhere or used as mulch. As the curbside collection program continues to expand, all future yard trimmings collections will be incorporated into the FCR program, thus diverting all residential yard waste generated in the City from disposal. The FCR plan calls for the creation of local facilities that will play a major role by serving as yard trimming drop-off and transfer to SJC sites, and, after processing, centers for bagging and distributing the product, "TOPGRO." TOPGRO is presently bagged at the Lost Hills facility and marketed by an SJC subsidiary, Organix Supply, Inc. TOPGRO is sold by local outlets, such as Fedco membership department stores and Armstrongs' -- The Home and Garden Place. The compost is also used by City agencies in maintaining City-owned parks, gardens, and golf courses, and for facility landscaping.[7]

The green waste fraction of yard wastes (i.e., leaves, grass clippings, weeds, small prunings) can be composted alone or in conjunction with other waste materials, such as biosolids, food wastes, contaminated paper that otherwise cannot be recovered (such as disposable diapers), and similar organic fractions of the waste stream. An estimated 100 compost facilities were in operation in California as of May 1995.

Yard waste is also diverted from disposal through source reduction approaches, specifically, the "don't bag it" method of leaving grass clippings on the lawn to provide nutrients

[7] "Co-Composting in Los Angeles Optimizes Resource Management," *BioCycle*, December 1994.

and reduce waste, and home composting. In Alameda County, California's Master Composter program has trained 39 Master Composters, who, in turn, have trained over 5,000 home composters in the County. In 1993, 6,600 home compost bins were sold by the County program to homeowners. A follow-up survey showed 94 percent of the recipients regularly used their bins. Previous survey work in Alameda County demonstrated that each home compost bin diverts approximately 600 pounds of compostables each year. Based on the participation rates, the County estimates that the 1993 bins divert 1,800 tons from the County waste stream. San Diego County has established a Master Composter demonstration center at Quail Botanical Gardens. The Master Composters trained at the Center commit to 40 hours for teaching the knowledge and skills they have gained to others.[8]

In addition to use as a bulking agent for composting, woody waste (i.e., tree limbs, branches, brush) can be chipped and used as mulch or wood fuel (as discussed above). The Public Utilities Commission's deregulation of the electric utility industry caused a number of wood-waste-to-energy plants to close in California; as a result, the fuel market for wood chips is limited at the moment. Because of a medfly quarantine in Southern California, all yard trimmings have to be processed within the quarantined area before they can be transported elsewhere. Chipping and composting interfere with medfly reproduction.

Yard wastes lend themselves to low-tech composting operations, because the low nitrogen content means relatively low potential for odors during the composting process. Some materials, such as grass clippings, are high-nitrogen and must be handled more carefully to manage odor. Larger facilities may roof over the composting area, the pads may be paved, and some facilities enclose the initial composting area to avoid operational problems, such as excessive moisture from precipitation, over-drying from winds, or materials blowing off-site. Each "improvement" to the system adds to the overall cost.

In January 1995, the California Integrated Waste Management Board (IWMB) issued a ruling that shredded yard waste could be used as alternative daily cover on landfills and that this

[8] "Mastering the Way to Home Composting," *BioCycle*, January 1994.

use would count toward achievement of the 50 percent diversion goal. This reduces the incentives to develop markets for compost and mulch and consumes landfill capacity. The Natural Resources Defense Council (NRDC) initiated a lawsuit against the IWMB. The NRDC contended that this practice is not recycling or diversion, but landfilling. In February 1996, the Sacramento County Superior Court ruled against the IWMB. IWMB has appealed.

California Futures/Global Futures estimates that less than two percent of the potential agricultural demand of 10.6 million tons of compost per year is utilized.[9] Policies in the State and County should provide incentives to meet this potential demand.

b. Food Waste

Composting of food wastes is more problematic than yard waste, because of the potential for generating odors and attracting birds, rodents, and insects. Consequently, food waste composting is generally carried out in enclosed vessels (in-vessel or static-pile systems) during the first stages of decomposition. The later stages of decomposition can be carried out in windrow-type operations that are used for yard wastes. As discussed previously, a number of food waste composting project are operating in the U.S. These include school programs in New Hampshire, Freehold, NJ, Calgary Alberta, Minneapolis-St. Paul, MN, and the Von grocery stores project in Southern California.

It should be noted that food waste is collected, cooked, and used as hog and other animal feed in some parts of the country. In Florida, Walt Disney World has been sending five tons per day of food waste to Kenny Camp Farms since 19092. Two companies are actively marketing processing equipment to make feed pellets from food waste. However, markets are not readily available in Los Angeles County.

The product resulting from food waste composting is higher in valuable nutrients than yard waste compost. The product can be utilized as a fertilizer in addition to its soil amendment

[9]California Futures/Global Futures, *Agricultural Markets for Compost and Mulch: Costs, Benefits and Policy Recommendations*, December 1993.

properties. Because of the higher nutrient content, food waste compost has a higher market value.

c. Biosolids

Biosolids are also referred to as sewage sludge; this material is the solids portion resulting from wastewater treatment. Properly conducted composting processes reduce the pathogen contents to safe levels. The U.S. EPA has published regulations concerning composting (and landspreading) of biosolids (Clean Water Act, Part 503). The Part 503 requirements specify both the process parameters (time, temperature, moisture, etc.) and application limits depending on the product quality.

Because of the high moisture content of the biosolids entering the compost process (usually biosolids have been dewatered but are still 50 to 80 percent water) and the potential for odors, biosolids composting is initially conducted in enclosed vessels. The nearly-completed compost can mature in windrow piles.

Biosolids compost is, if made from uncontaminated feedstocks, a high quality soil amendment and, if properly marketed, will sell easily. In 1994 there were 201 operating biosolids composting facilities in the U.S. and another 117 under development.[10] Of the total 318, a number of commercial biosolids compost products are successfully marketed, including Philadelphia's EarthGro and the Maryland Environment Service's COMPRO, which sells in bulk to developers for $17 per ton and is bagged for consumer sales.

The City of Los Angeles' Full Cycle Recycle program provides feedstock to the TOPGRO manufacturer, as discussed earlier. In addition, Wheelabrator (Biogro) has proposed a facility with capacity for 500 TPD biosolids and 1,000 TPD other organics. This facility is planned for the Antelope Valley.

[10] 1994 Biocycle Biosolids Survey, *BioCycle*, December 1994.

d. Combination Feedstocks (including manure)

One example of a combined feedstock approach is being implemented at the Zoo in Griffith Park. The Griffith Park Composting Project, undertaken by the City of Los Angeles Biosolids Management Division with the Departments of Public Works and Recreation and Parks, will compost Zoo manure with biosolids and green trimmings from the park. If the current demonstration project is successful, a permanent facility will be built. The compost will be sold as a specialty product under the TOPGRO label.[11]

Combining feedstocks requires the compost processor to tailor the facility design, operations and equipment to the needs of the more problematic materials, such as manure. Enclosed buildings, compost vessels, and process air cleaning equipment (to reduce odor emissions) are all needed to reduce environmental impacts of these facilities. Combining feedstocks, however, allows the operator to "design" the end product to meet the specifications of a particular market, including balancing nutrient content, moisture, degree of stabilization, and particle size.

e. Mixed MSW

There were 17 mixed MSW composting facilities operating in the U.S. as of January 1995.[12] However, mixed waste composting is still in the development stage. Most facilities operate at a small scale in order to allow strict control of the waste entering the system. The largest facility in that list that is still operating is the Bedminster BioConversion system in Sevier County, TN. This plant started operation in 1992 and will process 200 TPD when the current expansion is complete. The systems used are high-tech, and in most approaches, the waste must be pre-processed to remove potential contaminants (glass, plastics and other inerts, and items with toxic components such as batteries) so that the resultant compost is low in chemical contaminants.

[11] Reba Fabrikant and Ray Kearney, "CoComposting in Los Angeles Optimizes Resource Management," *Biocycle*, December 1994.

[12] *Municipal Solid Waste Composting: A Status Report*, prepared by GBB for the Solid Waste Association of North America (SWANA), April 1995.

The markets for compost made from mixed MSW have so far been limited. The mixed waste composting process can result in a product that meets the EPA's Part 503 standards for biosolids compost; however, of the 17 operating facilities only one is successfully doing so. Both product quality and market development is needed. It should be noted that the Sevier County, Tennessee facility, which accepts 150 TPD of solid waste and some biosolids, has been successfully marketing its product to agricultural and horticultural users since 1992.

The amount of materials that can be diverted by composting programs differs by feedstocks. Assumptions used in calculating composting diversion are:

- The County bans disposal of all green waste, resulting in 95 percent of this material diverted from disposal. Most will be composted; woody waste will be chipped and used as mulch or as a bulking agent for biosolids composting.
- Food waste is not readily separated and collected from residences, because the material must be collected daily to avoid odor problems. Therefore, the target group for food waste composting would be large producers, such as canneries or other food processors, restaurants, and institutions. The target group is part of the commercial waste stream, where food waste is approximately 13 percent of the waste. Eighty percent of this is projected to be separately collected and composted.
- No biosolids should be landfilled in LA County. The current composting efforts should be expanded to provide capacity for all biosolids produced by wastewater treatment plants. Composting can be supplemented by landspreading programs in some areas of the County.
- Special projects are developed for unique feedstocks (such as LA City's Zoo manure project). These waste streams are too small to impact diversion rates County-wide.
- Mixed MSW composting projects are envisioned as part of Level 3, as discussed in Chapter VII, for residential waste not collected separately.
- Compost markets need to be developed to accommodate the feedstocks listed above before any further compost products could be considered.

4. Construction And Demolition Waste Facilities

With construction and demolition (C&D) materials amounting to as much as 30 percent of municipal solid waste, diversion through C&D recovery operations conserves large amounts of landfill space and adds years of useful life to landfill facilities. The City of Los Angeles calculates that nearly 15 percent of the solid waste stream is construction and demolition (C&D) materials. In some Southern California jurisdictions, C&D materials represent almost half of the total waste stream.[13] C&D materials generation is dependent on economic activity in the construction and building fields. Also, natural disasters can significantly increase the amount of C&D material in the waste stream.

The three basic categories of recoverable materials within C&D are inert materials, shredded wood products, and ferrous metal. Recovered inert materials, such as asphalt, concrete, dirt, rock and brick, are used for land reclamation, landfill final cover, fill for roads and airports, embankments, road base and subbase, aggregate for filter layers in landfills, French drains and bridge abutments, and asphaltic concrete. Uses for shredded wood include landfill cover, boiler fuel, animal bedding, composting bulking medium, pulp mill feedstock, and raw material for particle board. Recovered ferrous metals are used in remanufactured steel.

There are two basic types of facilities that process C&D materials. The first type accepts only clean loads of a single material such as concrete, asphalt, or wood. Processing usually includes size reduction with a hammermill or shredder, followed by sizing through a trommel screen or vibrating deck screen. Some manual sorting may be required to ensure the highest possible quality in the end product.

The second type of facility processes mixed C&D material. The material is brought to a tipping area, usually in a dump truck or roll-off box. Large pieces of materials, such as concrete, wood and metal, are pulled from the pile for processing. The remaining materials are fed into a mechanical processing system.

[13] *Business Recycling and Waste Reduction Guide*, The County of San Bernardino Solid Waste Management Department and The Cities of San Bernardino County.

The steps and equipment involved in mechanical separation and size reduction of C&D waste are generally very similar. Because many systems contain mobile equipment, the configuration of the machinery may be revised as characteristics of the feed and products change. Processing systems typically use trommel, disc or vibrating flat-bed screens to separate rock and soil. Density separation (e.g., pneumatic or hydraulic sink/float operations) is then used to divert wood scrap from heavier fractions. After wood scrap is size reduced though a hammermill or grinder, the material is often subjected to magnetic separation to remove the metal fraction.

Depending on the incoming waste stream, C&D processing facilities can range in size from under 50 tons per day to well over 2,500 tons per day. Cyclean, Inc., an asphalt recovery plant in Los Angeles, has kept over a million tons of asphalt out of the landfill in the last seven years and has saved the City $10 million.[14] Cyclean uses a microwave technology to make hot mix from 100 percent recycled asphalt. In addition to old pavement, crumb rubber from old tires can easily be incorporated into the Cyclean asphalt. The Cyclean product is sold at a discounted rate to the City of Los Angeles.

Pallets and dimension lumber are also reusable. A survey completed by *Pallet Profile Weekly* in December 1993 revealed that 70 percent of all pallets received for recycling are repaired for resale. Only one percent of the pallets are disposed in landfills.[15] The remainder of the pallets are dismantled for repair supplies, or ground into chips for use as boiler fuel, mulch, animal bedding, or particle board furnish. Guadalupe Landfill, in San Jose, California, has taken an innovative approach to managing the high percentage of redwood materials it receives from demolition projects. New World Furniture, an affiliated company, separates and reprocesses the redwood material, then an on-site carpenter re-works the wood to create home and garden items. The company grinds the unsuitable material to a 2-inch minus size, and markets this redwood mulch through Valley's Pride Organics, a Guadalupe Landfill division. In Portland, Oregon, the number of wood processing facilities jumped from three to eleven in

[14] "Paving with Recycled Asphalt," *BioCycle*, September 1994.

[15] Roger Guttentag, "Making Recovery Pallet-able," *Resource Recycling*, November 1994.

1990. Currently, recycling facilities in the area handle 100,000 tons of wood each year.[16] Most of these facilities are now charging nothing for clean, source-separated wood and are selling it for $20.00 to $45.00 per ton.

The diversion potential of C&D recovery operations were well demonstrated in the 94.5 percent recovery rate experienced by the City of Los Angeles and the Los Angeles Sanitation Districts after the Northridge earthquake. Within a month of issuing a contract, a C&D waste processing line was in place at the landfill. From October 1994 through March 1995, the program diverted over 47,437 tons of dirt and 41,873 tons of concrete from landfill disposal.[17]

Based on the above discussion, and the fact that there is ample inert landfill capacity for non-processible C&D wastes, 100 percent of C&D materials should be diverted from disposal in Class III landfills.

5. White Goods

White goods are large appliances such as dishwashers, refrigerators, etc. These materials contain high-quality steel and are recyclable through existing scrap industries. In 1994, the CIWMB database calculation indicates a total of 36,206 tons of white goods were landfilled from MSW generated in the County. This tonnage should be diverted from disposal in the future, either through separate bulk waste collection programs or separated at the transfer station/landfill.

6. Tire Recycling

As material recovery technologies continue to develop, many successful methods of recycling used tires have emerged. In addition to being retreaded for resale, old tires have been successfully diverted from landfill disposal through use as fuel, playground and athletic

[16] Randy Woods, "C&D Debris: Construction & Dismantling?," *Waste Age*, April 1994.

[17] Janet E. Coke, "Recycling Program Diverts Debris from Earthquake Cleanup," *Public Works*, June 1995.

field subbase, reroofing supplement, material for irrigation channels and other civil engineering applications, road subbase, plastics filler, composting supplement to prevent excessive compaction, and as an additive in modified asphalt. One recent estimate predicts that by the end of 1998, market demand for used tires will exceed the amount generated annually.[18]

Because tires have a high Btu value, they can be processed into Tire Derived Fuel and burned with other solid fuels, or they can be fed whole into cement kilns where they serve as fuel and as a source of constituents needed in the manufacture of cement. A report by the CIWMB notes that the consumption potential of burning shredded tires -- only in cement kilns located in California -- is nearly 25 million tires per year, which exceeds the estimated 21 million waste tires generated annually in California.[19]

Processing tires into crumb rubber for use in asphalt and other applications has significant potential. In particular, there is a huge, multi-billion dollar market for this material as a plastics filler. Overseas markets for tire chips for processing into crumb rubber for new tires is growing as well. BAS Recycling built a crumb rubber plant in San Bernardino, California, that has processed over 1.5 million tires to date.[20] BAS received a $100,000 grant from the CIWMB to transform recycled rubber into playground matting. Shredded tires also have been utilized in construction of drainage systems, retaining walls and other civil works, including landfill construction.[21]

Recovery of tires from the solid waste stream is primarily already handled by companies that market new tires at retail or wholesale, by managers of large fleets, and through such local government programs as bulk waste collection and cleanups. Problem tires are those resulting from illegal dumping or those that get buried in with the regular waste (in roll-offs, for

[18] David Riggle, "Finding Markets for Scrap Tires," *BioCycle*, March 1994.

[19] *Tires as a Fuel Supplement: Feasibility Study*, California Integrated Waste Management Board, January 1992.

[20] *Resource Recovery Report*, July 1995.

[21] *Resource Recycling*, October 1995 and *World Wastes*, September 1995.

example). Because the markets are so promising, the County should work with a manufacturer/exporter(s) to develop facilities and a bounty system to attract tires to market and away from disposal. It is assumed that, coupled with the existing systems, new tire programs, while desirable and effective, will not divert sufficient materials to affect the overall waste diversion rate for LA County.

APPENDIX C

APPENDIX C: LANDFILL CAPACITY CONSERVATION TECHNOLOGIES

Conservation of landfill capacity is a rapidly developing field. Getting the most use out of existing, permitted landfill airspace is particularly urgent in those areas where population densities make siting new landfills difficult, such as the East Coast of the United States, or where the geology is unfavorable (e.g., Florida). Consequently, most of the experience in applying techniques to conserve landfill capacity is from these parts of the country. However, it should be noted that experience with landfill conservation has also been gained by private landfill operators interested in obtaining the maximum amount of tipping fees for their permitted capacity. They, too, are obviously better off placing waste in their airspace rather than cover dirt.

Some techniques are available commercially and others are in development that conserve landfill space and thereby reduce the need for siting new landfills. The first three approaches described below are various Alternative Daily Cover (ADC) technologies that reduce the amount of airspace normally filled with dirt. The remainder are operational changes that follow placement of more waste in the available space. A CIWMB-funded study released in May 1995 noted the value of utilizing these techniques. Some of these techniques can be combined to increase savings (e.g., ADC with baling).

Secondary compaction in large landfills is also a conservation factor. Secondary compaction will occur as lifts of waste are layered upon each other. Fresh Kills Landfill, that has served New York City since 1948, is billed as the world's largest landfill. It covers 2,800 acres and presently accepts 13,000 tons per day. In some areas, the waste is piled 20 stories high.[1] Fresh Kills Landfill reports an in-place density of 1,800 pounds per cubic yard after settlement.[2]

[1] "Environmental Quality Shows Gains and Declines Since 1970, a Report Finds," *New York Times*, December 5, 1995

[2] Anne Magnuson, "The Economics of Landfill Compaction," *MSW Management*, November/December 1992.

1. Alternative Daily Cover (ADC)

The functions of daily cover are to: prevent windblown debris, reduce the amount of precipitation seeping into the filled area, suppress odors from decomposing fill, and deter scavengers (birds, rodents, and insects). Most landfills stockpile and use soil excavated during construction of landfill cells as a source of daily cover; however, this material is often not sufficient for the life of the landfill cell. Consequently, dirt must be purchased and trucked to the landfill site at considerable expense. In areas where suitable soil is scarce or landfill space is particularly precious, public and private landfill owners and operators have used ADCs since the late 1980s. ADCs include chemical or foam covers, tarps (also referred to a geosynthetic blankets), and other ADCs that make use of selected components of the waste stream itself for cover material.

Using the conventional daily cover of six inches of dirt consumes about 26 percent of a landfill's capacity.[3] In the case of the currently operating landfills in the County, this accounts for 16,949 cubic yards of wasted landfill airspace daily,[4] based on the Draft *Solid Waste Quarterly Disposal Quantity Reporting Summary* prepared by the Los Angeles Department of Public Works for the first quarter of 1995. In-place compacted density of cover soil is roughly 2000 pounds per cubic yard, so the cover materials represent roughly 10,000 tons per day of MSW capacity. This approach may over-calculate cover soil airspace requirements slightly, because of the higher-than-average compaction resulting from the weight of overlying layers of waste in extremely deep canyon landfills.

2. Chemical Or Foam Cover

The cost of foam can be a deterrent, particularly for small landfills. An expanding market, plus vendor competition, is helping to reduce the cost of foam. The City of Glendale, Arizona arranged for their vendor to retain ownership of the application equipment

[3] Darlene Snow, "Alternative Daily Cover Material," *MSW Management*, September/October 1994.

[4] Assumes 38,461 TPD disposed daily at 1,180 pounds per cubic yard.

as well as supplying the product. This strategy means the landfill owner does not have to pay the equipment capital cost up front, and competitive bidding is facilitated because the landfill is not locked in to using only a foam product compatible with purchased equipment. Additionally, foam application is less labor- and time-consuming than using dirt, thus lowering costs. Logan Miller, the Delaware Authority's Facilities Engineer, says, "About 20 minutes before we close, they will go over half the working face with the compactors and dozers and smooth it...Approximately half the working face will be foamed prior to closing...As soon as you're done you turn off the foam supply, and approximately 10 seconds later you turn off the air supply. What happens is that in 10 seconds air is blowing through all the lines, blowing the foam. You shut it down and you go home."[5]

The following foam-type materials have been identified:

- AC-645 Long Duration Foam, manufactured and marketed by Rusmar, Inc., West Chester, Pennsylvania;
- ConCover 180, by New Waste Concepts, Perrysburg, Ohio;
- SaniFoam SDC (synthetic daily cover), by CoverFoam Services, Inc., Florence, SC; and
- TerraFoam ADC and Pneumax Compressed Air Foam Systems, by Chubb Environmental Security, Exton, Pennsylvania.

AC-645

AC-645 is a single component foam composed of non-hazardous and non-toxic anionic surfactants and polymers. The product is supplied in concentrated form, in bulk or 55-gallon fiber drums, and is diluted with water prior to application. Foam is generated using a pneumatic foam unit (PFU). The foam is biodegradable, odorless, and non-reactive, can withstand light to moderate rainfall, presents no fire or explosion hazard, and can be colored to provide low visibility.

[5] Lynn Merrill, "ADC Gets the Dirt Out!" *MSW Management*, September/October 1995.

The viscous foam, which has a consistency of shaving cream, can be applied manually to the working face of small landfills, such as NPLF, with a completely self-contained and portable hand-line foam generating unit. The 800 gallon solution tank of the model 800/40 PFU requires three drums of concentrated AC-645 per filling. The concentrate has no shelf-life restriction and the mixture can be applied in winds under 50 mph, hot or sub-freezing temperatures, although storage should be at non-freezing temperatures. Since the foam product is single component and requires no mixing, there is no need to clean clogged nozzles, hoses and other components.

AC-645 can maintain properties for 36 hours after application. The foam does not harden or dry out, although it will freeze when applied in subfreezing temperatures, and is not intended for vehicular or human traffic after application. However, the foam will not deteriorate overnight, and traffic can operate on the foam the next morning when additional solid waste is disposed. At that time, the additional solid waste will compress the foam without reduction of airspace.

Use of AC-645 foam improves leachate management at landfills, due to reduction of isolated cell formation, and minimizes the potential for perched zone seeps. In addition, infiltration of precipitation is minimized and run-off is promoted if the foam is applied in a thick continuous layer.

Rusmar, Inc., foam products have been used as daily cover at other landfills. AC-645 has been permitted for use at the Lycoming County Landfill, Montgomery, Pennsylvania; Grand Central Sanitation, Inc. Penn Argyl, Pennsylvania; Wayne Township Landfill, McElkattan, Pennsylvania; Delaware Central Solid Waste Facility, Dover, Delaware; Empire Sanitary Landfill, Taylor, Pennsylvania; Keystone Sanitary Landfill, Dunmore, Pennsylvania; Northern Tier Solid Waste Authority Landfill, Blossburg, Pennsylvania; Winnebago County Sanitary Landfill, Lake Mills, Iowa; Cherry Island Landfill, Wilmington, Delaware; Pioneering Crossing Landfill, Birdsboro, Pennsylvania; City of Casper-Balefill, Regional Solid Waste Facility, Casper, Wyoming; and Taziguas Landfill, Santa Barbara County, Goleta, CA. Other facilities are awaiting permit approval.

Disadvantages in use of this foam product include: initial equipment cost is high; specialized personnel training is required; direct contact with skin and eyes should be avoided to prevent irritation; it may be difficult to place in wet weather and high winds; and it cannot be traversed by vehicular traffic.

AC-645 foam costs between $.06 and $.12 per square foot, when applied 3 inches to 6 inches thick, respectively.[6] The trailer mounted 400/25 PFU costs approximately $45,000, and can cover the landfill working face at a rate of 300 to 500 square feet/minute. Larger more expensive units can more than double the rate of coverage.

ConCover 180

ConCover 180 is a "long duration" foam injected, spray applied slurry, usable in both daily and intermediate cover applications. The dry feed material, consisting of an "advanced blend" of "earth-based" components, in a self-setting soluble binder and "recycled material" (wood pulp and shredded newspaper as a bulking agent), is slurried with water in a CAPS-180 (ConCover All Purpose Sprayer-180) and entrained with air (foamed) just prior to application.

Three models/sizes of sprayers are available, each manually operated with either a deck-mounted cannon with 200-foot range or 150-foot self-coiling hose and reel. The CAPS machines also can be used for dust control, power washing, fire fighting and seeding.

ConCover 180 was developed for use in high humidity situations, and can be applied in all climate conditions, including rain and hot or cold temperatures. The "cured" foam sheds water to provide good run-off. The material is environmentally safe, non-toxic and biodegradable; color is either blue or brown. ConCover 180 also can be pH-adjusted to accommodate a variety of water quality.

[6]Personal Communication, Kathy Smith, Rusmar Incorporated (November 30, 1995).

The smallest equipment available to apply ConCover 180 is the CAPS 900-180, a 940-gallon capacity trailer mounted unit, which can apply approximately 7,000 square feet of foam, approximately 1/2-inch thick, in 15 to 20 minutes. Total capacity is 9,000 square feet. Discharge distance is up to 150 feet. The system is reported[7] to cost approximately $35,000, and foam cost is approximately $.08 per square foot (1/2-inch thick).

ConCover 180 has been used as daily cover in a number of landfills. These include: Cumberland County, Fayetteville, North Carolina; Dane County Department of Public Works, Madison, Wisconsin; Wood County Landfill, Bowling Green, Ohio; and Tremont Landfill Company, Springfield, Ohio.

In general, the disadvantages of ConCover 180 are similar to those previously cited for AC-645.

Sanifoam SDC

Sanifoam SDC is a two-liquid component stable aminoplast resin; the two components consist of a foaming agent and a foam stabilizer. The product is diluted with water prior to application and is foamed with compressed air or nitrogen (compressed air normally would be used at a landfill). A pull behind hand-line applicator such as the model PB250-D with two 500-gallon storage tanks would provide 200,000 square feet coverage per application.

The plastic foam, which sets from a fluid to a solid somewhat softer than styrofoam, in 10 to 60 seconds, provides a reflective resilient surface which supports water run-off 15 minutes after application. Maximum water resistance is attained two hours after application. The product is non-toxic and allows plant growth and rooting if part of final cover; also the foam is non-corrosive, contains no irritating, reactive, or pressure generating compounds, and is non-explosive. The foam is non-flammable and self-extinguishing, conforms to OSHA Standards for the workplace, and poses no significant environmental hazard.

[7]Personal Communication, Tim Johnson, New Waste Concepts (November 30, 1995).

SaniFoam SDC can be applied at any ambient temperature, but solutions and material delivery lines must be protected against freezing. It can be applied in moderate winds up to 35 mph (with handheld equipment only) and during light to moderate rainfalls. Once applied and set up, the material can withstand moderate to heavy rain, depending on thickness and method of application. A 1-inch layer of Sani-Foam SDC is claimed to perform equivalent to 6 inches of compacted soil.

The unmixed SaniFoam stabilizer has a shelf-life of approximately 90 days and should be stored in a heated area during cold weather; the foaming agent has no shelf-life restriction. The nozzle used to spray the foam must be cleaned after each use, and equipment flushed with hot water; a hot water flush/rinse down system is a component of the application equipment. Mixing of SaniFoam components and equipment flushing are performed automatically by the equipment.

SaniFoam SDC has been tested and used at several landfill sites, including: the City of Arlington, Texas; City of Corpus Christy, Texas; Outagamie Solid Waste Authority, Appleton, Wisconsin; CDT Landfill, Inc., Joliet, Illinois; Waste Management of Pennsylvania, Inc., Morrisville, Pennsylvania; Peoria Disposal Company, Peoria, Illinois; E.I. Dupont Facility, Victoria, Texas; and U.S. Army Munitions Plant, Texarkana, Texas.

Similar to other foam products, cost of application equipment is high; minimum cost for the PB250-D Spray Bar applicator is approximately $105,000. However, these units will be provided for free by CoverFoam Services, Inc. if the customer commits to long-term use of the foam product. SaniFoam SDC foam costs approximately $.08 per square foot.[8]

TerraFoam

TerraFoam is a natural, biodegradable protein-based material that stays moist after application. Two TerraFoam products are available. The low expansion product lasts 72 hours

[8]Personal Communication, Ernie Straus, CoverFoam Services, Inc. (November 30, 1995).

or longer when left undisturbed. It is wind- and rain-resistant, inhibits fire from starting or spreading, and can be applied to a landfill surface by Pneumax skid units, custom-designed, foam application vehicles operated by one person. Terrafoam can also be applied using a Pneumax Spray Bar unit for larger applications. A higher expansion TerraFoam product, which is produced with additional air-entrainment, can resist wind and light rain for more than 24 hours. Both products are recommended for six-inch thick application.

TerraFoam is environmentally safe and, after application, begins to degrade through evaporation with total effectiveness depending on climate conditions. The product compresses under solid waste disposed the next working day, thus extending landfill life beyond that filled with soil cover.

Currently, TerraFoam is being used at several landfills in California, including: High Grove Landfill, Riverside; San Marcos Landfill, San Diego County; and Ojai Landfill, San Diego County.

Several sizes of delivery equipment are manufactured: a tractor mounted system for large landfills, skid mounted on truck body, and a small trailer mounted unit. The trailer mounted unit can be served by water truck, is simple, requires little clean-up time and components need not be pre-mixed.

The average cost of a 4 to 6-inch thick blanket of TerraFoam is approximately $.10 per square foot. The cost of the small trailer mounted TerraMAC unit is approximately $30,000; application rate is about 250 square feet per minute (5,000 square feet in 20 minutes).

2. Tarp Cover

Tarps or geosynthetic materials are another form of alternative daily cover that can provide dramatic savings in landfill airspace. Although tarps cost considerably more per square foot than dirt, they are cost-efficient due to their reusability.

The following geosynthetic materials have been identified:

- Airspace Saver, manufactured and marketed by Wire Rope Specialists, Baton Rouge, Louisiana;
- Aqua-Shed, by Aqua-Shed Manufacturing Corporation, Florence, South Carolina;
- Covertech C-440, manufactured by Fabrene Inc., Mississauga, Ontario, Canada, and marketed by Covertech Fabricating, Inc., Etobicoke, Ontario, Canada;
- Daily Landfill Covers manufactured by Belton Industries, Inc., Atlanta, Georgia, and marketed by Pallen Enterprises, Inc., Conyers, Georgia;
- Fabrisoil, by Phillips Fibers Corporation, Greenville, South Carolina;
- GeoCover 601, by New Waste Concepts, Perrysburg, Ohio;
- Permalon X-150, by Reef Industries, Houston, Texas;
- Sani-Cover, manufactured by Amoco Fabrics & Fiber Co., Atlanta, Georgia (series 100 and 200) and Hoechst Celanese Corporation, Spartanburg, South Carolina (Series 300), and marketed by Fluid Systems, Inc., Cincinnati, Ohio; and
- Typar DLC (daily landfill cover), manufactured by Reemay, Inc., Old Hickory, Tennessee, and marketed by Exxon Chemical, Summerville, South Carolina.

Geosynthetic products used for ADCs generally are distributed as sheets or panels in rolls or pallets (accordion pleated and rolled or folded). The panels are placed manually or with use of wheeled or track-type vehicles. After application and overlapping, these materials generally are prevented from blowing loose using tires or sandbags as weights. Concrete blocks also are used, but may damage the product if not used with care. Prior to deposition of solid waste during the next working day, the panels are removed and stored for reuse near the working face.

Most geosynthetic products either are woven, nonwoven or are produced as a film. Films resist water and landfill gas penetration whereas the other products generally will allow some gas and water to penetrate to some degree, depending on pore size. This can provide problems in application or roll-back when water increases weight during rainy weather or when water in pores freezes during cold weather use. Geosynthetic products generally are inert, non-reactive,

lightweight, strong, reusable, and flame resistant.

Final cost of a geosynthetic panel is determined by the number of times it can be reapplied (recycled). After final use, the panel can be discarded in the landfill.

Airspace Saver

Airspace Saver is a woven polyethylene fabric, coated on both sides with additional polyethylene to render it water resistant.[9] Maximum standard panel size is 48 x 50 feet; multiple panels can be overlapped to cover a larger area. The manufacturer also can custom fabricate larger pieces by heat welding 12-foot wide panels.

The product is supplied accordion pleated and rolled. Nylon web straps are spaced 12 feet apart and secured to the panels either in one direction or two directions in a checkerboard pattern across the panels. D-rings are attached to the ends of the web steps for ease of installation. The manufacturer will optionally sew a 3/8-inch chain or wire rope into the perimeter of finished panels to aid security in windy weather.

Two products are available. Product TJBX is a 7.2 mil thick fabric weighing approximately 5 oz. per square yard. Cost is $.25 per square foot; rated life is 6 to 10 months, depending on how the material is handled. Product TGNN is 17.2 mils thick, weighing 9.6 oz. per square yard. Cost is $.40 per square foot, with life rated at 1 to 1 1/2 years (some products have displayed a life of approximately 2 years). Cost of chain or wire rope around the perimeter of the finished panel is approximately $2 per linear foot.

Airspace Saver is used in a number of landfills as daily cover. These landfills include, for instance: City of Lynchburg, City Landfill, Lynchburg, Virginia; Chesterfield County, Virginia; and Lunenburg County Landfill, Lunenburg, Virginia. Product TGNN is used at each of these landfills.

[9]Personal Communication, Marion Yarborough, Wire Rope Specialists (May 6, 1993).

The following Waste Management, Inc. landfills use Airspace Saver daily cover: Skyline Landfill, Ferris, Texas; Gulf Coast Landfill, Ft. Meyers, Florida; Hickory Hill Landfill, Ridgeland, South Carolina; Piedmont Landfill, Kernersville, North Carolina; Brushy Hill Landfill, Little Rock, Arkansas; East Oak Landfill, Oklahoma City, Oklahoma; Central Disposal, Pompano, Florida; Plantation Landfill, Sibley, Mississippi; Quarry Landfill, Tulsa, Oklahoma; and Westside Landfill, Aledo, Texas. Airspace Saver also is used at Thurston County Public Works, Hawk Prairie Landfill, Olympia, Washington; and Winnebago Reclamation, Rockford, Illinois.

Aqua-Shed

Aqua-Shed is a lightweight, reusable, tan colored PVC sheet. For long-term use, as intermediate cover, the sheets are coated on one side with a polybutene aqueous emulsion glue for adherence to the landfill surface. The sheets are 6 mils in thickness and supplied in palletized cardboard boxes in sizes from 168 square feet (28 x 6 feet) to 4800 square feet (100 x 48 feet); this sheet thickness may make installation difficult on windy days. Weight of an Aqua-Shed panel is approximately 50 pounds per 1,000 square feet. Panels soon will be available in rolls.

The panels are not combustible (self-extinguishing) and can elongate 300 percent before breaking; the material is easy to patch. Installation can be accomplished by two persons without mechanical equipment.

Aqua-Shed has been used as daily and intermediate cover on the Kona Municipal Landfill, Hilo, Hawaii. It is reported that Aqua-Shed has reduced incidences of fires at the landfill.[10] The product also has been used at the Bath Landfill, Bath, Maine, where it is noted that the panels could not be punctured with the operator's steel-wheeled compactor.[11]

[10]Department of Public Works, Hilo, Hawaii. Letter signed by Galan M. Kuba, P.E., Solid Waste Division (April 7, 1992).

[11]Kimball Chase Company, Inc., Bath, Maine. Letter signed by Stephen C. DeWick, P.E., Vice President (April 14, 1992).

Cost of Aqua-Shed (unglued) is $.10 per square foot, F.O.B. Florence, South Carolina. Aqua-shed cover is reported to last 90 to 700 days, depending on how it is handled.

Covertech C-440

Covertech C-440 is a clear or pigmented (colored) woven polyolefin fabric.[12] The material is made of high density polyethylene tapes coated on both sides with low density polyethylene. Reinforced web straps support the material on both sides every 12 feet in both directions, with straps extending over the hem with a D-ring. This design allows for easy installation over compacted solid waste using existing equipment or manpower. None of the woven polyolefins are considered hazardous under normal conditions. The material is stable, chemically inert, and does not present a health hazard.

Due to the fabric's high slip factor (compared to non-woven materials) the cover can be dragged easily on and off solid waste. If the area to be covered is small (e.g., 48 x 50 feet), two to four persons can easily drag it over the working face. The material is secured with tires or sandbags; however, the manufacturer will include an optional chain in the hem for added weight around the perimeter.

Life expectancy of Covertech C-440 is between 10 and 18 months, depending on use. Cost is $.40 per square foot, and it is supplied with one dimension in multiples of 12 feet, up to 72 feet (stock size is 48 x 50 feet).

Covertech C-440 has been used at a number of landfills: Pottstown Landfill (Waste Management of PA, Inc.), Pottstown, Pennsylvania; Kankakee Recycling & Disposal Facility (Waste Management of Illinois, Inc.), Kankakee, Illinois; B.F.I. Charlotte Motor Speedway Landfill, Charlotte, North Carolina; B.F.I. Samson County Landfill (Roseborough, North Carolina); B.F.I. Muskigum Landfill (Zanesville, Ohio); and others.

[12]This product is identical to Airspace Saver.

Daily Landfill Covers

Daily Landfill Covers are fabricated to specific requirements from wide width panels of woven polypropylene. A wide-range of fabric weights (ranging from 3.8 to 8 oz./square yard), strengths and blanket configurations are offered. The basic cover can be manufactured with pockets on each corner to facilitate ease of movement in all directions either manually or with machinery.

The material generally is available in 12.5 foot or 15 foot widths which can be fabricated, double-stitched, into covers up to 75 feet wide and any desired length. Rolls come on 4-inch diameter heavy duty corrugated cores.

Panels are either black, grey, or white in color, and also can be supplied with straps and D-rings at corners. Of six styles offered,[13] styles 796 and 113 generally are used by landfill operators. Style 796 is a 5.4 oz. per square yard black fabric costing $.20 to $.22 per square foot, depending on size. Style 113 costs $.30 to $.32 per square foot and weight 8 oz./square yard. Cost includes web straps and D-rings.[14]

Daily Landfill Covers are used at a number of landfills. Style 796 is used at the Hall County, Georgia, Landfill and City of Macon, Georgia, Landfill. Style 113 is used in 75 x 100-foot panels at BFI and Chambers Development Company landfills, and others. These include, for instance: Roberts Road Landfill, Fayetteville, Georgia (BFI); Oak Ridge Landfill, Dorchester, South Carolina (Chambers) and Chambers Atlanta Landfill, Georgia.

Fabrisoil

Fabrisoil reusable ADCM is a nonwoven, needlepunched polypropylene fabric which is heat set on both surfaces. The staple fiber, needlepunched, heat set construction provides a 3-

[13]Styles 768, 507, 776, 777, 796 and 113.

[14]Personal Communication, Gregory T. Pallen, Pallen Enterprises (May 6, 1993).

dimensional structure which resists snagging on solid waste, and will not de-laminate on reuse.

Generally, a Fabrisoil panel can be used as long as two weeks or more. The panels are shipped folded accordion-style, then rolled up.

Fabrisoil is strong enough to be pulled into place with existing equipment, and if the area is small (say 30 x 50 feet), two persons can easily install. Edges are secured every 20 feet with tires or sandbags. If it is windy, more anchoring may be required. Typically a 100 x 100-foot area can be covered in 10 to 15 minutes. This represents a reduction in time of installation of 85 percent compared to installation using soil as daily cover.

Fabrisoil has been used on more than 20 landfills. At the Rowan County Landfill, Salisbury, North Carolina, the average working face is 100 x 100 feet. At the McLean County Landfill, Bloomington, Illinois (owner-operator John Sexton Contractors Company), life of the Fabrisoil is 15 to 20 uses, saving about 167 cubic yards of airspace per day (daily working face measure 90 x 100 feet).

Fabrisoil costs about $2 per square yard (approximately $.22 per square foot).

GeoCover 601

GeoCover 601 is a nonwoven geosynthetic polypropylene fabric. Each GeoCover 601 panel is custom made specifically for the customer and is delivered to the landfill site ready to use. The manufacturer suggests that panels be no wider than 80 feet. The cover is lightweight (6 oz. per square yard) and has a very low moisture absorption rate, making it easy to handle. The panels are constructed with webbing sewn around the perimeter and with handles every 20 feet.

The product is rolled or dragged, either manually or with on-site landfill equipment, across the surface of the landfill; life of the material depends on how it is handled. For instance, use in Wayne, Michigan, has displayed a life of approximately 30 days. At a site in

Minnesota, a 6-month life was observed.

The product is "certified" for use at landfills in 15 states.[15] Cost is $1.20 per square yard.

Permalon X-150

Permalon X-150 is described as an "alloyed high-density, PE membrane." The product is manufactured with 12 layers of polyethylene oriented in the machine direction, the transverse direction and at 45 degree angles to both directions. Stock size sheets are available up to 100 x 100 feet, constructed of 4-foot wide heat-seamed panels; larger sheets are available up to 200 x 200 feet. All covers can be custom fabricated with grommets, pipeloops, etc. . Thickness of Permalon X-150 is 8.6 mils, with a weight of 30.4 lb per 1,000 square feet.

The product is watertight, but currently is not fire retardant.[16] Cost of Permalon X-150 is $.10 to $.14 per square foot depending on quantity ordered. Currently, the manufacturer is testing an improved product, with geotextile backing (6 oz. nonwoven). Cost is projected to be $.18 to $.20 per square foot.

Permalon X-150 is used at the North Western Landfill (Mid-American Waste Systems), Parkersburg, West Virginia, and the County Environmental Landfill (Envirite Corporation), Pontiac, Illinois.[17]

Sani-Cover

Sani-Cover is available in woven polypropylene (Series 200), non-woven needlepunched polypropylene (Series 100), and non-woven needlepunched "Trevira" 100 percent continuous

[15]Personal Communication, Berthold Rossnagel, New Waste Concepts (May 4, 1993).

[16]Personal Communication, Lynn Ciolli, Reef Industries (May 6, 1993).

[17]Personal Communication, Ralph Jelic, R.A. Jelic Company (May 7, 1993).

filament polyester fabric (Series 300), to serve various field conditions. Non-woven polypropylene and polyester panels provide higher elongation characteristics which reduce the possibility of sharp or pointed objects tearing or puncturing Sani-Cover during deployment. Woven polypropylene, on the other hand, displays water repellency for use in rainy climates.

Sani-Cover is designed for quick and easy deployment using minimal time and labor. For instance, bars can be inserted into pockets sewn into the finished panel for ease in pulling across the landfill working face. The product either can be installed using on-site landfill equipment or it can be deployed manually.

A standard size panel, approximately 100 x 100 feet, can be installed by three persons in approximately 10 minutes.[18] Panels can achieve a lifecycle of more than 60 days use. The cost of Sani-Cover is $.15 per square foot, F.O.B. plant at Dallas, South Carolina.

Sani-Cover is being used at more than 100 landfill sites around the country. On the east coast, these sites include: City of Waco, South Carolina; City of Greensboro, North Carolina; Caldwell County (Hudson, North Carolina); Southern Solid Waste Management Center, Georgetown, Delaware; and Millersville Landfill, Anne Arundel County, Maryland.

At the Millersville Landfill, two Series 200 panels, each measuring 150 x 150 feet, were purchased at a cost of $6,000. The first panels was replaced after seven weeks use. As of May 1993, the second panel had been in use three weeks. Material from the first panel currently is being used to line stormwater diversion ditches and other structures, thereby extending the useful life. Landfill personnel at Millersville are satisfied with Sani-Cover.[19]

[18]Personal Communication, David Powell, Fluid Systems (May 5, 1993).

[19]Personal Communication, Dub Deeson, Millersville Landfill, Anne Arundel County, Maryland (May 27, 1993).

Typar DLC

Typar DLC is made from thermally-spunbonded (non-needlepunched) polypropylene fibers.[20] Standard size fabric panels, in stock, measure 46 x 100 feet; however, the manufacturer can fabricate custom-made panels in any size. Panels are shipped accordion-folded and rolled for ease of application. Depending on how panels are handled, use can extend for at least a year (the vendor advertises a 6-month life). Panels do not snag; however, if necessary, they can be repaired easily.

Although the product is permeable, Typar-DLC tends to shed water. In addition, the product does not take on water or excess soil during use, which would increase weight and cause problems in handling.

Typar DLC can be installed using existing machinery or can be handled manually. A 46 x 100 foot panel weighs approximately 200 pounds (about 6.25 oz. per square yard and can be deployed in 10 or 15 minutes by three people). Cost is $530 (about $0.11.5 per square foot).

Among others, Typar Daily Landfill Cover is being used at the Pekin Metro Landfill, Pekin, Illinois; Clinton Landfill, Clinton, Illinois, and Taswell County Landfill (Waste Management of Illinois), East Peoria, Illinois, where service life of panels has exceeded six months.

3. Other ADC Technologies

Alternative daily covers used by some communities make use of materials that would otherwise be part of the waste stream. An example is the fine material generated by Construction and Demolition debris (C&D waste) processing that consists primarily of soil and shredded wood utilized by Waste Management at the Collier County Landfill in Florida. C&D processing now diverts much of the C&D material from disposal, and the fines ADC, which

[20]Personal Communication, Tom Miller, Exxon Chemical (May 7, 1993).

would have been landfilled in the past, now saves the operator $250,000 per year that would have been spent on cover dirt.[21]

Another ADC that is familiar to Los Angeles County is the use of ground green wastes. The Los Angeles Sanitation Districts estimate that up to 600,000 tons (roughly half) of the green wastes could be used as ADC per year. However, because of opposition by the Natural Resources Defense Council (NRDC), the CIWMB may change its policy of counting the use of green wastes used as ADC toward achieving the County diversion goal. The CIWMB considered the problem, and recently confirmed its decision to accept green waste ADC as diversion until such time that adequate markets for green waste compost and mulch develop.

Finally, several commercial slurry products make use of recycycled materials. The following slurry-type materials have been identified:

- ConCover, manufactured and marketed by New Waste Concepts, Perrysburg, Ohio; and
- Posi-Shell, by Landfill Service Corporation, Apalachin, New York.

ConCover

ConCover is an ADCM engineered for use as a daily landfill cover with a life expectancy of 1 to 10 days. The "earth based" polymer spray-applied slurry is composed of two components: a fiber matrix and polymer binding agent. The fiber matrix (bulking agent) is prepared with recycled shredded newspapers and wood pulp.

ConCover can be mixed and applied with the same equipment used to apply ConCover 180, described earlier in this Appendix (see Foam Products). Complete coverage can be attained with a 1/4-inch thick layer, which provides protection equivalent to 6 inches of soil. In approximately 60 minutes, the cover will resist climate conditions; prior to that time, the product

[21] Lynn Merrill, "ADC Gets the Dirt Out!," *MSW Management*, September/October 1995.

is subject to deterioration if an extreme rainfall takes place. ConCover performs best in lower humidity conditions.

At the landfill in Wood County, Ohio, ConCover replaces approximately 150 cubic yards of daily soil cover, saving approximately 43,000 cubic yards of air space annually.[22] Each morning, the mobile spray equipment is filled with 200 gallons of water, to be used for dust control and on-site fires, if necessary. At the end of the day, landfill personnel add bags of ConCover (and an additive, if it is raining). The mixed slurry is then applied over the 150 x 40 foot working face in about 15 minutes, forming a crust in 30 minutes to 1 hour.

ConCover also is used at two landfills in the State of Iowa. These include the Linn County Landfill, which serves the area around Cedar Rapids, and the Webster County Landfill, which services the area around Ft. Dodge.

The cost of ConCover is $.07 per square foot, with equipment cost the same as cited with ConCover 180.

Posi-Shell

Posi-Shell is an environmentally compatible combination of: a filler consisting of a mixture of solids containing 100 percent recycled cellulose fibers and plastics; and a recycled alkaline mineral binder liquid; which is formulated to be mixed either with water or landfill leachate, and sprayed onto the landfill surface. The mineral binder component acts to neutralize odors and contaminants present in landfill leachate. After application, the Posi-Shell slurry hardens to an earth-tone, non-flammable coating.

A horizontal mobile silo is used to store and dispense the binder and a mobile Posi-Shell Applicator mixes ingredients supplied in Posi-Pak bags, and maintains the slurry in constant agitation prior to application. Larger landfills may require multiple set-ups. The mobile

[22]Landfill Uses Old Newspapers as Daily Cover Materials. Pollution Engineering, pp. 122-123 (September 1991).

The increased moisture content from recirculating leachate promotes biological activity, resulting in faster decomposition of organic materials and a concomitant increase in the rate of landfill gas production. The more rapid loss of solids from decomposition in the landfill speeds the consolidation of the landfilled material and the resultant settling.

Laboratory studies of leachate recirculation have shown that decomposition periods can be reduced to 18 to 36 months, as opposed to the 20- to 30-year period normally associated with refuse decomposition.[24] Although these studies are done on small-scale models and field tests do not reveal such dramatic increases in stabilization rates, leachate recirculation has proven to have a considerable effect on waste decomposition in landfills. At the Alachua County Southwest Landfill in Florida, it was assessed that in cells with leachate recirculation, the half-life of the waste's biodegradable mass was decreased to 3 to 5 years; this compares to a half-life of 10 or more years for the waste in untreated sections of the landfill.[25]

2. Biostabilization

An evolving concept of landfilling, stabilized placement or biostabilization, is gaining significant interest as a means to substantially conserve landfill space, particularly where disposal capacity is at a premium and conservation of natural soils is important. In the biostabilization process, following the removal of recyclables, solid waste to be landfilled is shredded and the moisture content is adjusted (preferably to between 40 and 60 percent). The shredded waste is then aerated for a period of 60 to 90 days. Following the aeration period, the waste is compacted with standard landfill compaction equipment. Experience at an operating facility in Albany, New York indicates that after biostabilization, 50 to 100 percent more refuse can be placed in the landfill cell when compared with conventional landfilling.[26]

[24]Kevin O'Leary, "Development of Leachate Disposal Processes," *Waste Age*, July 1995.

[25]T. Townsend, W. Miller, R. Bishop, and J. Carter, "Combining Systems for Leachate Recirculation and Landfill Gas Collection," *Solid Waste Technologies*, July/August 1994.

[26]David L. Hansen, "Biostabilization of Landfill Waste," *Waste Age*, June 1995.

3. Baling

Baling solid waste prior to landfill disposal is another technique that has proven to conserve landfill space. By operating the landfill as a balefill, on average, 45 percent greater compaction will be achieved when compared with conventional compaction methods. Typical bales (3' x 5' x 4') of MSW weigh up to 3,000 pounds, and a well-designed and operated balefill may consume less than half of the equivalent active fill or cell area as a conventional landfill operation for the same tonnage of waste and the same height of fill.

At the Jonesboro Landfill in Craighead County, Arkansas, an initial density of 1,500 pounds per cubic yard is achieved by feeding the waste through a baler prior to disposal (a 25 percent increase over the density estimated for Elsmere).

4. Landfill Reclamation (Mining)

Landfill reclamation, or landfill mining, is the excavation and mechanical processing of previously landfilled material to recover materials or landfill airspace, reduce the size of the landfill, or transfer material from an unlined to a lined landfill.

An extensive evaluation of a landfill mining site was performed in Collier County, Florida by the U.S. EPA's Risk Reduction Engineering Laboratory. During a two-week demonstration period in 1992, County staff mechanically processed 292 tons of excavated material through coarse and fine screens, an air knife/de-stoner, and magnetic separators into nine fractions. Two of these fractions -- a soil fraction and a ferrous metal fraction -- were determined to be reusable. The recovery of ferrous metals averaged about 75 percent with a purity of 82 percent.[27]

A reclamation project at the Frey Farm Landfill, in Lancaster, Pennsylvania, involves continual hauling of the excavated waste to a neighboring WTE facility. The Lancaster County

[27]John T. Aquino, "Reclaiming Landfills: Amazing Interest," *Waste Age*, February, 1994.

Solid Waste Management Authority (LCSWMA) reports that revenues from the sale of electricity and recovered ferrous metal offset operating costs of the landfill reclamation project and result in net revenues of $3.94 for every ton of reclaimed refuse delivered to the WTE facility. Additionally, the mining operations are creating 2,500 cubic yards of vacant landfill space each week.[28]

APPENDIX D

APPENDIX D: SEATTLE, WASHINGTON CASE STUDY

A. INTRODUCTION

The successful recycling program in the City of Seattle, Washington proves that diversion rates of 50 percent and beyond are realistic and obtainable. The latest recycling program studies reveal that Seattle experienced a 48.2 percent recovery rate in 1993. Given that Seattle's diversion rate has leaped from 22.0 percent in 1985, to 40.0 percent in 1990, to 48.2 percent in 1993, it can be inferred that the current recycling rate is well over 50 percent.[1] The following is a summary of the management and success of Seattle's waste and recyclables collection system.

B. BACKGROUND AND LEGISLATIVE FRAMEWORK

Seattle's Solid Waste Utility was established in 1961 to manage collection and disposal of waste in the City of Seattle. It is a public Utility of the City of Seattle and a division of the City's Engineering Department. The Utility, which was established as an Enterprise Fund, is self-supporting, primarily by user fees, and receives no subsidies from the City's General Fund.

The Utility functions both in an administrative role and as a direct-service provider. It contracts with private companies for residential waste and residential recyclables collection and processing services; develops overall policies that affect private collection of commercial waste; and contracts for solid waste transport and disposal, as well as certain household hazardous waste transport and disposal services. It also owns and operates transfer stations and a permanent household hazardous waste drop-off facility.

Resolution 25872, adopted by Seattle's City Council on August 14, 1978, called for establishment of recycling goals, and stressed the importance of market stability, source separation, and support for the existing recycling organizations. Recycling targets in the City

[1] "City of Seattle November/December Curbside Recycling Report," City of Seattle, February 1995.

have been steadily increasing since the late 1970s. In 1988, the City Council adopted Resolution 27871 establishing the solid waste management policies that are the basis for Seattle's Integrated Solid Waste Management Plan (the Plan). The Plan is adopted by the City under the authority of the Revised Code of Washington, 70.95.080 (1), which allows the City to "prepare and deliver to the County auditor of the County in which it is located, its plan for its own solid waste management for integration into the comprehensive County plan."

The Plan sets waste reduction and recycling goals of 40 percent by 1991, 50 percent by 1993, and 60 percent by 1998, and it directs the Utility to implement the waste reduction, recycling, composting, and disposal programs necessary to achieve these goals. Resolution 27871 also mandates a schedule for implementation of these programs and expresses the intent of the City of Seattle to manage the disposal of its residential and commercial solid waste independent of King County.

C. COLLECTION AND TRANSFER SYSTEM

1. Residential Collection

The City contracts with two local companies, U.S. Disposal (owned by Rabanco, Inc.) and General Disposal (owned by Waste Management, Inc.), for mandatory, weekly residential waste collection (including single-family households and multi-family properties of up to four units) in three areas of the City. The contractors serve approximately 250,000 households. Customers are offered a choice between curb/alley and backyard collection, with a 40-percent rate discount incentive for choosing curb/alley collection. For curb/alley customers, contractors supply containers sized according to the customer's chosen level of service, ranging from a mini-can (19 gallons) to a 90-gallon cart. A pre-paid trash sticker is also available for excess waste.

Waste generated by Seattle households and collected by the two City contractors is hauled to one of two City-owned transfer stations. The waste is then transferred to City trucks and hauled by the City to the rail yard transfer station. It is then rail-hauled to Columbia Ridge

Landfill in Arlington, Oregon, which is owned and operated by Washington Waste Systems, a subsidiary of Waste Management, Inc.

In 1988, the City began offering curbside collection of recyclables to residents. Curbside recycling services are offered on a voluntary, subscription basis to 148,500 single-family households and multi-family units (up to four-plexes) by two local hauling companies: Recycle America and Recycle Seattle. The North-side contractor, Recycle America (a Waste Management Company), provides weekly pick-up of recyclables in three, 15-gallon stacking bins -- one for newspaper, one for mixed paper (all forms of residentially-generated paper, e.g., newspaper, magazines, junk mail, cereal boxes, and corrugated cardboard), and one for glass, plastic (PETE and HDPE), and metal (tin, aluminum, and bimetal) containers. The South-side contractor, Recycle Seattle (a Rabanco Company), provides monthly pick-up of the same materials in 60- or 90-gallon wheeled toters. To alleviate some of the glass breakage occurring during commingled collection of the materials, Recycle Seattle has provided customers with a small container for glass storage that hooks onto the outside of each toter.

The City also provides contracted curbside collection of yard trimmings. Curbside yard trimming collection service is provided by two companies: (1) General Disposal Corporation provides weekly pickup year-round; and (2) U.S. Disposal Service provides bi-weekly pick-up from March through October, and monthly pick-up from November through February. Yard trimmings are also accepted from businesses and residents at the two City transfer stations. All yard trimmings collected in the City are then hauled to Rabanco's Cedar Grove Compost Facility for processing. The City also operates an education program to encourage backyard composting.

Except for yard trimmings, there is no additional charge for curbside recycling services. Residents are charged monthly for yard trimming collection; the cost of collecting other recyclables is included in the residential fee structure. A multi-family recycling program targeted at multi-family residences with more than four units began in 1993.

In addition to the City's curbside recycling program, the two City transfer stations provide drop boxes for all materials accepted at the curb, as well as vehicle batteries, motor oil,

oil filter containers, mattresses, "sharps" (i.e., needles), ferrous and non-ferrous scrap metal, and used lumber and wood. Residents can drop off these materials free of charge. White goods and used automobile tires are accepted for a charge.

The Utility participates in the Regional Household Hazardous Waste Program and has owned and operated a permanent household hazardous waste facility (located next to the South Transfer Station) since 1988. The facility is open to both City and County residents.

2. Commercial Collection

Commercial solid waste collection in Seattle is regulated by the Washington Utilities and Transportation Commission (WUTC). Although the City has the authority to contract for commercial waste collection, and may do so in the future, Seattle's businesses and industries are served by four collection companies holding certificates from the WUTC. The City monitors WUTC decisions and, through the Plan, establishes recycling service levels, rate structure requirements, and data-reporting requirements necessary to meet the City's recycling goals. Although the City does not set rates for commercial collection, it participates in WUTC rate hearings to ensure a rate structure that encourages waste reduction and recycling in accordance with the Plan.

3. Government/Institutional Sector Collection

City government buildings are considered a residential customer; they use dumpsters and receive waste-collection services from Rabanco and Waste Management. Other government buildings and most City institutions contract for waste collection with private haulers.

4. Transfer Stations

There are four transfer stations located in Seattle where collection vehicles transfer waste to larger transfer trailers (rail cars) for long-haul to the Columbia Ridge Landfill in Arlington, Oregon. Two of the transfer stations are owned and operated by the City within the Enterprise Fund. Generally, the two City-operated transfer stations serve the self-haul customers and the residential collection contractors hired by the City.

The two private transfer stations are owned and operated by two private companies that collect waste from commercial accounts in Seattle and outside of the City. One such facility, owned by Rabanco, receives, processes, and transfers many different types of materials, including recyclables from the residential curbside recycling contract, commercial paper loads, construction and demolition debris, and commercial MSW. The Eastmont Development Transfer Station, owned and operated by Waste Management, receives waste from Bayside Disposal and other collection firms operated by Waste Management in the Seattle area. Waste from commercial and industrial accounts inside and outside of the City and residential waste from outside of Seattle are delivered to the Eastmont Development site.

D. VARIABLE RATES

The City Utility has instituted a weight-based rate system, which is calculated by the size of the container provided to each generator. As shown in Table A-1, rates range from a 12-gallon "Micro Can" at $9.37 per month up to a 90-gallon cart at $44.94 per month for curbside collection. The Utility has experimented with on-board weighing systems to provide more accurate weight-based fees, but has not implemented a full-scale program.

Collection service also provides, for the larger can sizes, the option of backyard (rather than curbside/alley) service for an additional cost. Note that there are no charges for recyclables collection, and the $3.00/month rate for yard waste collection is set low enough to encourage resident diversion.

Table D-1. City of Seattle, Washington Rates

Residential Monthly Rates of Containers

	Weight Limits	Curb/alley	Backyard
Micro Can (12 gal)	- 20 lbs.	$ 9.37	not available
Mini Can (19 gal)	- 30 lbs.	$11.50	not available
32 Gallon Can	- 60 lbs.	$14.98	$20.96
60 Gallon Cart or (2 32-gal)	- 120 lbs.	$29.96	$41.94
90 Gallon Cart or (2 32-gal)	- 180 lbs.	$44.94	$62.92
Yardwaste 5 units/week	- 60 lbs.	$ 3.00	not available

Disposal Stations Fees and Charges
(Reyclables can be dropped off free of charge)

	White Goods (large appl.)	Garbage, Tires and Mattresses	Clean Yard Waste Clean Wood Waste
Passenger vehicle	$14.00/item	$ 7.00/trip --	$ 6.00/trip
Non-passenger vehicle	$14.00/item	$83.00/ton	$64.00/ton
Minimum disposal fee			
Non-passenger vehicle	$14.00/item	$13.50/trip	$10.00/trip

"Clean" means a load is entirely yard waste or entirely wood waste. Mixed loads will be charged the garbage rate. If you bring yard waste and garbage in the same vehicle, you pay the rate for garbage.

Yard waste and garbage must be separated prior to disposal.

If you bring appliances and garbage in the same vehicle, you pay the rate for garbage plus $5 per appliance.

Source: *The Economics of Recycling and Solid Waste Management for the 90s*, Harvey Gershman, GBB, Municipal Waste Management Association, March 24, 1994.

Similarly, there is no fee for recyclables drop-off at Disposal Stations, where residents can bring bulk wastes.

E. RECYCLABLES DIVERSION

The key to the success of the City of Seattle's recycling program is the participation rate among eligible households. As of December, 1994, 91.1 percent of the 149,500 eligible households are participating in the City recycling program. On the North Side of the City, 98.9 percent of the households participate. In addition, Seattle averages five new sign-ups per day.[2]

The latest quantitative analysis of the recycling program, which is for the year 1993, revealed that the City of Seattle experienced a 48.2 percent diversion rate. The breakdown of generation and diversion rates for each waste component is included as Table A-2.

In 1985, 22.0 percent of the waste in Seattle was being recovered, and in 1990, a 40.0 percent diversion was experienced. Given the 1993 diversion rate of 48.2 percent, and recognizing the upward trend in recycling recovery rates, it seems Seattle is on target to reach the 1998 goal of 60 percent diversion.

[2] "City of Seattle November/December Curbside Recycling Report," City of Seattle, February 1995.

APPENDIX E

APPENDIX E: ENTERPRISE FUNDS AND FULL COST ACCOUNTING

This Appendix discusses some of the cost issues relevant to integrated solid waste management planning. It is not possible to develop a detailed cost plan for the recommendations made in the report. To do so would require obtaining present cost data from the County and the County Sanitation Districts of Los Angeles County, as well as from each of the Cities in the County.

Determining the actual cost of solid waste management is one of the most difficult tasks encountered by communities developing integrated solid waste management plans. Many costs, particularly overhead costs such as personnel management, are handled by separate departments. The amount of time allocated to management of solid waste personnel must be estimated as part of the overall cost of solid waste. In addition, divisions often share equipment, marshalling yards or supervisory personnel, or pitch in together to provide emergency services, making it difficult to identify solid waste-specific costs.

The objective in this Appendix is to get the County thinking about how to develop a coherent integrated solid waste management system and help communities control costs. The County can function in a key coordinating role. This does not mean that the County shoulders all costs or manages all facilities; it means that the County actively supports the Cities and facilitates their operations. Elaborate solid waste systems can be very costly if program components are added piecemeal. County leadership can be critical in this area through:

- preparing the County Comprehensive Plan to coordinate efforts between the various County jurisdictions or provides joint City/County-sponsored facilities;
- developing facilities that serve multiple jurisdictions (e.g., transfer stations) that, through economies of scale, keep costs down despite possible longer haul distances;
- developing County model programs, including a variable rate fee system for County-collected areas and technology demonstration programs for landfill operations (see Chapter IX.F); and
- maintaining the economic viability of existing facilities, for example, through waste transfer to the WTE facilities (Chapter IX.H) or developing a policy of purchasing

supplies from recycling enterprises ("Buy Recycled") that utilize recyclables collected in Los Angeles County.

In addition to the coordinating role, the County can pioneer some innovative ways of financing solid waste management programs that also foster diversion of waste from disposal, including: enterprise fund accounting, and variable rate fees ("unit pricing"). Also discussed in this Appendix are the relative share of the solid waste dollar cost for different system components, and factors influencing costs. These two topics provide background for Report discussions.

A. ENTERPRISE FUNDS

Operating an integrated solid waste management system as an enterprise fund allows communities to track the true cost of service, and keeps the funding for services separate from the political vagaries of the government budgeting process. In an enterprise fund, all revenues and costs go to a cost center. Revenues do not go to the General Fund, debt service is not paid for by Finance, benefits by Personnel, or fuel by the Transportation Department, etc., which is often the case when solid waste is part of a jurisdiction's operation. Future post-closure costs and sinking funds are established in enterprise accounting, and it possible to tell the cost for solid waste service and charge for it -- by the ton, by the household, by the business address, etc.

B. VARIABLE RATES

Local governments need to find ways to charge the generator for the service received in order to get solid waste costs out of the General Fund. Direct billing of customers for the solid waste service received is a key component of enterprise fund accounting. These fees, plus other revenues such as from the sale of recovered materials, make up the funds used to pay costs. Generator billing should be done in a way that encourages source reduction as well as maximizes diversion. A variable rate system (also called "unit pricing") goes far to accomplish this and is also an important part of enterprise accounting for solid waste management. Variable rate pricing has been the norm in commercial collection for years -- the generator is billed based

either on the weight of the material collected by the hauler, or by the size of the waste storage container used by the generator. For the residential customer, it can mean higher costs for more waste, or lower costs for less waste and more recycling. For the commercial generator, it can mean differential fees (or no fee) for loads that can be recycled. As consumerism is applied to solid waste services, the generator will have incentive to dispose of less and to set aside more materials for recycling. An example of a variable rate fee system is provided in Appendix A, Case Study of the City of Seattle.

C. COSTS FOR SOLID WASTE SERVICES

The solid waste dollar goes to many functions, depending upon the make-up of the specific system. Shown in Figure E-1 is a pie chart, developed from data from several cities, that graphically portrays how the solid waste dollar is split up. Administrative costs for each of the components are included in each portion of the pie. As can be seen, collection-related costs comprise over 60 percent of the pie, followed by disposal at 30 percent, and lastly by processing at 8 percent. It should be noted that solid waste collection includes bulk waste and special collections (such as post-special event collections and disaster debris), while recycling collection costs include yard waste collection as well as curbside service for materials. The pie chart shows recycling-related collection costs at 20 percent -- or almost one-third of the collection expenditures. Recycling costs overall can represent over one-quarter of the way the solid waste dollar is spent.

In addition to the above service-related and direct administrative costs, a community can expend considerable funds on specialized services, such as Household Hazardous Waste (HHW) collection and public information campaigns to encourage recycling and HHW diversion. Many communities have turned to surcharges on landfill or transfer station tipping fees as a means of funding new diversion programs, particularly for programs such as HHW that have a high unit cost and do not produce revenues to help pay for the program. Monies collected through surcharges can "get lost" in the General Fund; enterprise fund accounting can keep these resources dedicated to solid waste management programs.

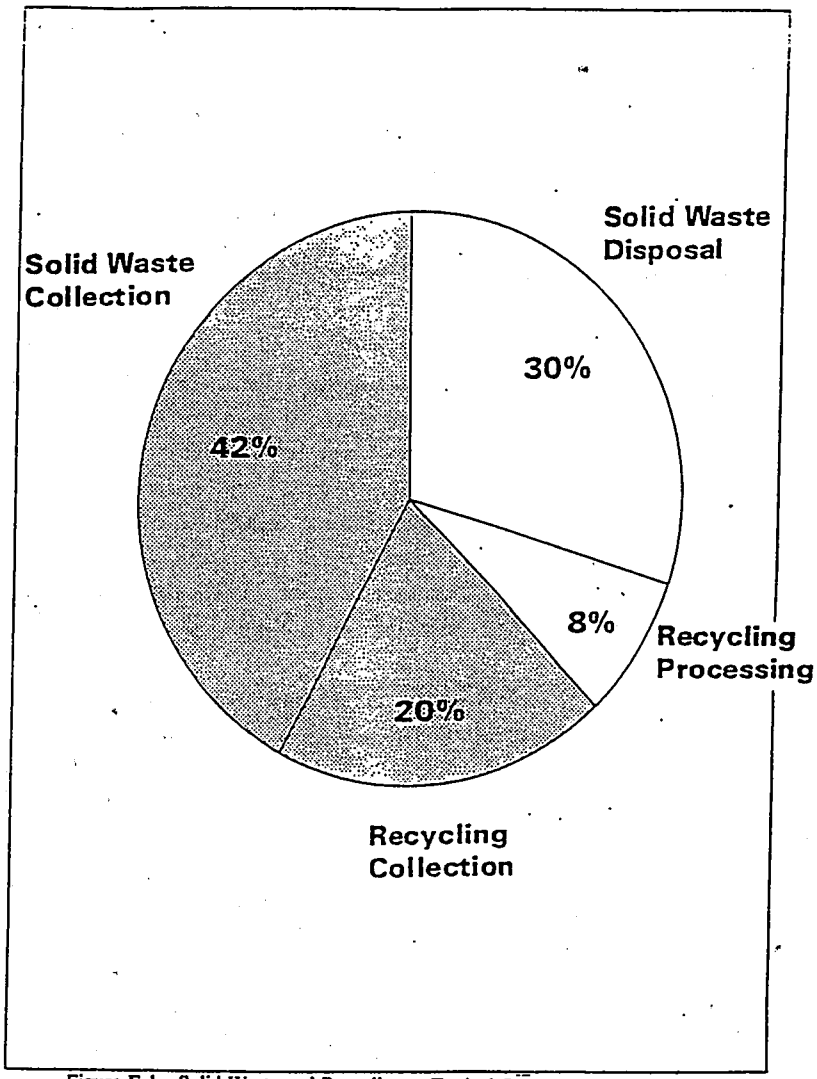

Figure E-1. Solid Waste and Recycling -- Typical System Cost Components

D. FACTORS INFLUENCING COSTS

Trends that influence recycling and solid waste disposal costs are discussed in various Report Chapters, and are summarized here by the service component. Overall, the cost of solid waste management is rising, but offsetting trends are discussed as well.

1. Collection

Two factors are driving the cost of solid waste collection. First, obtaining high-quality recyclables from the waste stream often means curbside collection of source-separated designated materials. This adds specialized recycling collection trucks and personnel routed through the same neighborhoods as the solid waste collection packer trucks. Yard wastes are also collected through a separate route system. Bulk wastes may also be collected separately using open-bed trucks equipped with a grapple. Each additional collection system will increase the number of trucks and personnel needed to get the job done.

Second, as the solid waste management system has evolved, the equipment industry has been evolving along with it. Automated collection equipment allows a single driver to complete a route, rather than the two- or three-man crews required for traditional packer trucks. Sophisticated routing software and GIS mapping allow a jurisdiction to consolidate routes, so that as recycling collection expands, solid waste collection routes can be adjusted proportionally, and optimum routes (i.e., the most material in the least time) can be devised for each type of collection. Other equipment features, such as split packers, allow a single truck to perform double duty while on a route. These options can be used to reduce the cost of collection.

Communities are innovating to contain the costs resulting from these trends. Automated collection has been applied to recyclable materials as well as refuse. Rebanco in Seattle has utilized authomated recycling collection in 96 gallon carts and reduced the collection frequency to once per month. Guelph, Ontario is implementing wet/dry collection citywide in the city, with a population of 80,000. This followed an extensive pilot program to establish the cost and effectiveness of the program. Because the collection function represents a majority of the solid

waste management cost, efficiency in this area has the largest reduction in overall cost for the investment.

2. Transfer

Collection costs can also be contained by adding transfer station(s) to the system. As discussed in Chapter IX, transfer stations can reduce collection costs by keeping collection packer truck routes as short as possible (less than 30 miles). A transfer trailer can carry three times the amount of waste as a packer truck and rail cars can carry six times the amount. Shifting the waste to larger-capacity, more efficient transfer vehicles for transport to the disposal site reduces the number of personnel and vehicles needed.

Even though transfer operations add capital and operations costs for transfer stations and vehicles, they have the potential to significantly reduce the overall cost. The reduction in the non-productive time for the route collection trucks has a double pay-off. First, the cost per collection route is reduced and second, the route collection trucks can collect from additional routes. This lowers the investment in trucks and crews.

3. Solid Waste Disposal

Class III Sanitary Landfills are still the primary method of managing solid waste in Los Angeles County. The cost of landfill disposal is a political issue as well as a technical one. The true cost of local landfill disposal is not reflected in $20.00 per ton tipping fees. Some long-term costs of landfill disposal can be deferred (rather than paid out of tipping fees), particularly closure, post-closure, and Title V Remediation Funds, plus, for existing landfills, the cost of the site may have already been paid for and does not reflect current land values. However, a jurisdiction may choose to keep landfill prices low in order to keep waste from leaving to lower-cost disposal sites in order to maintain cash flow at the landfill, or (as in the case of Orange or Riverside Counties) may reduce the price to attract waste from outside the jurisdiction and thus increase cash flow in the short term.

The actual cost of landfill disposal is driven by the cost of the land, pre-development costs for planning and permitting, plus the construction and operation costs of the facility over its life. The U.S. EPA promulgated new rules for landfill management on October 9, 1991. These rules, as subsequently adopted by the State of California, set standards for:

- Location. Includes limits on proximity to airports, 100-year floodplains, wetlands, fault areas, seismic impact areas, and unstable areas.
- Design. Requires composite liner and leachate collection systems to maintain less than 30-cm depth of leachate over liner. Liner systems combine compacted clay and synthetic membranes. Leachate collection piping is sandwiched in a porous layer between liners.
- Operations. Requires exclusion of Hazardous Wastes and bulk or uncontainerized liquid wastes, daily cover and control of disease vectors, methane gas monitoring and control and other air emissions control (i.e., no open burning), access restrictions to prevent illegal dumping, control of precipitation run-on and runoff, and recordkeeping for groundwater monitoring, methane gas, inspection reports, and closure/post-closure plans. No discharges to surface water are permitted.
- Groundwater Monitoring. Monitoring wells required within compliance area. Testing required for 62 pollutants (15 heavy metals and 47 volatile organic chemicals). If pollutants exceed background levels, testing must be conducted for another 245 hazardous inorganic and organic constituents. If specified levels of pollutants found, a corrective action procedure must be initiated.
- Closure and Care. Written closure plan required. Closure include a cap designed to minimize infiltration and erosion, including infiltration layer minimum of 18 inches and permeability no greater than $1x10^{-5}$ cm/sec of material. Care of the facility required for 30 years after closure, including regular inspections for cap integrity and well monitoring.
- Financial Assurance. Must provide detailed estimates of costs for closure and post-closure and to perform corrective action as required; must provide an acceptable mechanism to guarantee funding for these future activities.

In addition to the cost of the modern sanitary landfill, the State of California requires landfills to fund Article V Remediation Costs. Article V regulations require establishment of a fund to cover potential remediation of contaminated groundwater caused by landfills.

The impact of these rules has been to increase the cost per acre of constructing landfills; this, in turn, has resulted in a trend toward development of very large landfills that can keep costs down through the larger volume of waste that can be disposed of at the site. Given the size of these new landfills, there is a parallel trend toward developing new facilities in remote areas with rail or highway access where land is cheaper and large tracts available.

4. Processing

Through the 1970s and 1980s, transformation, or waste-to-energy, facilities were seen as a preferred alternative to increasingly scarce and costly landfill disposal. Facilities financed and built during that period have tip fees in the $30.00 per ton range. As a result of changes in tax law as well as increased air pollution control requirements, tip fees for new facilities would be close to $100.00 per ton.

Trends in recycling markets are discussed in detail in Chapter VII, Section B. There is a present downturn in markets following on the heels of a rapid expansion. As in the case of other commodities, market prices and opportunities for recovered materials will fluctuate; however, it is expected that markets will remain strong as a result of new final market and export market development. The processing costs of materials recovery facilities (MRF) vary among communities and average $50 per ton according to a recent NSWMA study. This includes both the capital costs and the operations and maintenance costs. Revenues from the sale of materials can off-set these costs, depending on the markets.

Unlike other recyclable materials, the markets for yard waste compost products have yet to expand. Processors are producing good material; the problem lies more in learning to present the product in a manner acceptable to the potential major markets (farmers, horticultural firms, etc.). These markets have specific needs and require a proven product. The specifications for compost products derived from waste materials need to reflect the traditional soil amendments used by these markets (e.g., peat moss), so that the user can understand how the compost can be applied to their needs.

APPENDIX F

APPENDIX F. YEAR-BY-YEAR TABLES FOR LANDFILL CAPACITY PROJECTIONS

The following tables provide year-by-year projections of the waste generation and disposal rates for Los Angeles County. The last column in each table, Unsatisfied Need or Daily Disposal Capacity Shortfall, projects the amount of generated waste in excess of the available disposal capacity. The first year a value in the Unsatisfied Need column is greater than zero denotes the "crisis" year, when the quantity of waste generated is larger than the available disposal capacity. As the tables are modified (based on the incremental adjustments discussed in Chapter V, Chapter VI, and Chapter VIII), the "crisis" year is postponed. Ultimately, the solid waste disposal system for Los Angeles County is proven to have much longer useful life than originally projected.

APPENDIX G

APPENDIX G: INTERNATIONAL TECHNOLOGY APPLICATIONS

This Appendix was prepared by Dr. Eugene Grigsby and Dr. Leobardo Estrada, based on information provided by personal contacts supplemented by a literature search. Included in this review are London, England; Hong Kong; and Japan. These international sites display in varying degrees characteristics that make their circumstances applicable to issues in Los Angeles County, including size of population, population densities, economic and social conditions, and level of technical sophistication.

As can be seen from the following writeups, use of landfills is the most common method of municipal solid waste (MSW) disposal. The issue of dwindling disposal capacity is a problem for all three of the locations examined. Recycling is receiving a major push, as is reuse of existing landfills. In Japan, waste-to-energy is a major alternative to the use of landfills. It would appear that London will increasingly turn to waste-to-energy to solve its growing landfill capacity problem. It should also be noted that in Japan a downturn in the economy had a dramatic impact on the volume of waste generation.

Lessons for Los Angeles

1. Economic downturn significantly impacts waste generation. Los Angeles is still in the throes of a recession; therefore, previous projections relative to waste generation are no longer valid.

2. Population growth and population composition also directly affect the waste stream. The rate of growth has slowed and the number of lower-income households have increased, thus the previous projections of waste generation are no longer valid. (Note that in Hong Kong, where there are a large number of low-income households, the majority of the waste is from commercial and industrial sources).

3. No world class city has found a single quick, easy solution to solid waste management.

4. Alternatives to utilization of landfill are being strongly encouraged and implemented.

5. Strategies include a combination of reuse of older landfill sites, recycling and waste-to-energy with minimal reliance on landfills.

A. LONDON

The 1995 population of Greater London, England is 6.8 million. The population density in the City of London is 10,429 people per square mile.

Households in London produce on average 1.2 tons of waste per year. The 33 London local authorities collect 3.7 million tons of household and commercial waste annually. The London Waste Regulation Authority (LWRA) is responsible for supervising four statutory waste disposal authorities and three voluntary groups. The LWRA is also responsible for supervising and licensing the disposal of an additional 8.8 million tons of waste handled by private waste disposal companies. The LWRA also has responsibility for regulating the annual disposal of 129,000 tons of hazardous waste. Figure D-1 shows that in 1993-94, 5 percent of the waste was recovered, with the remainder disposed of in landfills.

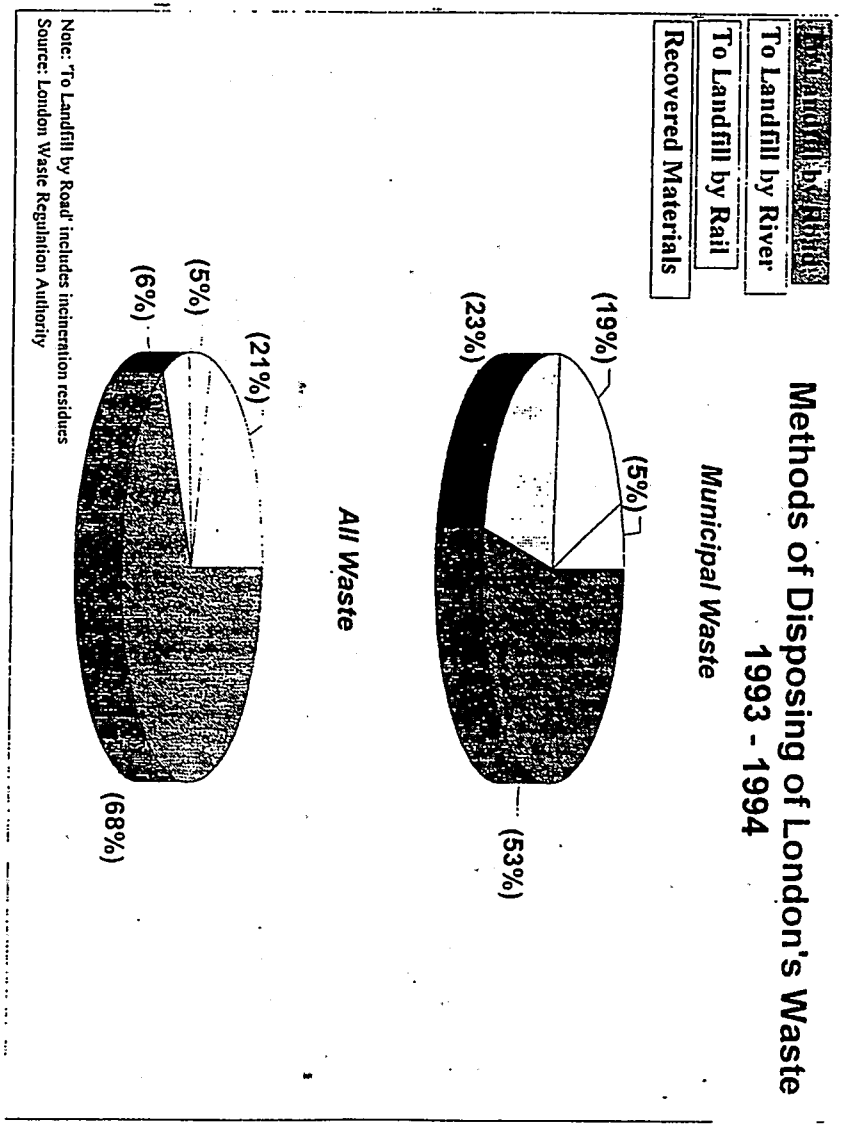
Approximately 90 percent of London's waste is placed in landfill sites outside of the City's boundaries. According to the LWRA's recently produced report, *Today's Waste, Tomorrow's Resources: The Waste Management Plan for Greater London 1995-2015*, waste disposal in London should be based on a hierarchy of waste management: waste prevention and re-use, waste recycling and energy recovery, and the safe disposal of non-recoverable residues. Increased emphasis is being placed on waste reduction and recycling.

By the year 2000, it is anticipated that 25 percent of all household waste in London will be recycled. However, only 20 percent of the total municipal solid waste stream is anticipated to be recycled in London by the year 2005.

Use of landfills will remain the most viable disposal option, but the Authority recommends that no new landfill sites accepting putrescible waste be permitted. The Authority recognizes that new landfill sites will be difficult to obtain and, therefore, recommends the reuse of existing sites.

For the last 20 years, London has had only one municipal waste combustion facility. A new waste-to-energy combined heat and power plant is under construction. It is anticipated that construction of additional waste-to-energy facilities will have a significant effect on the need for landfills by reducing each ton of raw waste to approximately 0.30 tons of ash.

B. HONG KONG



Hong Kong has experienced explosive growth in the past. This rate has slowed down, probably due to the impending transfer of government to mainland China in 1996. A population increase of only 5 percent is projected for the years 1991-2000. The 1995 population is 5.8 million, in a total area of 409 square miles (including the New Territories as well as the City of Hong Kong). The population density of the City of Hong Kong is the highest in the world. In 1994, about 3 million tons of municipal solid waste generated from homes, offices and factories ended up in garbage bins. The waste could grow to 4.8 million tons by the year 2006. Composition of Hong Kong MSW is shown in Figure D-2.

Three-quarters of the solid waste and nearly all of the hazardous chemical waste are generated by industry and commerce. Much of this is demolition debris, and the government has initiated a recycling program for this material. However, it is estimated that over half of the waste currently disposed of at landfills could be diverted for land reclamation purposes. Recovery and recycling of reusable materials will also become more attractive as waste producers seek to minimize their waste disposal bills.

The government has embarked on a program to recover costs of waste disposal services directly from the users. Until recently, there has been no fee for disposal at the landfills. The initial scheme for recovering costs, both for landfill disposal and for services provided by the Chemical Waste Treatment Center, is to create economic incentives for waste producers to practice waste management and to exploit waste recycling and reuse opportunities. In addition, Hong Kong is planning several waste-to-energy facilities to supplement their three landfills.

Figure G-1

Methods of Disposing of London's Waste
1993 - 1994

Note: 'To Landfill by Road' includes incineration residues
Source: London Waste Regulation Authority

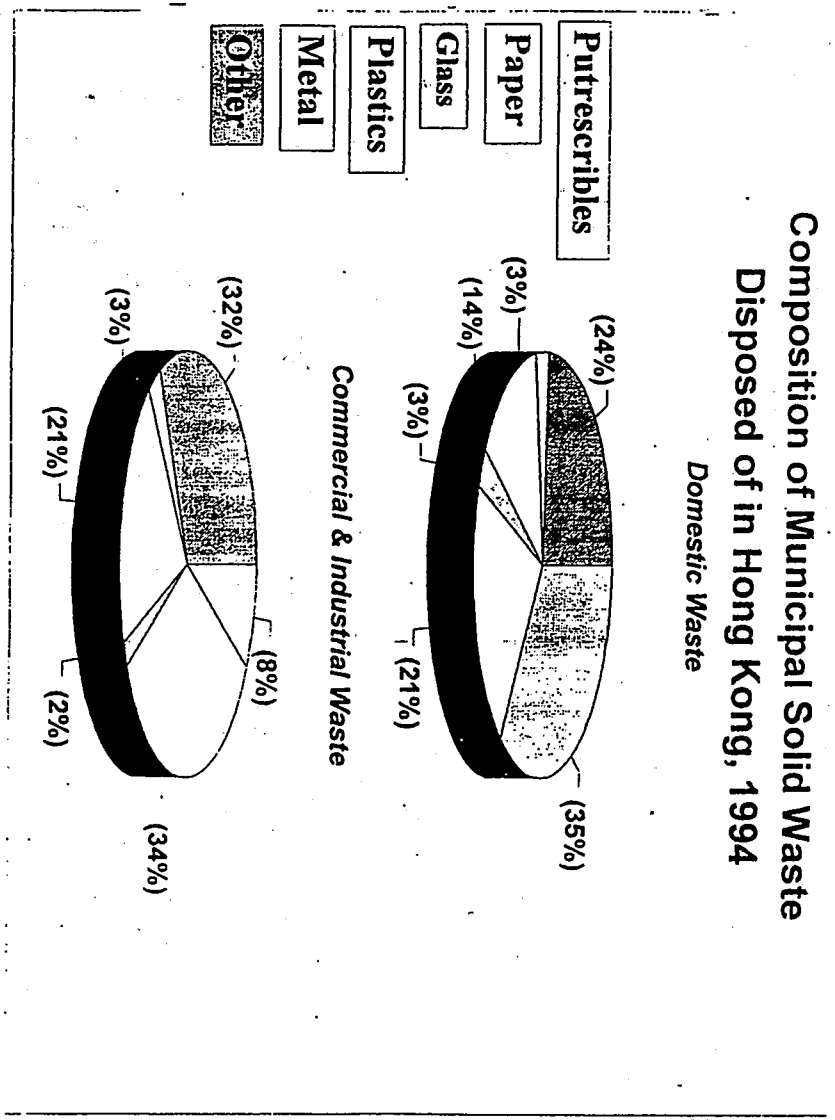


Figure G-2

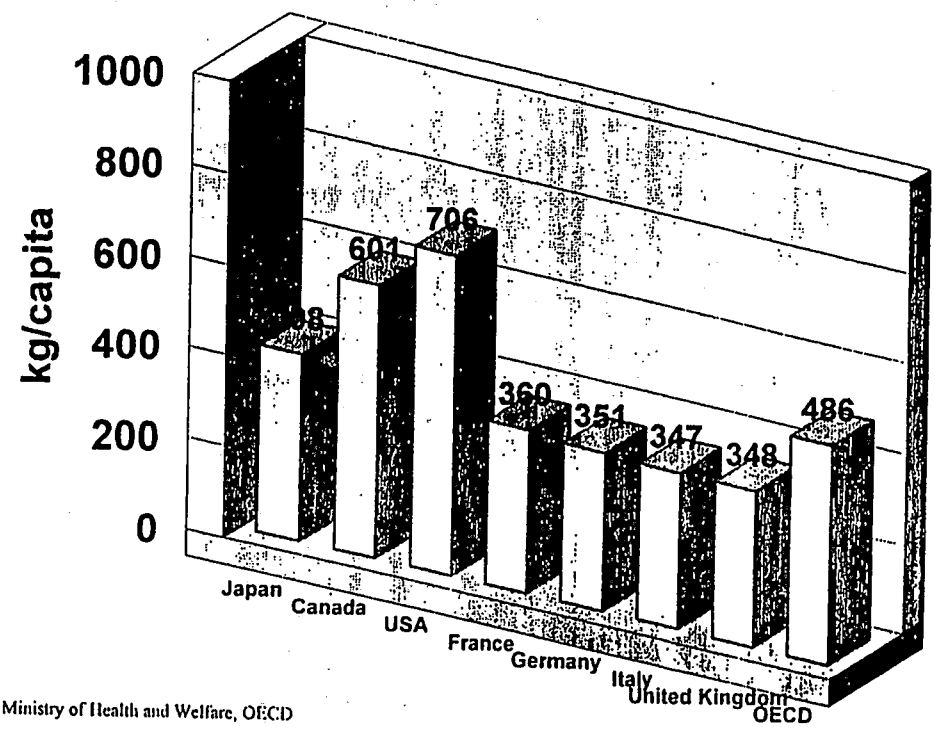
Preliminary findings from a 1994 survey conducted by the Hong Kong Waste Disposal Authority indicates that current recovery and recycling activities in Hong Kong account for 53 percent of the total waste generated by commercial and industrial sectors. This suggests a very significant and robust level of recycling activity. However, the corresponding figure for the domestic sector is only 8 percent.

C. JAPAN

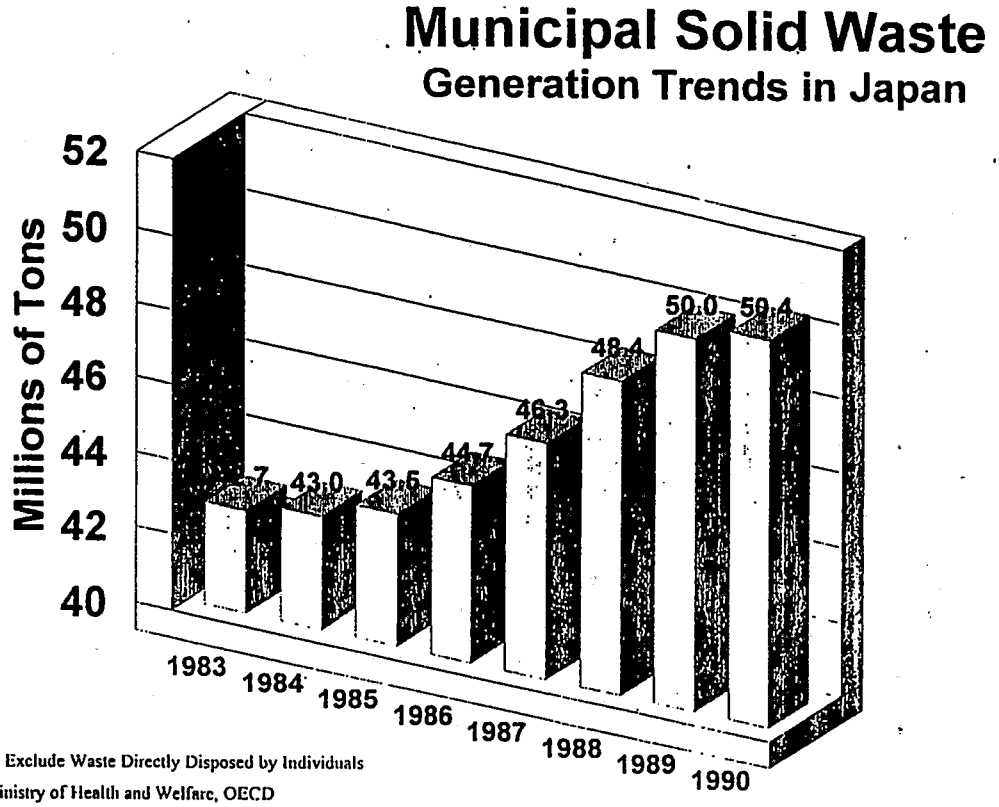
The islands of Japan comprise approximately 144,000 square miles, with a population density of 868 persons per square mile. The 1995 population is 125.1 million, of whom 77 percent are residents of urban areas. The amount of MSW generated in Japan increased at a rate of about one percent per year between 1975 and 1985. However, in the following four years, MSW grew nearly four percent annually to reach about 50.4 million tons in 1990. While no national data are available beyond 1990, the Tokyo metropolitan government reports that MSW decreased from a peak of 4.9 million tons in 1989 to 4.7 million tons in 1991. This annual two percent drop is attributed primarily to the economic downturn the country has experienced.



Japanese MSW generation levels per capita compare favorably with those of a number of other Organization for Economic Cooperation and Development (OECD) countries, but the rate of increase in the late 1980s was among the highest in the OECD. Figure D-3 shows per capita waste generation rates for OECD countries in 1990. Much of the growth in MSW generation since 1986 has been in the commercial sector, e.g., copier, telefax and office automation discards. The increase in waste generation from 1985 through 1990 is shown in Figure D-4.

The objectives of Japanese MSW management are:

"To control the discharge of waste, to perform appropriate waste sorting, storage, collection, transportation, recycling, disposal and so forth, and to cleanse the living environment in order to preserve it and improve public health."



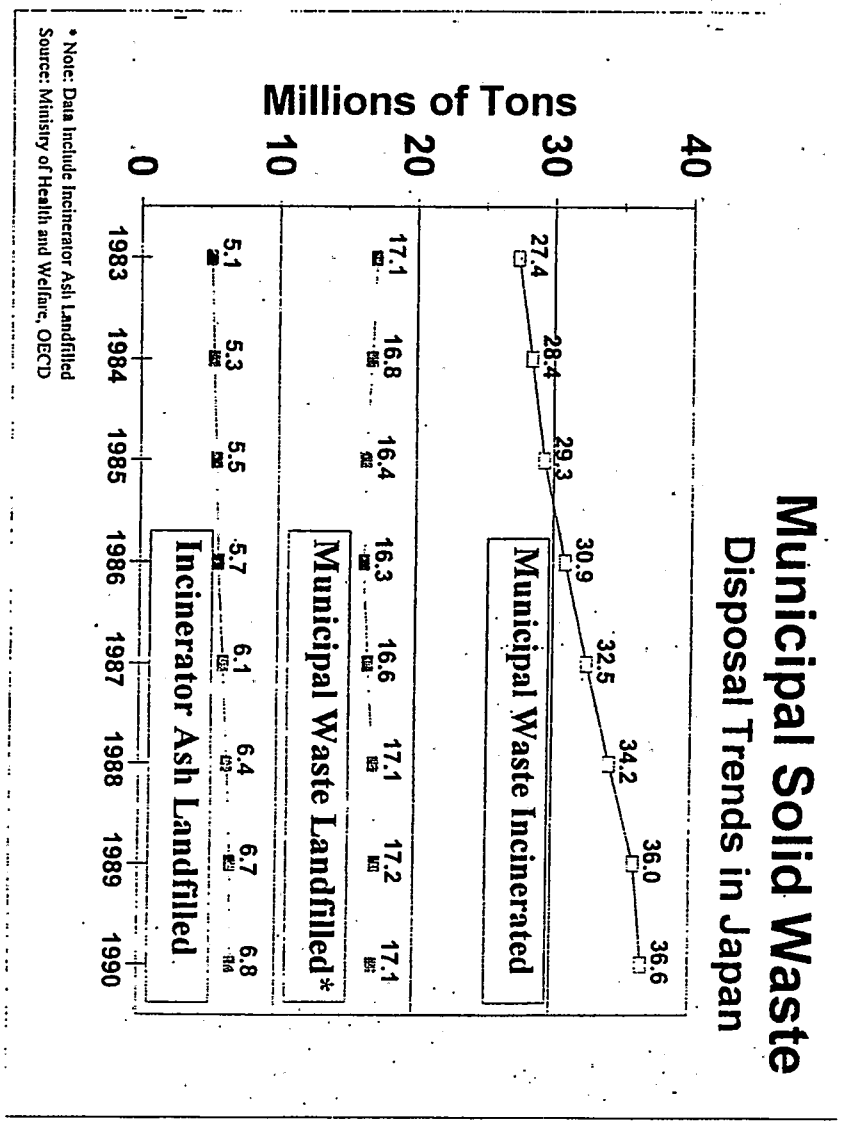
(Reference 1, OECD, p. 52)

Figure G-3. Municipal Solid Waste
State, 1990

Source: Ministry of Health and Welfare, OECD

Figure G-4

Note: Data Exclude Waste Directly Disposed by Individuals



Source: Ministry of Health and Welfare, OECD

The Japanese concept of waste reduction is essentially to cut the amount of waste disposed of in or on the land. Waste separated at source for reuse or recycling counts as waste reduction. Since the shortage of landfill capacity is serious, the primary purpose of promoting resource recovery, recycling and reuse in Japan is not to conserve resources or to reduce imports but rather to reduce the amount of waste going to landfill. Disposal trends from 1983 through 1990 are shown on Figure G-5.

Japan's heavy reliance on waste-to-energy can be explained by its objective of avoiding landfill while assuring environmentally sound disposal. About 75 percent of MSW is combusted. Combustion reduces the mass of MSW by roughly 82 per cent and its volume by over 95 per cent. Since the ash is landfilled along with untreated MSW, and landfill life depends on volume, the ash represents a relatively small burden on national landfill capacity. Japan has addressed some of the issues related to siting by operating extremely clean facilities equipped with state-of-the-art emission controls. Also, the plants are aesthetically designed and co-located with desirable land uses such as recreation centers and swimming pools.

Current landfill capacity for MSW is expected to be exhausted before the turn of the century. Capacity shortage has led to illegal dumping of MSW and industrial waste. Because of this illegal dumping problem, Japan has decided that 84 percent of MSW must be processed for reduction through waste-to-energy or crushing by March 1996. This will mean adding seven million tons per year of waste-to-energy capacity over the next three years. In addition, the Japanese are building industrial waste treatment plants and night soil and septic tank sludge facilities.

APPENDIX H

APPENDIX H: TABLES AND METHODOLOGY USED FOR DIVERSION RATE CALCULATIONS

The annual diversion rates for Los Angeles County were projected by identifying the composition of the waste stream and the individual diversion rate for each waste component. The waste steam composition for each generating sector (residential, commercial, and industrial), which is shown as Table H-2, was taken from the *Source Reduction and Recycling Element for Unincorporated Los Angeles County* (County of Los Angeles Department of Public Works, December 1991).

The anticipated diversion rate for each component of the waste stream is based on three levels of recycling effort. The diversion rates associated with each of the levels (and for each generating sector) is shown as Table HG-3. The various levels of recycling intensity are discussed in detail in Chapter VII. The current diversion rate, Level 1, is based on the current recycling effort. The individual diversion rates for each waste component are typical diversion rates experienced by other communities and are based on the overall diversion. Levels 2 and 3, which are anticipated to be reached in years 2000 and 2005 respectively, represent incremental increases in the intensity of recycling efforts. Similar to Level 1, Levels 2 and 3 represent typical diversion rates experienced by other communities at equivalent recycling levels of intensity.

Table H-1 shows the projected annual diversion rates for Los Angeles County. The first step in identifying the diversion rates is dividing the total waste stream into the three major generating sectors, residential, commercial, industrial. The percentages for each sector were taken from the *Source Reduction and Recycling Element for Unincorporated Los Angeles County* (SRRE). The SRRE includes a miscellaneous sector, which generates 3.2 percent of waste stream. This 3.2 percent was divided into prorated fractions and added to the residential, commercial, and industrial sectors. For the purpose of diversion rate estimates, the percentage of waste generation allocated to the residential, commercial, and industrial sector were 50.6, 32.3, and 17.0 respectively.

After the total waste stream is divided into the three generating sectors, which are shown as the third, fourth, and fifth column of Table H-1, the waste from each generating sector is multiplied by the composition percentages from Table H-2. The annual generation of each waste component (for each generating sector) are listed in Appendix Tables H-4 through G-18. Adjacent to each generation rate is the diversion rate, taken from Table H-3. The diversion rates are assumed to increase linearly between the different Levels of recycling intensity.

For each year in Tables H-4 through H-18, the generation of each waste component is multiplied by the respective diversion rate. The summation of these products is total amount of waste recovered from the generating sector. The annual amount of recovered waste is shown in the last column of Tables H-8 (residential), G-13 (commercial), and G-18 (industrial). These values are also included in Table H-1 and a corresponding diversion rate by generating sector is provided. The recovered wastes from each generating sector are added together in the second to last column in Table H-1. Dividing this value by the total waste generation rate provides the annual percent diversion rate.
