This section also establishes a schedule for inspections by the EPA of various facilities: the EPA must annually inspect facilities owned or operated by a state or federal agency, *id* § 6927(c)-(d) (Supp. IV 1986), and it must inspect at least every two years every facility that has been issued a permit under RCRA section 3005, as amended, *id* § 6927(e)(1)

RCRA section 3013, 42 U.S.C. § 6934 (1982), provides that if the EPA receives information indicating that hazardous waste exists at a facility or site that may present a substantial hazard to human health or the environment, the EPA may issue an order requiring the owner or operator to monitor, test and analyze such conditions and report them to the EPA. *Id* § 6934(a).

391. *See* E.R.C, RCRA HANDBOOK 12-13 (2d ed. 1986) (Figure A: States with Final Authorization), *see also* 42 U.S.C. § 6926 (1982 & Supp. IV 1986).

392. The Hazardous and Solid Waste Amendments of 1984, Pub. L. No. 98-616, 98 Stat. 3221 (codified in scattered sections of 42 U.S.C.).

393. 42 U.S.C. § 6924(g)-(h) (Supp. IV 1986). EPA must review its lists of hazardous wastes at a rate of one-third by August 8, 1988, two-thirds by June 8, 1989, and all by May 8, 1990. *Id* § 6924(g)(4)

394. *Id* § 6924(o)

395. *Id* Regulations promulgated pursuant to this section must be revised from time to time to take into account technological advances made in the control and management of hazardous wastes. *Id*

396. *Id* § 6922(b). This amendment requires a generator to certify that it has a program in place to reduce the volume and toxicity of hazardous waste to the degree determined by the generator to be economically practicable. *Id* The 1984 amendments represent the first congressional statement on hazardous waste minimization. Although the amendments require companies to report on their current and planned waste reduction efforts, no standards are mandated. This represents an attempt to encourage alter-

age, RCRA is evolving into a more prophylactic and comprehensive waste management statute.

The legal applicability of RCRA is launched on a triple trigger. First, the specific requirements of RCRA apply to any "person," which includes an individual, federal agency, government corporation, state, municipality, commission, political subdivision of a state or interstate body.[397]

Second, only persons generating at least de minimus quantities of hazardous waste are subject to RCRA's requirements. At a particular site, hazardous waste must be created in amounts greater than 100 kilograms per month in order to invoke RCRA's primary coverage.[398] Small quantity generators exempted by this threshold include an estimated ninety-two percent of all hazardous waste generators in the nation, and they generate at least five percent of the total volume of hazardous waste.[399] Generators and transporters exceeding these threshold amounts must keep a manifest system to track wastes and must follow strict labeling, recordkeeping, and groundwater monitoring requirements.[400] A different set of standards and recordkeeping requirements applies to owners and operators of hazardous waste treatment, storage, and disposal sites.[401] Both civil[402] and criminal[403] penalties may be imposed for violations of RCRA requirements.

Third, only certain substances are defined as hazardous wastes subject to the full scope of RCRA regulation. As explained below, a

natives to land disposal of hazardous wastes. *See* 40 C.F.R. pt. 262 (1988); 50 Fed Reg. 28,702 (1985); SERIOUS REDUCTION, *supra* note 58, at 45, 158.

Ten states have currently established waste reduction programs: California, Connecticut, Georgia, Illinois, Minnesota, New York, North Carolina, Pennsylvania, Tennessee and Wisconsin. SERIOUS REDUCTION, *supra* note 58, at 34-35. A study of source reduction possibilities for southern California has been proposed. *See Two-Year, $600,000 Source Reduction Study Planned by EDF, Southern California Utility*, 17 Env't Rep. (BNA) 1794 (Feb. 20, 1987).

397. 42 U.S.C. § 6903 (1982).

398. *Id.* § 6921(d)(6) (Supp. IV 1986). Section 6921(d) requires the EPA to promulgate standards under sections 6922, 6923, and 6924 to govern small quantity generators. A small quantity generator is a "person" who generates a total quantity of hazardous waste greater than 100 kilograms (about 220 pounds or one half of a 55-gallon drum) but less than 1000 kilograms during a calendar month. Although one who generates less than 100 kilograms of hazardous waste per calendar month is not subject to mandatory regulation, the EPA Administrator is left discretion to regulate the waste practices of such persons if necessary to protect the public health and environment. *Id.* § 6921(d); *see* 40 C.F.R. pts. 260-265, 270-271 (1988).

399. SUPERFUND STRATEGY, *supra* note 42, at 11.

400. 42 U.S.C. §§ 6922-6923 (1982 & Supp. IV 1986); *see supra* notes 385-86.

401. 42 U.S.C. § 6924 (Supp. IV 1986); *see supra* note 388.

402. 42 U.S.C. § 6928 authorizes the EPA to issue an order assessing civil penalties for past or present violations, including suspension or revocation of one's permit to handle hazardous wastes. The EPA may also commence a civil action against a violator in U.S. district court for appropriate relief, such as a temporary or permanent injunction. Fines may also be assessed up to $25,000 for each day that the violation exists. 42 U.S.C. § 6928(a), (c) (Supp. IV 1986).

403. 42 U.S.C. § 6928(d) provides that one who knowingly violates the requirements of RCRA is subject to a fine of up to $50,000 for each day of violation, or imprisonment of up to two years, or both, for their first conviction. If one is convicted more than once, the maximum punishment is doubled with respect to both fine and imprisonment. *Id.* § 6928(d).

substance must first qualify as a "solid waste" or as a combination of "solid wastes" to be classified as a hazardous waste under RCRA.[404]

b. RCRA and the EPA: Defining "Hazardous Waste"

RCRA defines "hazardous waste" as "a solid waste, or combination of solid wastes," which might contribute to increased mortality or illness, or might pose a substantial hazard to human health or the environment.[405] In turn, "solid waste" is defined to include "any garbage, refuse, sludge . . . and other discarded material."[406] This definition of solid waste includes waste in gaseous or liquid forms.[407]

RCRA instructs the EPA to "develop and promulgate criteria for identifying the characteristics of hazardous waste, and for listing hazardous waste."[408] Since RCRA's passage in 1976, however, the definition of "hazardous waste" has confounded the EPA. The definition has important implications that reach beyond the EPA's regulatory authority under RCRA. Designation of a substance as a hazardous waste under RCRA automatically triggers CERCLA liability when a release is threatened or occurs.[409]

The EPA proposed regulations for further defining hazardous wastes in December 1978[410] and published interim final regulations in May 1980.[411] The May 1980 interim final regulations defined solid waste as "any garbage, refuse, sludge, or any other waste material."[412] Pursuant to its statutory mandate,[413] the EPA issued further regulations specifically listing approximately 1000 chemicals and chemical compounds that have been determined to create present or potential risks prohibited by statute.[414] This list includes a number of compounds that are identified with leachate from MSW,

404. 42 U.S.C. § 6903(5) (1982).

405. *Id.*

406. *Id.* § 6903(27).

407. *See id.*

408. *Id.* § 6921 (1982 & Supp. IV 1986). Pursuant to this authority, EPA has: (1) listed generic and specific waste streams as hazardous, 40 C.F.R. §§ 261.3, 261.32 (1988); (2) listed certain commercial chemical products as hazardous if discarded or intended for discard, *id.* § 261.33; and (3) established four "characteristic" tests to assess the ignitability, corrosivity, reactivity, and toxicity of all other wastes, *id.* pt. 261, subpart C.

409. 42 U.S.C. § 9601(14)(C) (Supp. IV 1986).

410. 43 Fed. Reg. 58,946 (Dec. 18, 1978).

411. 45 Fed. Reg. 33,066, 33,093 (proposed May 19, 1980). The regulations were later revised in April 1983. 48 Fed. Reg. 14,472 (1983). The final rule was published in January 1985. 50 Fed. Reg. 614 (Jan. 4, 1985) (codified at 40 C.F.R. § 261.3 (1988)).

412. 45 Fed. Reg. 33,066, 33,093 (May 19, 1980). This definition is still in effect.

413. *See supra* text accompanying note 408.

414. 40 C.F.R. §§ 261.31, 261.32, and 261.33 list hazardous wastes from non-specific and specific sources which include organic chemicals, inorganic chemicals, inorganic pigments, pesticides, explosives, and petroleum refining by-products. 40 C.F.R. §§ 261.31-.33 (1988).

such as dichloroethylene, methylene chloride, trichloroethylene, and vinyl chloride.[415] Additionally, in certain circumstances MSW could qualify as ignitable, reactive, toxic, or corrosive—generic characteristics of any solid hazardous waste—depending upon the chemical constituents in the MSW.[416]

RCRA's provisions, as further delineated by the EPA's regulations, therefore include as hazardous waste the primary constituents of MSW. Consequently, municipalities that generate and collect MSW, owners and operators of MSW landfills, and transporters of MSW are required to comply with all applicable RCRA requirements, provided they handle more than a de minimus amount of waste.

c. The EPA's Exclusion of Household Waste

The EPA assumes that individual households generating hazardous MSW fall under the "small quantity" generator exception for RCRA compliance.[417] If a municipality is viewed as a "non-arranging" transporter of waste for a household, then arguably it is also exempt from RCRA transporter regulations. However, the small quantity generator exception would not apply to municipalities. Although individual households do not fall within RCRA reporting requirements, municipalities that collect and amass this same waste for disposal do not escape RCRA regulation.

However, the full sweep of RCRA is mitigated by regulatory exclusions that temper the broad statutory definition of hazardous waste. Among these exclusions is "household waste," defined as "any material (including garbage, trash and sanitary wastes in septic tanks) derived from households (including single and multiple residences, hotels and motels, bunkhouses, ranger stations, crew quarters, campgrounds, picnic grounds and day-use recreation areas)."[418] This exemption encompasses household waste that has been "collected, transported, stored, treated, disposed, recovered (e.g., refuse-derived fuel) or reused."[419]

This regulatory exclusion can be read to exempt MSW from RCRA regulations entirely, regardless of the volume of hazardous waste generated as a constituent of MSW. The EPA's use of the modifier "any" to denote the types of household wastes excluded appears to place any hazardous constituents of household waste beyond RCRA's reach, notwithstanding that they appear separately on the itemized RCRA list of hundreds of hazardous or acutely hazardous constituents. RCRA's legislative history sheds no light on Congress's intent either to include or exclude MSW from RCRA's requirements.

The EPA consistently takes the position that, despite the threat to the public, municipalities and transporters that generate and transport MSW to private landfills are exempt from responsibility for cleanup costs or damages under both RCRA and CERCLA.[420] Premising its conclusion on RCRA's regulatory exclusion of "household waste," the EPA's discretionary enforcement of RCRA excuses from CERCLA prosecution thousands of municipal, county, and state governmental entities at sites they do not own or operate.

2. Drawing the Line: CERCLA Substance Over RCRA Waste

Expanding RCRA's household waste exclusion to preclude EPA enforcement under CERCLA is legally and factually unsupportable under the existing statute. The drafters of CERCLA elected to include only a single citation to RCRA to incorporate by reference four external statutory lists of hazardous waste constituents.[421] Although Congress could have incorporated by reference larger portions of RCRA to effectuate and define CERCLA's purposes, Congress sought to incorporate only the RCRA hazardous waste list, without adopting the operative provisions of RCRA.

Of critical importance is the semantic distinction between RCRA and CERCLA in their designations of hazardous waste components. RCRA speaks in terms of "hazardous waste," from which the definition of "household waste" is regulatorily excluded.[422] CERCLA, on the other hand, addresses "hazardous substances," as incorporated by reference to the hazardous substance lists of four other statutes, including RCRA.[423] These four statutes defined their "hazardous" substance lists exclusively for internal regulatory purposes, without considering CERCLA or its ramifications. The "household waste" exclusion in RCRA is necessary to exempt MSW from burdensome RCRA recordkeeping requirements for hazardous "solid wastes."

CERCLA, however, does not recognize "wastes," but speaks only of "substances." For CERCLA purposes, there are no such things as "waste," "municipal solid wastes," "solid wastes," or "hazardous wastes." For CERCLA purposes one drop of a "hazardous substance" compels action, whereas under RCRA's principal requirements only large quantity generators merit plenary regulation.[424] Case law makes clear that it was not Congress's purpose when en-

415. *Id.* §§ 261.30-.33.

acting CERCLA to exclude minimum quantities of hazardous substances from regulation.[425]

The "household waste" exclusion in RCRA, however, is a regulatory invention rather than an exclusion contemplated by Congress. Nowhere in the statutory scheme or legislative history of RCRA are there exemptions for "household wastes," MSW, or any of its constituents. The RCRA regulatory exemption for "household waste" had not been promulgated in its final form when CERCLA was initially considered by Congress,[426] although the exemption does predate CERCLA's final passage.[427] In discerning Congress's intent, courts have stated that Congress is presumed to have knowledge of the legal interpretations accorded preexisting statutes.[428] However, Congress apparently neither recognized nor accepted the inclusion of the RCRA "household waste" exclusion as part of the design and structure of CERCLA, and indeed contemplated that the plenary scope of CERCLA would reach the household garbage pail.[429]

425. In a CERCLA action the government must prove only that the defendant's substance was deposited at the site in question. United States v. Conservation Chem. Co., 619 F. Supp. 162, 185 (W.D. Mo. 1985); United States v. Wade, 577 F. Supp. 1326, 1332 (E.D. Pa. 1983). The defendant's waste is hazardous if it contains any amount of a substance listed as hazardous under the various definitional statutes incorporated by reference in CERCLA. *See Conservation Chemical*, 619 F. Supp. at 228; *Wade*, 577 F. Supp. at 1339-40. No specific amount of a hazardous constituent is necessary to qualify waste as a hazardous substance under CERCLA. *See* 42 U.S.C. § 9601(14) (Supp. IV 1986).

426. The regulation containing the "household waste" exclusion was promulgated on May 19, 1980, 45 Fed. Reg. 33,084, to be effective on November 19, 1980.

427. CERCLA was signed by President Carter on December 11, 1980. 126 CONG. REC. 34,415 (1980).

428. United States v. Stringfellow, 20 Env't Rep. Cas. (BNA) 1905, 1909 (C.D. Cal. 1984); *see also* United States v. Medley, 24 Env't Rep. Cas. (BNA) 1856, 1857 (D.S.C. 1986) (noting that in enacting CERCLA, Congress was aware that a majority of states allow a right to contribution when joint and several liability exists); United States v. Conservation Chem. Co., 619 F. Supp. 162, 199 (W.D. Mo. 1985) (stating that courts may presume that Congress is aware of common law interpretations of statutes).

429. In a critical floor statement, Representative David Stockman presented his understanding that CERCLA would apply to MSW and to many household products:

> The point is, there are no standards at all, and the coverage, the scope of this bill, is plenary. It covers every waste site, every junk yard, every municipal dump in the country, including those on private property.
>
> . . . .
>
> . . . The point is that by defining the scope of the act [by reference to the Resource Conservation and Recovery Act] what we do is incorporate the definition of hazardous material from the existing Resources Recovery and Conservation Act [sic] . . . . I do not believe that very many of my colleagues have looked at the list of 1,165 different materials, chemical compounds, and trade names that are on the RCRA list . . .
>
> . . . I would like to take a minute of the time of the House this afternoon just to read and put in the RECORD some of the materials that are considered hazardous under RCRA, and which are found in every waste site, every dump site, every municipal landfill, in the country.
>
> First, let us start with some household names that are going to end up in any municipal landfill:
>
> Mole Death; Mouse-Nots; Mouse-Bid; Mouse-Tox; Pied Piper Mouse Seed; Rat and Mice Bait; Rat-A-Way; Rat-B-Gon; Rat-O-Cide, Rat Guard, Rat-Kill; Rat-Mix; and Rats-No-More.
>
> The list goes on and on. This is household refuse, but under the definition of RCRA it is hazardous material, and by incorporation into this act, if it is found in any site, then the superfund authorities take effect.

To interpret the possible reach of CERCLA to MSW, one must decide whether RCRA overrides CERCLA. If the MSW exemption in RCRA regulations is incorporated in CERCLA, there is a defensible argument that CERCLA also exempts MSW from its coverage. On the other hand, if CERCLA only incorporates by reference certain limited waste definitions of RCRA, MSW contains potentially hazardous substances subject to CERCLA. This interpretation must be one or the other: CERCLA either does or does not universally apply to MSW.

A substance is hazardous under CERCLA if it is included in any definitional reference and not otherwise specifically excluded by CERCLA. RCRA's exclusion of household hazardous waste does not appear to exempt hazardous constituents of household waste from CERCLA prosecution. Congress has made no mention of exempting household waste from CERCLA's reach.

B. Judicial Constructions of RCRA and CERCLA

Courts have not yet addressed whether CERCLA section 101(14), which incorporates by reference RCRA's list of hazardous wastes, adopted only the hazardous waste component list or whether CERCLA also adopted RCRA's regulatory exclusion of MSW from recordkeeping requirements. Legislative history does not support the view that Congress intended to transfer regulatory exclusions when it incorporated by reference specific statutory provisions in CERCLA.[430] This question closely parallels the debate over whether RCRA's statutory exclusions for generic materials such as "fly ash," "mining wastes," or "coal tar"[431] also exclude these materials from CERCLA regulation if they contain hazardous constituents listed in other statutes. To date, the courts have held that CERCLA imposes liability regardless of RCRA exemptions.

In *Eagle-Picher Industries, Inc. v. EPA*,[432] petitioners argued that their waste materials, including mining waste and fly ash from large boilers, were not a "hazardous substance" for purposes of CERCLA remediation liability.[433] They based their argument on the fact that CERCLA draws its definitions from reference to other statutes, in-

126 CONG. REC. 26,759 (1980) (statement of Rep. Stockman).

Stockman went on to discuss the disposal of methanol (rubbing alcohol), naphthalene (mothballs), formaldehyde and saccharin (all RCRA hazardous wastes) in municipal landfills. *Id.*

430. *See generally* Dedham Water Co. v. Cumberland Farms Dairy, Inc., 805 F.2d 1074, 1080 (1st Cir. 1986) ("CERCLA has acquired a well deserved notoriety for vaguely drafted provisions and an indeterminate, if not contradictory, legislative history.") (quoting United States v. Montello, 605 F. Supp. 898, 902 (D.N.H. 1985)).

431. *See* 42 U.S.C. § 6921(b)(3)(A) (1982).

432. 759 F.2d 922 (D.C. Cir. 1985).

433. *Id.* at 926-27.

cluding the Solid Waste Disposal Act.[434] This statute specifically excludes both mining waste and fly ash from RCRA regulation.[435] Petitioners argued that this exemption under RCRA was imposed upon CERCLA because CERCLA's list of hazardous substances was defined by reference to RCRA.[436] CERCLA's reference to RCRA statutorily excludes "any waste the regulation of which under the Solid Waste Disposal Act has been suspended by Act of Congress."[437]

The EPA, however, argued that this exclusion applies only to hazardous substances so designated by the Solid Waste Disposal Act.[438] Seeking to include regulation of the compounds under CERCLA, the EPA argued that this exclusion " 'speaks only to the question whether mining wastes (and other "suspended" wastes) are CERCLA "hazardous substances" *because they are regulated under RCRA.*' "[439] Thus, a question of statutory interpretation was at issue, guided only by the sparse legislative history accompanying a hastily passed statute.

In *Eagle-Picher*, the D.C. Circuit held that, unless ambiguous, the plain language and structure of CERCLA's statutory scheme must control the court's interpretation of congressional intent.[440] In this case, the plain language and structure of CERCLA restricted a statutory exclusion relevant to only the definitional section. If a chemical compound qualifies under one of the three other statutes referenced by CERCLA section 9601(14) to define hazardous substances, the exclusion from one statute does not control the others.[441] Thus, should any chemical or compound qualify as a hazardous substance under one of the four statutes referenced by CERCLA's definition, it is not controlling that the substance is statutorily excluded as a hazardous substance under another.[442]

The definitional provision of CERCLA is therefore a multiple trigger. Inclusion of a substance in any one of the definitional reference statutes is sufficient to define the substance as hazardous, notwithstanding the substance's exclusion elsewhere.[443] Two courts have

434. 42 U.S.C. §§ 6901-6991(i) (1982 & Supp. IV 1986).

445. *See* United States v. Wade, 577 F. Supp. 1326, 1339 (E.D. Pa. 1983) (noting that CERCLA liability for hazardous substances regulated by the Federal Water Pollution Control Act, 33 U.S.C.A. §§ 1251-1387 (West 1986 & Supp. 1988), will be dependent upon concentration levels listed by CERCLA).
446. *Eagle Picher*, 759 F.2d at 927-28.
447. *See* United States v. Carolawn Co., 14 Envtl. L. Rep. (Envtl. L. Inst.) 20,696, 20,697 (D.S.C. 1984).
448. For example, VOCs (hazardous under RCRA and the Clean Water Act), asbestos containing building materials, and lead (hazardous under the Clean Air Act). *See also supra* (text accompanying notes 31-39 (discussing the toxicity of VOCs found in household refuse), *supra* note 429 (citing several household products that are RCRA hazardous wastes).
449. *See* Bulk Distrib. Centers, Inc. v. Monsanto Co., 589 F. Supp. 1437, 1445 (S.D. Fla. 1984) (emphasizing that CERCLA must be interpreted in such a manner so as to avoid conflicting results).

now held that an operative exclusion in one definitional reference section of a statute does not imply a general congressional intent to exempt that substance from CERCLA regulation.[444] The presence at a site of any quantity or concentration of a hazardous substance included in any of the statutes referenced by CERCLA's definition section therefore triggers CERCLA liability.[445]

The *Eagle-Picher* court adopted the EPA's argument that any hazardous *substance*, even though contained within a statutorily exempted *compound*, still subjects the material containing that hazardous substance to CERCLA regulation.[446] Similarly, another court has noted that if trace amounts of chemicals designated as toxic under the Clean Water Act are present, these chemicals are "hazardous substances" under CERCLA, regardless of whether they are regulated or exempted by RCRA.[447] In essence, the EPA has successfully asserted that any element of a hazardous substance is sufficient to trigger CERCLA liability, notwithstanding that element's exclusion from regulation under other statutes. Section 101(14) is considered an additive section: Any designation of a substance as hazardous subordinates an exclusion of that same substance contained in another definitional reference.

C. *Implications for Municipal Solid Waste*

Many components of MSW are hazardous under the Clean Air Act, the Clean Water Act, and the Toxic Substances Control Act.[448] The EPA should be held to a consistent interpretation of its enforcement position. Because the RCRA *statutory* exclusions of fly ash, mining wastes, and coal tar do not transfer to CERCLA, the RCRA *regulatory* exclusion for MSW should not contradict CERCLA's statutory intent.[449] The litigation position of the EPA with respect to the

former issue should dispose of the latter.

1. *CERCLA's Independent Basis for Regulating MSW*

By its own terms, CERCLA can include MSW without reference to RCRA or to any of its sister definitional references. As an alternative category to "hazardous substances," CERCLA's designation of those materials eligible for NPL site remediation includes any "pollutant or contaminant."[450] CERCLA defines "pollutant or contaminant" to include any substance that could cause harm to the environment or to human health from almost any exposure medium.[451] CERCLA provides an independent basis for regulating pollutants or contaminants.

As the court recognized in *Eagle-Picher*, the EPA's power to regulate a "pollutant or contaminant" is separate and independent from its power to regulate hazardous substances.[452] The exemption of a substance from the category of hazardous substances does not, therefore, diminish the EPA's ability under CERCLA to regulate pollutants or contaminants.[453] Unless expressly excluded from the definition of "pollutant or contaminant," a hazardous substance may not be excluded from the sweep of this definition.[454] MSW and its constituent elements, therefore, may not be excluded from this definition.

The consequences of this distinction are important in sculpting the contours of liability. The EPA is legally incorrect in exempting MSW from CERCLA liability at private Superfund sites. Moreover, even if the EPA's position were legally tenable, it would not be factually supported given the reality of MSW collection, typically commingling commercial and residential waste as explained below. The EPA's RCRA exclusion applies only to "household waste," and this definition does not include waste collected from commercial establishments.[455]

MSW collection practices are seldom so discreet that the entire waste stream consists of pure "household waste." Waste collection practices in many communities create a mix of household, commercial, and non-household wastes.[456] Small communities may commingle household waste with other waste at trash transfer stations, and there is no guarantee that the trash actually arriving at the MSW disposal facility will fall entirely within the definition of "household waste."[457] Some municipalities allow commercial haulers to mix commercial waste with household MSW before its final disposal.[458] Municipalities may contract with private firms for the collection, transport, and disposal of their "household waste," and the private hauler may commingle "household waste" collected in one community with a broad array of waste from other communities or from commercial clients. Once the wastes are commingled and brought to a landfill, none of the entire amalgam can be considered "household waste."

Additionally, CERCLA does not require that a material be a hazardous substance at the time it is deposited in a landfill in order for liability to attach. CERCLA speaks of hazardous substances in the present tense.[459] If a substance at a site becomes hazardous at any time, it is subject to a CERCLA remediation action. Evidence indicates that various chemicals typically found in MSW, under anaerobic conditions present in landfills, are transformed to daughter compounds.[460] Although the release of the original material may not pose a risk to human health or to the environment, the daughter compound can be considered a "hazardous substance" as defined by the EPA.

2. *The EPA's Enforcement Position*

With respect to MSW, the EPA takes an arbitrary and inconsistent enforcement position. If it furthers the purpose of prosecution, the EPA will alter its general position of exempting MSW from CERCLA's liability provisions. A number of communities have

450. 42 U.S.C. § 9605 (Supp. IV 1986).

451. According to the statute, "Pollutant or contaminant"

> includes any element, substance, compound, or mixture, including disease-causing agents, which after release into the environment and upon exposure, ingestion, inhalation, or assimilation into any organism, either directly from the environment or indirectly by ingestion through food chains, will or may reasonably be anticipated to cause death, disease, behavioral abnormalities, cancer, genetic mutation, physiological malfunctions (including malfunctions in reproduction), or physical deformations, in such organisms or their offspring.

42 U.S.C. § 9601(33) (Supp. IV 1986).

452. Eagle-Picher Indus., Inc. v. EPA, 759 F.2d 922, 926 n.4, 931 (D.C. Cir. 1985).

453. Under CERCLA section 107, the owner of a facility is not liable for the cleanup of a released "pollutant or contaminant," while an owner is liable for the cleanup of a released "hazardous substance." 42 U.S.C. § 9607 (1982 & Supp. IV 1986). The court in *Eagle-Picher* reasoned that it would be illogical for Congress to exempt a substance from the latter definition, only to include it in the former. *Eagle-Picher*, 759 F.2d at 932.

454. In *Eagle-Picher* the court held that exemptions from the definition of "hazardous substance" could not be read into the definitions for exemptions from "pollutant or contaminant." *Eagle-Picher*, 759 F.2d at 932.

455. *See* 40 C.F.R. § 261.4(b)(1) (1988).

456. For example, in Massachusetts MSW collection of residential waste, because the routing is geographically determined, will include the occasional "mom and pop" commercial establishment existing as a nonconforming use within a residential zone. It will also often include "city waste," generated by city hall or other government offices. Collection of either of these types of waste renders the entire municipal waste stream outside RCRA's definition of "household waste."

457. *Cf.* BUREAU OF SOLID WASTE DISPOSAL, COMMONWEALTH OF MASS., SOLID WASTE RESOURCE RECOVERY FOR HAMPSHIRE COUNTY 3-3 to 3-7 (June 1986) (unpublished report prepared by Hayden/Wegman Consulting Engineers) (discussing the mechanics of design and operation of transfer/transport waste stations).

458. The author, in his work with municipalities confronting this problem, finds it not uncommon for a community to allow commercial haulers, for a fee, to mix commercial waste into MSW before it is transported to cogeneration facilities or landfilled.

459. *See* 42 U.S.C. § 9601(14) (Supp. IV 1986).

460. *See supra* text accompanying notes 51-54.

therefore instituted household hazardous waste collection programs in an effort to extract hazardous waste from the MSW stream.[461] By virtue of the EPA's regulation exempting "household waste,"[462] collection program sponsors are exempt from RCRA regulation, but only if the collected waste is not commingled with any other commercial or industrial waste designated as hazardous.[463]

The EPA cannot, however, exempt these collection program sponsors from CERCLA's liability provisions.[464] An internal EPA memorandum states that neither RCRA's small quantity generator exemption[465] nor its "household waste" exemption apply when determining liability under CERCLA.[466] The EPA has concluded that potential CERCLA liability attaches "regardless of whether the material was picked up as part of a community's routine trash collection service or was gathered as part of a special collection day program."[467]

These internal EPA policy guidelines clearly elucidate a legal position that would subject generators, transporters, and owners of disposal sites of MSW containing *any* hazardous substances to liability under CERCLA. As the EPA posits: "[W]ith respect to household hazardous waste, such waste would clearly qualify as a 'hazardous substance' if it contains any substance listed in Table 302.4 of 40 CFR Part 302."[468]

Internally, the EPA goes beyond the *Eagle-Picher* holding[469] and administratively answers a question that the courts have yet to reach. Under this internal interpretation of CERCLA, all MSW is hazardous unless it is deliberately and effectively purged of all hazardous substances. Even the best organized household hazardous waste collection efforts have only a minimal impact on siphoning hazardous substances from a community's household waste stream.[470] Under the EPA's internal view, all MSW carries with it the potential for CERCLA liability.

467. *Id* at 2.
468. *Id* The substances listed in Table 302.4 are those deemed hazardous by the EPA pursuant to its regulatory authority under 42 U S C § 9602(a) (Supp IV 1986) *See* 40 C.F.R. § 302.4 (1988).
469. *See supra* notes 432-41 and accompanying text.
470. Grants for these purposes are awarded under section 8001 of RCRA, 42 U S C. § 6981 (1982). There are 530 such programs in 32 states, which achieve about one percent local participation. 17 Env't Rep. (BNA) 1254-55 (Nov 28, 1986). Some programs achieve significantly less than one percent participation These programs cost $2 $9 per pound of hazardous waste collected—an expensive price. *EPA Says Household Waste Collection Efforts Provide Benefits but Have Low Participation*, 17 Env't Rep (BNA) 1222 23 (Nov 21, 1986); *see* HOUSEHOLD HAZARDOUS WASTE SURVEY, *supra* note 30, at 7 1 to 7 6

In light of this internal enforcement position, the EPA's failure to prosecute municipal generators of MSW is confounding. In isolated instances the EPA has even provided written assurances that it will not prosecute, under CERCLA, nonprofit sponsors of household hazardous waste collection efforts,[471] although as a general policy the EPA does not pledge in advance that it will take no action against one who handles hazardous substances.[472]

In at least one situation, the EPA took the position that MSW does impose CERCLA liability. In an affidavit Dr. Kirk Brown, an EPA consultant, testified that numerous toxic chemicals discovered at the private multiple-source Flemington Landfill in North Carolina were "typical of those found in leachate of municipal solid waste landfills . . . [and that] municipal solid waste could have been the sole source of or contributed to the contamination found in the groundwater downgradient from the Flemington Landfill."[473] Although twenty percent of NPL sites are municipal-only landfills,[474] the EPA does not generally interpret its jurisdiction to allow it to prosecute MSW generators or dumpers at private Superfund sites.

In view of the EPA's position in other cases, and in view of the contrary judicial determinations of this issue, the EPA's exemption for MSW is legally inconsistent. There is simply no dispute that MSW qualifies as a solid waste and, as a matter of course, that EPA pleads its authority under both RCRA section 7003 and CERCLA section 106 when initiating Superfund cleanups.[475] Therefore, MSW should be routinely included in Superfund prosecutions, under any one of several legal authorities.

Congress recently amended CERCLA to reinforce equitable considerations regarding PRPs. The 1986 Superfund amendments officially sanction discretionary settlement "as promptly as possible"

471. *See, e g*, Letter from Michael DeLand, EPA Region I Administrator, to Dana Duxbury, League of Women Voters (May 4, 1984) (declining to take action against Massachusetts communities which might accidentally release hazardous substances during their own clean-up efforts) (copy on file at the *George Washington Law Review*).
472. *See* Memorandum from Courtney M. Price, Assistant Administrator for Enforcement and Compliance Monitoring, EPA, (Nov. 16, 1984) (copy on file at the *George Washington Law Review*)
473. Affidavit of Dr. Kirk W. Brown (Sept. 29, 1985) at 3-4, United States v. Waste Indus , Inc., 16 Envtl L. Rep. (Envtl L. Inst) 20,501 (E D N.C 1985) (No 80-4 CIV-7) (copy on file at the *George Washington Law Review*) These toxic chemicals included: benzene, 1,2-trans dichloroethylene, methylene chloride, tetrachloroethylene, tetrahydrofuran, trichloroethylene, vinyl chloride, cadmium, copper, lead, mercury, nickel, and zinc *See supra* note 414.
474 *See supra* note 70 and accompanying text
475 RCRA § 7003, 42 U S C § 6973 (1982 & Supp IV 1986), has been interpreted to impose no liability on generators no longer related to a threatening site. United States v A & F Materials Co , 578 F Supp 1249, 1258 59 (S D Ill 1984), United States v Wade 546 F Supp 785, 788 92 (E D Pa 1982) CERCLA § 106, 42 U S C. § 9606 (1982 & Supp IV 1986) has been interpreted more broadly *See* United States v South Carolina Recycling & Disposal, Inc , 653 F Supp 984, 996 (D S C 1984)

between the EPA and "de minimus" generators at Superfund sites.[476] In return for early settlement, often before completion of the RI/FS and usually at a premium price over a pro rata share,[477] de minimis PRPs that settle receive a complete release from liability (and possibly a covenant not to sue) as site remediation is undertaken.[478] Although the new legislation does not define what constitutes a de minimis PRP, the statute requires that the toxic substances contributed by a de minimis PRP must be "minimal in comparison to other hazardous substances at the facility."[479]

This new statutory emphasis on including de minimis PRPs in prosecution and settlement makes it easier for the EPA to include all parties associated with hazardous waste disposal in contribution and resolution. There is now an official mechanism by which a de minimis PRP can extricate itself from the enforcement action at an early stage, although de minimis contributors do not escape responsibility. Despite the mounting technical evidence that any party who contributes MSW at a Superfund site is a PRP, the EPA's enforcement position has not reflected this status.

476. SARA § 122(a), 42 U.S.C. § 9622(g) (Supp. IV 1986). The settlement policy in section 122 seeks in general to avoid unnecessary delays and excessive transaction costs, and in particular recognizes that "[a]llowing minor responsible parties to cash out . . . avoids the imposition of unnecessary negotiation or litigation costs on such parties," in addition to streamlining negotiations. H.R. REP. No. 253 (III), 99th Cong., 1st Sess. 32 (1985), *reprinted in* 5 U.S. CODE CONG. & ADMIN. NEWS 3038, 3055 (1986) [hereinafter HOUSE JUDICIARY REPORT].

In addition, these provisions explicitly contemplate de minimis settlements at an early stage of a Superfund proceeding. New subsection 122(g)(3) requires the Administrator of the EPA to reach settlements in these cases as soon as the necessary information is available to establish the party's de minimis status. It is the clear intention of Congress that such settlements should be expedited and that every effort be made to reach them at the earliest possible moment. Section 122(g) contemplates that site conditions do not have to be known or allowed for in a de minimis settlement. Congress contemplated that a de minimis settlement may take place before completion of an RI/FS. *Id.* at 30-32, *reprinted in* 5 U.S. CODE CONG. & ADMIN. NEWS at 3055-57.

477. *See* 42 U.S.C. § 9622(g) (Supp. IV 1986). There is no clear statutory directive as to how much of a premium should be paid by de minimis PRPs to settle early in litigation, while other largers PRPs remain. Some of this premium reflects saved transaction and legal expenses. *See* Butler, DeSmidt & Brooks, *Sue or Settle? A Method for Evaluating Superfund Settlement Proposals*, 7 Chemical & Radioactive Waste Litigation Rep. 785, 795 (1984).

478. Section 122(g)(2) expressly authorizes final releases or "covenants not to sue" for any PRP that has entered into a de minimis settlement under section 122(g). 42 U.S.C. § 9622(g)(2) (Supp. IV 1986). Although section 122(f)(6), which applies to covenants not to sue generally, provides that most covenants not to sue must have a reopener for future liabilities arising out of unknown conditions, de minimis settlements under section 122(g) are expressly exempted from this requirement. *Id.* § 9622(f)(6). Section 122(b)(4) of SARA allows a de minimis settlement to be entered using either a consent decree or an administrative order. 42 U.S.C. § 9622(b)(4) (1982 & Supp. IV 1986).

479. *Id.* § 9622. "De minimis" is a relative term. The House Judiciary Committee Report reiterates that, to be eligible for settlement under section 122(g), a party's contribution in terms of volume and toxic effect "must be minimal compared to the other substances at the facility." HOUSE JUDICIARY REPORT, *supra* note 476, at 31, *reprinted in* 5 U.S. CODE CONG. & ADMIN. NEWS at 3054. The term "toxic effect" is also relative. *Cf.* EPA Draft Hazardous Waste Settlement Policy at 3, 50 Fed. Reg. 5034, 5037 (1985) (stating that volumetric allocation is appropriate where "the properties of all wastes at the site are relatively equal").

IX. Conclusion and Policy Implications

A. Municipalities: Special Treatment?

It is a policy choice as to whom Congress allocates the responsibility for the cleanup of hazardous wastes in America. One can agree or disagree with the congressional decision to cast the net of legal responsibility over all parties associated in any direct manner with the generation, transportation, and disposal of any hazardous substance, whether public or private. Yet the place to wage that debate is in the Congress. If Congress wishes to exempt municipalities from liability for the cleanup of hazardous substances originating in the MSW stream, it can do so explicitly.

Congress, however, has not explicitly exempted municipalities from liability. There appears to be no congressional concern for special treatment of MSW in the legislative history of CERCLA. The EPA practice of exempting municipalities from CERCLA enforcement at private, mixed waste sites is fashioned from whole cloth at the agency. The exemption appears to be cut from practical expediency and convenience rather than along legal lines.

The EPA's discretionary action allowing this "exemption" does not comport with either legal or factual realities. Legally, neither the small quantity generator nor the "household waste" exceptions in RCRA apply to CERCLA liability for MSW, and factually, most MSW would not fall within the "household waste" exclusion. The 1986 Superfund Amendments underscore the intended liability of public and de minimis contributors of hazardous substances.

Although CERCLA does not provide legal distinctions for different entities, there may be some factual and legal distinctions for municipalities. There are 39,000 units of independent local government; more than three quarters have fewer than 3,000 citizens and more than half have fewer than 1,000 citizens. The resultant distinctions include:

(1) Municipalities may have even greater difficulty than businesses in obtaining any type of insurance coverage;

(2) Some role of municipalities in the handling of MSW is inevitable, and MSW disposal is a required public activity in most communities;

(3) The ability of municipalities to quickly respond to a settlement option is constrained by the democratic decisionmaking processes employed in town government;

(4) The transaction costs of participating in the Superfund settlement process can be substantial for small PRPs, including municipalities;

(5) The role of the state, vis-a-vis municipalities, may make some

municipalities more practically akin to a subsidiary parent relationship.

Without considering the merits of such distinctions, the EPA assumes contradictory prosecutorial positions on a case by case basis. The EPA's prosecution decisions shift billions of dollars of cleanup responsibilities to parties that CERCLA designates as jointly and severally liable, thereby entirely excusing some municipalities and imposing their cleanup share on private parties. The Charles George Superfund site saga illustrates the potential inequity of such discretion.

The policy repercussions of this reality loom large. A shift of hundreds of millions of dollars of PRP liability onto the municipal sector affects all parties. For many municipalities these costs would translate directly into higher property tax levies. As a result, current property taxpayers would indemnify PRP municipalities for past waste disposal practices, raising intergenerational equity issues. In some situations, this burden on the municipal fisc would spill over into requests for state assistance. Yet some states are already having difficulty in expeditiously raising their minimum ten percent matching share required on expenditures from the federal Superfund.

B. A Choice of Rules

There is a fundamental policy choice that is made when allocating Superfund liability: Should an environmental decision rule or an ability-to-pay equity rule apply to the liability allocation process? The distinction is between treating differently situated entities similarly or differently at Superfund sites. With an environmental decision rule, Superfund liability is allocated based on some measure of cleanup responsibility, without consideration of PRP size or ability to pay. Such a rule causes any PRP to internalize the actual risk of liability in its waste handling and management practices.

In contrast, an ability-to-pay rule distinguishes ultimate Superfund responsibility based on the identity of the PRP, rather than on the proportionate share of remediation costs or damages. Although offering the potential for a more flexibly crafted settlement policy, this procedure does not result in an efficient allocation of responsibility in a market-driven economy. The EPA's Interim Settlement Policy discusses settlement criteria that would accommodate either an environmental decision or an ability-to-pay rule. Through which of these alternative templates one cuts its Superfund liability is a fundamentally distinct policy choice.

With an environmental decision rule, private PRPs would experience some relief from the percentage share of cleanup responsibility they bear. In most situations, this shifting of costs to the public sector will not in itself affect aggregate PRP funding of remediation activities. In most, but not all, situations, PRPs as a group are financially capable of making remediation payments if they so choose.

The issue is one of equity. At mixed sites, an equitable allocation of cleanup costs among private and public PRPs may actually promote private PRP willingness to contribute to cleanup settlements. The perception of equity in the allocation of removal and remediation costs influences the perceived legitimacy of the CERCLA liability scheme. A perception of fairness will promote private PRP settlement, in lieu of litigation.

CERCLA and its legislative history provide no guidance as to how to apportion liability among generators, transporters, owners, and operators, as well as among contributors of different hazardous substances at contaminated sites.[480] The allocation of liability is ad hoc and inconsistent from site to site. The practical difficulty in making such allocations motivated the Congress in 1986 to empower the EPA to become more involved in apportioning liability for voluntary settlements.[481]

As some scholars note, the common law doctrine of "restorative restitution" should inform the ultimate allocation of responsibility for CERCLA remediation.[482] This restitution would allow a party who bears a remediation responsibility disproportionate to traditional concepts of common law liability to initiate an action for costs prior to restoration of the property.[483] This doctrine is akin to an action to abate a public nuisance.[484] Economically, this doctrine also internalizes costs on the parties most capable of controlling their own hazardous substance contributions.

The application of an environmental decision rule is the only rule of prosecution and settlement that can earn support as fair and equitable from all quarters. The magnitude of potential cleanup liability, coupled with the severity of the "joint and several" rule when not fairly applied, demand a prosecutorial posture that is regarded as fair. For the long-term viability of hazardous waste remediation, this reputation for fairness is essential to spur prompt, voluntary

480. 42 U.S.C. § 9607(a) (Supp. IV 1986).

481. The EPA is empowered by SARA to issue nonbinding preliminary allocations of responsibility and to aid PRPs in reaching an allocation of responsibility for purposes of settlement. 42 U.S.C. § 9622(e)(3) (Supp. IV 1986). These nonbinding allocations are inadmissible as evidence. *Id.*

482. *See, e.g.*, Baker & Markoll, *By Products Liability: Using Common Law Private Actions to Clean Up Hazardous Waste Sites*, 10 HARV. ENVTL. L. REV. 99, 100 (1986) (providing an excellent treatment of common law doctrine applicable to hazardous waste remediation).

483. Baker and Markoll note that "restoration restitution" is consistent with the rationale employed in *Spur Industries v. Del E. Webb Development Co.*, 108 Ariz. 178, 494 P.2d 700 (1972). Baker & Markoll, *supra* note 482, at 119. The authors further explain that *Spur* turns on concepts of unjust enrichment to the prevailing party for the abatement of the other party's nuisance. Therefore, the question of abatement of a nuisance or a hazard is distinct from the question of who bears the cost of such abatement. *Id.* at 120. Restitutionary remedies allow this latter question to be addressed separately from the former CERCLA imposed responsibilities. *Id.* at 121.

484. *Id.* at 120.

remediation. To the degree that this rule burdens public PRPs, its application can be tempered to reduce municipal liability.

C. *Available Options to Assist Municipalities*

There are several policy options in Superfund settlement situations that would reduce the aggregate amount of municipal liability.

(1) Mixed funding from the Superfund could be used to pay some or all of the cost attributable to municipalities;

(2) Municipalities could be treated as de minimis generators, perhaps by netting only the hazardous substances in the MSW;

(3) Municipalities could be credited for efforts at household hazardous waste collection recycling or other waste minimization activities;

(4) To the degree that a municipality could be deemed a transporter rather than a generator of waste, its liability could be characterized as contingent or secondary;

(5) Municipalities could be allocated only the marginal cost of site remediation attributable to the presence of MSW (either on a volumetric, toxicity, or combined basis);

(6) In certain circumstances a Superfund site could be geographically isolated to segregate the locus of MSW disposal from hazardous waste disposal and liability apportioned;

(7) A credit policy could be implemented to reduce the liability of municipalities handling MSW on a nonprofit basis;

(8) Municipalities could be exempted from contributing to "orphan" shares of liability allocated by the EPA under the theory of joint liability when certain PRPs cannot be located or are bankrupt; or

(9) Because of the large volume of MSW and its relatively low toxicity by volume, only certain costs (such as site capping costs but not groundwater remediation costs) could be allocated to municipal PRPs.

It should be noted that these options do not eliminate nor excuse municipal PRP liability but merely reduce the aggregate amount of liability. As a practical matter, the EPA does not appear anxious to employ the limited resources of the Superfund to bail out municipalities in the status of either owner-operator or generator-transporter. Municipalities in the status of owner-operator must comply with site closure plans under RCRA.[485] For the EPA to use the Superfund to accomplish cleanup of municipally owned and operated landfills is equivalent to use of the Superfund as a grant to subsidize RCRA site closure.

It is unlikely that many municipalities, especially the smallest ones, will voluntarily negotiate a settlement of their PRP liability. For financial or administrative reasons, or both, before contributing

485. 42 U.S.C. § 6903(15) (1982) (defining persons to whom RCRA applies to include any "state, municipality, . . . political subdivision of a state, or any interstate body."); *see also supra* text accompanying note 69

toward remediation, municipalities will await an order to pay resulting from a contribution action instituted by the EPA or other PRPs. However, in return for settlement, the EPA can offer municipalities a release from subsequent suits by private PRPs.[486]

As in many environmental matters, when there is scientific and factual uncertainty, the allocation of the burden of proof is critical: Should plaintiffs retain the burden of demonstrating that each municipality disposed of hazardous substances in MSW at each site? Should there be a presumption that MSW contains hazardous substances, which shifts the burden to a municipality to rebut this presumption? Would such a presumption flow from generalized national data, or should it be site-specific based on sampling? Whichever side—the public sector or private sector PRPs—ultimately inherits the final burden of proof is likely to lose in any legal confrontation.

A correct allocation of CERCLA remediation responsibility among private and public parties may ultimately call for state or even federal direct or indirect subsidies of municipal liabilities. Already there is cost sharing among governmental entities when the Superfund is tapped to perform cleanup activities.[487] Although subsidizing municipal CERCLA liability by state or federal governmental entities is a somewhat different proposition, the placement of financial responsibility on those who generate the hazardous substances, even when payment is made from tax revenues (where MSW contributes the hazardous substances), is the economically and legally correct demarcation point for any discussion of waste policy.

At the very least, this argues for inclusion of municipal PRPs at the initial stages of Superfund site negotiation, prior to litigation. The EPA should issue section 104 notice letters and requests for information to municipal PRPs, whether their status is that of owner, operator, generator, or transporter. This will bring municipal PRPs into the process at an early stage, promote the sharing of information, broaden the debate among parties, and promote a perception of equity in enforcement. In turn, this will heighten the chance of cleanup settlement. Refusing to bring in municipalities retards the realization of these goals.

MSW poses a massive long-term challenge. The dominant current practice of landfilling waste is shortsighted and is the precursor to future problems. Within the legislated rubric of American haz-

186. SARA § 122(g), 42 U.S.C. § 9622(g) (Supp. IV 1986), *see supra* note 478

187. 42 U.S.C. § 9601(c)(3)(C) (Supp. IV 1986). The states pay either a 10% share of remedial action costs borne by the fund or a 50% or greater share of remedial action costs where the state or its political subdivision owned the disposal site during the period of disposal. *See supra* notes 168-69 and accompanying text

arde waste law, however, municipalities stand in the same shoes as p[illegible] entities. Selective and inconsistent enforcement practices in enforcing CERCLA's provisions portends a major legal struggle for the allocation of cleanup responsibility. This allocation issue will dominate the future course of Superfund navigation through the legal straits.

might have been helpful, but in a case this complex the information falling within the broad purview of federal discovery is almost without limit. In this light it is hard to fault the district court for placing limitations on discovery. Given the circumstances of this case, we see no abuse of discretion either in its discovery orders or its decision rejecting the appellants' Rule 56(f) motions.

D. *Expert Opinion*

A final contested issue common to most of the claims involved in the instant case concerns the district court's evaluation of the scientific expert opinion of Dr. Kirk W. Brown, a Professor of Soil and Crop Sciences at Texas A & M University. The coalitions relied on Dr. Brown's affidavit as crucial evidence in opposing the appellees' summary judgment motions. Before discussing the district court's assessment of Dr. Brown's affidavit, a brief review of the contents of the affidavit is necessary.

1. *Expert's Credentials and Methodology*

Dr. Brown holds a masters degree from Cornell University and a doctorate in agronomy from the University of Nebraska. He has written more than 150 scholarly, scientific articles and a book dealing with the disposal and treatment of hazardous waste substances. His professional qualifications make him an expert witness, and the district court so found. *See Murtha II*, 815 F.Supp. at 543.

Dr. Brown submitted an affidavit in support of the coalitions' position that appellees were potentially responsible parties at both landfill sites. In preparing this sworn statement, he reviewed numerous reports including, most significantly, six reports relating to the Laurel Park landfill and three reports discussing the Beacon Heights landfill.[5] After examining these reports, the expert was of the opinion that "there [were] CERCLA hazardous substances present in each and every leachate sample from these landfills." Dr. Brown did not personally visit the landfills or dig up any shovelfuls of waste, but he was not required to do so.

He studied EPA reports concerning municipal and industrial landfills in the United States and he set forth the types of hazardous substances found in waste streams generated by households, commercial establishments, institutions, and industries. He used these reports to generate lists of the wastes and CERCLA hazardous substances routinely discarded by typical households, commercial establishments, institutions, and industries during the time period relevant to this case. After comparing the concentrations of hazardous substances in the leachates from the two landfills with the concentrations generally found in municipal solid waste landfills in the United States, he concluded, in his expert opinion, that the waste streams disposed of in the two landfills were similar to the landfills he had studied and that they contained CERCLA hazardous substances.

Further, Dr. Brown read the statements that the various appellees made in their deposition testimony and read other documents relevant to the kind of waste disposed of by each appellee. His comments varied for each appellee. Based on the available information, he meticulously linked the types of wastes, including identification of specific products discarded by each defendant, with specific CERCLA hazardous substances. His analysis relied on a series of studies and reports that showed which known CERCLA hazardous substances are in specific waste products. This allowed him to correlate the specific wastes disposed of by each appellee to specific hazardous substances.

For example, when a party admitted to disposing of tire products, Dr. Brown explained which hazardous substances are found in normal tire products. Although he could not swear with absolute certainty that the tire products disposed by a specific appellee were similar to normal tire products, such absolute certainty is not required to oppose successfully a summary judgment motion, rather, at the summary judgment stage, the trial judge must decide only whether a reasonable jury could find liability by a preponderance of the evidence. Further, when the appellees failed to submit any evidence to distinguish the products of which they disposed from those addressed by Dr. Brown in his affidavit, Dr. Brown's probabilistic evidence stands largely uncontradicted. Moreover, each and every type of product disposed of need not contain hazardous substances. Any amount of such substances is sufficient to create liability.

5. Some appellees claimed that Brown never studied the two landfills involved in this litigation or that he failed to investigate the landfill wastes. This is patently wrong. Particularly mendacious is the implicit claim by Manafort Brothers, Inc., Eric Arsan Refuse, NRS Carting, and Zollo Drums that none of the studies used by Dr. Brown dealt with the relevant landfills. This contention is wholly contradicted by the record.

2. *Admissibility of Brown Affidavit*

Although the district court agreed that Dr. Brown was an expert, and that his evidence could be admissible against certain parties, it apparently did not place much weight on the affidavit. It ruled that the expert's sworn statement was not controlling for non-municipal generators, *id.* at 544, and that it could not be applied to the municipal generators because no adequate foundation for its acceptance had been laid. *Murtha III*, 840 F.Supp. at 189. More specifically, the district court added, Dr. Brown's "references to facts, without specification, in various documents relied on, are insufficient to make his opinions relevant." *Id.* It therefore rejected the affidavit as lacking "probative merit" because it did not rely on "direct evidence." *Id.* at 184. In addition, the court expressly weighed the affidavit against the backdrop of the EPA Municipal Policy, according to which the EPA made certain enforcement decisions. *Id.* at 188.

[16, 17] Our view of this affidavit and its probative worth differs dramatically from that of the district court. This is partly because it is difficult for us to imagine an expert with more experience and knowledge in the hazardous substances field than Dr. Brown, and partly because we find his affidavit to be carefully researched, detailed, and directly relevant to this case. As will become clear when we consider each appellee's case individually, we think the trial court assessed the weight of conflicting proof, in effect substituting its judgment for that of the jury. *See In Re Joint Eastern & Southern Dist. Asbestos Litig.*, 52 F.3d 1124, 1133 (2d Cir.1995) (applying the rule prohibiting such a practice). Environmental science, like epidemiology, "is ill-suited to lead a factfinder toward definitive answers, dealing as it does in statistical probabilities." *Id.* Here there was only one expert opinion before the court, and the court was obliged not to ignore it. Because Dr. Brown reviewed nine studies concerning the subject landfills, his affidavit was laid on a proper foundation.

[18–22] When deciding a motion for summary judgment, only admissible evidence may be considered. *Tamarin v. Adam Caterers, Inc.*, 13 F.3d 51, 53 (2d Cir.1993). Where scientific knowledge will assist a trier of fact to determine an issue of fact, an expert witness "may testify ... in the form of an opinion or otherwise." Fed.R.Evid. 702. Summary evidence is admissible when the underlying documents are admissible and are made available to the adverse party. *Tamarin*, 13 F.3d at 53. Here, where the reports used by Dr. Brown are of the sort ordinarily relied on by experts in forming opinions within their field of expertise, the reports need not be admissible at trial, *see* Fed.R.Evid. 703, and need not actually be attached to the affidavit to satisfy Fed. R.Civ.P. 56(e). *See Iacobelli Constr., Inc. v. County of Monroe*, 32 F.3d 19, 25 (2d Cir. 1994). An expert's testimony, in order to be admissible under Rule 705, need not detail all the facts and data underlying his opinion in order to present that opinion. *See* Fed. R.Evid. 705; *Ambrosini v. Labarraque*, 966 F.2d 1464, 1469 (D.C.Cir.1992). At any rate, the Brown affidavit does provide the specific facts required by Rule 56(e), *see id.* at 1470, when he explains which specific hazardous substances are found in each waste disposed of by each appellee.

[23] Nor is the Brown affidavit "junk science" of the sort that should be rejected under *Daubert v. Merrell Dow Pharmaceuticals, Inc.*, 509 U.S. 579, 113 S.Ct. 2786, 125 L.Ed.2d 469 (1993). Dr. Brown relied on the methodology and data typically used and accepted in these sorts of cases, *see Iacobelli*, 32 F.3d at 25, and his testimony would therefore be admissible under *Daubert*, [illegible] U.S. at 592–95, 113 S.Ct. at 2796–98. Moreover, if

cates dispute the cost figure contending that it assumes that EV costs will never come down.

OES Releases New Draft of Uniform Hazmat Inventory Form

The Office of Emergency Services (OES) has released a revised draft of regulations establishing a uniform format to be used by all businesses reporting their hazardous materials inventories under the state's Hazardous Materials Release Response Plans and Inventory Act (Health and Safety Code Chapter 6.95; sections 25500 et. seq.). The uniform format is mandated by 1992 legislation (AB 1524 -Killea) designed to eliminate industry complaints about inconsistent requirements imposed by the various local agencies who administer the Act on a local level. The new form will take the place of all local forms and is also designed to meet reporting requirements under the federal Emergency Planning and Community Right-to-Know Act [42 USC section 11002]. However the format contemplates that local agencies can require additional information beyond the minimum required under the state and federal acts.

A previous draft of the regulations was released for public comment in December (CEI December 31, 1994). The latest draft makes a number of changes based on comments received on that draft. The most significant of these is the addition of an addendum designed to meet the requirements of section 80.103(c) of the Uniform Fire Code. This will discharge OES's obligation under another piece of legislation (AB 1777-O'Connell). OES is still required to comply with a third piece of legislation (AB 1451-Umberg) which requires adoption of a uniform format for meeting emergency planning requirements under Chapter 6.95 (see CEI Special Report, August 31, 1994).

In addition to working on the above regulations, OES has begun the development of a computer program that may be used when reporting the inventory information electronically. The database was created using Filemaker Pro and will be available for Apple and DOS computer systems. If all goes as planned, the software will be distributed free of charge, sometime in 1996, by OES to any administering agency or business that is interested.

Although it has not scheduled a public hearing on the latest draft, OES will consider comments on the entire package through August 25. For information contact Tracey Vardas or Terry Keel at (916) 262-1750.

Expansion of Dump is a Taking by County

In a decision which may chill local governments throughout the state, a San Diego County Superior Court judge has ruled that the expansion of the San Marcos landfill in 1990 constituted inverse condemnation of nearby residential properties. The decision by Judge Morgan Lester resulted from a lawsuit filed by approximately 20 neighbors of the landfill who contended that noise, odors, and heavy equipment comings and goings associated with the expansion, substantially reduced the value of their properties. Although a jury still has to determine the amount of the loss, estimates by experts for both sides range from $1.2 to $3.5 million.

The County began expansion of the landfill in 1990 after a hard fought battle with the neighbors who ultimately lost an appellate court decision on whether the County had violated the California Environmental Quality Act. The landfill had been operated since 1978 and was originally scheduled to be closed when it reached an elevation of 750 feet. Because the County was unable to find another location for a new landfill, it obtained a permit from the San Diego Regional Water Board allowing it to expand both vertically and horizontally. In late 1990 the County began holding meetings with the neighbors which included offers to appraise their properties. As part of these discussions the County indicated it might be willing to purchase the properties. According to Judge Lester these meetings, combined with the November 13 certification of the EIR for the expansion, created a "pall" over the properties. The result was that those residents that wanted to sell had trouble even finding brokers with whom to list their properties and those that did list them were forced to reduce their asking price. The judge noted one specific instance where a potential buyer discovered the possible impacts of the expansion and decreased his purchase price offer by $35,000.

Aside from the market value damage, Judge Lester found that during the actual expansion the resident plaintiffs were subjected to adverse physical impacts which created "another separate basis for inverse condemnation." These included odors of garbage and mulching operations, excessive dust coming onto the properties, the noise coming from the heavy equipment involved in constructing the actual expansion, and the noise and dust created from about 350 trucks making daily trips to dump garbage. The judge specifically singled out the beeping noise made by the earth moving and other heavy equipment as it worked on the expansion. Because of all of this the residents "use and enjoyment" of their properties was substantially interfered with. The County argued that one of the plaintiffs should be treated separately since he did not live on his property but used it as an avocado grove. However judge Lester found that the owner was on the property often and therefore suffered the same loss of use as the others.

The County also argued that the taking was "temporary" because the City of San Marcos has revoked the land use permit for the dump effective in March of 1997. Judge Lester however noted that the work associated with closing the landfill after that date, is likely to drag on well after the year 2000 and thus the taking should be considered permanent.

A jury trial to determine the amount of the plaintiffs' losses is currently scheduled to begin on September 5. The assessed value of all of the parcels involved is about $10 million. Experts for the plaintiffs have estimated that the

continued on next page

San Diego Dump

continued from previous page

dump caused a decline in value of about 35% while experts for the County put it at 12%.

Paul McKee et al. v. County of San Diego, #N59587-1 (San Diego County Superior Court).

First Expedited Cleanup Application Approved

As we discussed in our last issue, a site selection committee has approved the application of the Santa Fe Railroad to have the first site remediated under the states new Expedited Remedial Action Program (ERAP)—also known as the SB 923 program after the legislation that authorized it. The ERAP program is a pilot project under which 30 sites will be selected to go through an expedited remediation process which relies on a number of variations to the state's normal contaminated property cleanup process—including the possibility of site-cleanup standards that are less stringent than would otherwise be required and are tailored to the proposed use of the property. The program is administered by the Department of Toxic Substances Control.

The Santa Fe site is located in Vernon California and consists of a 10 acre parcel which was used as a truck terminal from May 1955 until March 1990. It is currently vacant. Santa Fe does not actually yet own the site. It is acquiring it through an eminent domain proceeding. The company has received a court order under that proceeding allowing it to take possession of the site which, under DTSC's SB 923 regulations, give it the requisite "indicia of ownership" to allow it to apply for the program. While it is able to gain the benefits of the program, as a "bonafide prospective purchaser", Santa Fe is not considered a "responsible person" for purposes of the Department's apportionment of liability for cleanup costs. However the company is required to agree with DTSC to pay any cleanup costs which are not otherwise covered by responsible parties or by the trust fund set up under SB 923. DTSC's Megan Cambridge indicates that this means more than likely that Santa Fe will end up paying for the cleanup.

Past remediation activities at the site included the removal of two 10,000-gallon underground fuel tanks and a 1,000-gallon waste oil tank in 1991. As a result of the underground tanks and a gasoline spill onsite, 2,600 cubic yards of hydrocarbon contaminated soil had to be excavated. The excavated soil was treated onsite using bioremediation and vapor extraction systems. The treated soil was then backfilled onsite. Those remediation activities were overseen and approved by the City of Vernon's Health and Environmental Control Department.

In order to have its application accepted, Santa Fe was required to prepare and get DTSC staff approval of a Preliminary Endangerment Assessment (PEA). The site is covered with asphalt that is underlain by an average of seven feet of fill material comprised, at least in part, of foundry sand containing elevated levels of lead and copper. The PEA concluded that the fill material does not pose a threat to groundwater and that the site overall does not pose a significant risk to public health and the environment; a necessary finding for the SB 923 process. DTSC concurred with this conclusion but determined that further remedial action is required. This will include removal of onsite structures and construction of a low permeable cap extending across the entire site. Santa Fe intends to incorporate the site into an existing intermodal facility located in the immediate area.

The second of the two applications that have been filed, involving the California Steel (CSI) site in Fontana, is scheduled to be considered by the site-selection committee in early August. DTSC's Megan Cambridge told CEI that these are the only two formal applications received, although several more are allegedly being prepared. Applications for the program are still being accepted.

For further information contact Ms. Cambridge at (916) 255-3727.

Waste Board Seeks to Clarify Authority Over Recycling Facilities

In addition to debating its jurisdiction over contaminated soil (discussed in our last issue), the Integrated Waste Management Board at its June 28th meeting also dealt with a sticky, even more controversial jurisdictional issue—its authority to regulate facilities engaged exclusively or primarily in recycling activities. The authority of the Board and local governments over recycling operations has been a much debated issue in the last few years leading to one Supreme Court case (the Rancho Mirage Decision). As we indicated last issue the Board's legal staff has taken the position that the Rancho Mirage decision should not limit the Board's authority to regulate a particular material. Nevertheless the Board action on June 28th attempts to deal with its authority over recycling facilities without really answering the question dealt with in Rancho Mirage: where does the definition of "solid waste" begin and end.

As was the case with contaminated soil the Board approved a staff position paper. The staff's position is that jurisdiction over recycling facilities should depend on whether they are handling "source-separated recycles with a minimal amount of residual." If a facility can meet this test it is outside Board jurisdiction. The Board's position is based on the fact that the definition of "solid waste facility" includes transfer and processing stations [Pub. Resources Code §40194]. Public Resources Code §40200 then excludes from the definition of transfer or processing facility anyone whose "principal function" is to receive or process wastes that have been "separated for reuse." Under this definition most recyclers will be outside of the Board's regulation. These include drop-off centers, buy-back centers, curbside collection processing facilities, community recycling centers, commercial paper recyclers, and scrap metal recyclers. This assumes that these facilities have procedures in-place that

COMMUNITY PROFITS FROM ITS WASTE
Phoenix Gazette (PG) - MONDAY, August 29, 1994
By: Victor Dricks, THE PHOENIX GAZETTE
Edition: Final Section: Metro Page: B1
Word Count: 697

TEXT:
It takes 11 weeks to accomplish, but the residents of Pinetop-Lakeside can do something with sewage sludge and household garbage that few communities can.

They can turn waste into compost, which they sell.

"We were looking for an environmentally friendly way of disposing of all of our solid and liquid waste, and I think we've come up with it," said John Snyder, sanitation district manager for the Pinetop-Lakeside community on the Mogollon Rim.

Several years ago, Snyder said, his community was searching for a way to comply with federal waste disposal standards. Stricter regulations have prompted municipalities from San Diego to Milwaukee to build expensive landfills with plastic liners capable of storing hazardous waste without leakage.

"We wanted to do something different," Snyder said. "It really didn't make much sense for us to build a landfill to handle the waste from 5,000 households."

Pinetop-Lakeside could have trucked its waste to a landfill in Joseph City, 80 miles to the northeast.

Instead, Snyder contacted Bedminster Bioconversion Corp. of Cherry Hill, N.J., which developed a technique of turning sewage sludge and household garbage into compost. The company's first plant was built in Big Sandy, Texas, in 1972. Pinetop-Lakeside opened its plant in 1991 and a third recycling facility began operating in Sevier County, Tenn., in 1992. Several others are planned or under construction across the country.

For municipalities trying to keep their heads above a rising tide of [illegible] waste, converting trash into money.

"The best part is we can sell our compost to a company in Taylor for $7.85 per cubic meter, which generates about $15,000 a year in revenues for us," Snyder said.

The Taylor company uses the compost in potting soil.

At that rate, it costs Pinetop-Lakeside about $24 per ton to dispose of its waste, half the cost of using a landfill. But Snyder said there are advantages to recycling that cannot be measured strictly in terms of dollars.

"The project enjoys the support of the community because it takes two waste streams and combines them to produce a desired product," Snyder said.

"This is the wave of the future," said Nelson Widell, Bedminster executive vice president. "For decades, it's been part of our frontier mentality that we thought we could just throw everything away. But we can't continue to do that. We've been despoiling the environment and wasting valuable resources."

Seventy percent of the solid waste that goes into Bedminster's plant is converted into compost. Only 30 percent of the community's waste has to be put in a landfill, Widell said.

And how do you make a trash cocktail?

Just combine 10 tons of household garbage -- metal cans, coffee grounds, glass bottles, plastic containers, food packaging, table scraps and all -- with five tons of liquid sewage. Place this in a chambered steel vessel 70 feet long and 10 feet in diameter that spins slowly, and let time -- and microbes -- go to work.

The high carbon content of household garbage and the high nitrogen content of sewage sludge make composting possible. Special conditions created in the vessel accelerate the conversion of solid, organic wastes to humus, the primary nutrient of topsoil.

"We can do in a few weeks what would take months or years for nature to accomplish," Snyder said. "We just load our garbage into a giant steel vessel that rests on its side and pump our sewage sludge in, making sure to keep a 2-to-1 ratio.

"After three days we run this stuff through a sieve, which removes anything larger than an inch and a quarter, load the stuff back into the steel cylinder and repeat the process."

The compost then is formed into large piles set inside in an enclosed building, heated and aerated for 11 weeks while microbes continue the conversion process.

And how does this stuff smell?

Not too bad. Snyder swears only a "light, earthy aroma" is detectable from the compost because the facility in which this process occurs is well-ventilated and air within the building is screened with special biofilters.

CAPTION:
Garbage is loaded into a steel chamber in Pinetop-Lakeside on way to becoming compost.

FINANCES OF INCINERATION AND LANDFILL FACILITIES

Richard Gilbert
Consultant in Urban Issues, 15 Borden Street, Toronto, Ontario M5S 2M8.
Tel. (416) 923-8839. Fax (416) 923-6531. E-mail 72114.611@compuserve.com

Notes for a presentation to a forum organized by the Recycling Council of Ontario on Energy from Waste Incineration, Sheraton Centre, Toronto, May 4, 1995

THE ENVIRONMENT IS MORE IMPORTANT THAN FINANCES

1. Environmental protection, not finances, should normally be the main consideration in the selection of waste disposal facilities.

2. Finances should be an important consideration only when high costs make the use of an environmentally superior method impracticable or when the greater investment can be better applied elsewhere.

MUCH WASTE WILL REQUIRE DISPOSAL

3. Even with aggressive waste diversion—well beyond present provincial targets—some 8,000 tonnes of Greater Toronto Area (GTA) waste will require disposal each day during the first few decades of the next century.

4. Of this amount, about 80 per cent (i.e., more than 6,000 tonnes a day) will be suitable for incineration.

5. Incinerating the residual waste that can be incinerated, and landfilling the remainder, will reduce needed landfill capacity by about 70 per cent, i.e., from 8,000 tonnes to 2,400 tonnes a day.

6. Moreover, the 2,400 tonnes of waste a day to be landfilled will be essentially inert and thus environmentally benign.

THE COSTS OF LANDFILL AND INCINERATION ARE SIMILAR

7. Table 1 on Page 2 provides comparisons between the costs of GTA landfill sites, actual and proposed, and two operating incinerators, one large and one relatively small. Costs have been made comparable, as explained in the Notes on Page 3.

8. A reasonable conclusion from Table 1 is that the net costs of landfill and incinerator facilities are similar, mostly in the range of $50 to $75 per tonne of waste received. Landfill and incineration both permit substantial economies of scale.

9. After 20 years (when debts are paid off and the landfill sites are full), incineration becomes much cheaper. If well maintained and updated, an incinerator can last for a further 20 years or more with much reduced capital costs and resulting lower net costs.

10. If less waste is received than anticipated both landfill and incinerator facilities can encounter problems with debt retirement. The solution is proper sizing of facilities.

11. Waste feed for incinerators can be supplemented with waste reclaimed from closed landfill sites that are considered hazardous.

12. Table 2 on Page 4 summarizes the key differences between landfill and incinerator facilities from a financial perspective.

TABLE 1. COMPARISON OF LANDFILL AND INCINERATOR FACILITIES

(superscript numbers refer to the numbered notes on the next page)

	Landfill facilities[1]				Incinerators[2]	
	Halton site	Durham site	Peel site	York-Metro site	Fairfax	Lancaster
Status	In operation	Proposed	Proposed	Proposed	In operation	In operation

Surcharges per tonne[11]	38.00	n.a.	n.a.	n.a.	20.00	12.69

NOTES

[1] The four operating and proposed landfill sites are in the Greater Toronto Area. The Halton site is owned and operated by the Region of Halton. The Durham, Peel, and York-Metro sites are those proposed by the Ontario government's Interim Waste Authority (IWA). Information about the Halton site was provided by the Region. Information about the IWA sites was adapted from the source indicated in Note 12 below, which was based in part on the *Environment Protection Act* documentation filed by the IWA. How the IWA sites will be owned and operated has not yet been determined.

[2] The Fairfax incinerator is in Fairfax County, Virginia. It was constructed and is owned and operated by Ogden Martin Systems Inc. and comprises four 680-tonne-per day furnaces. The Lancaster incinerator is in Lancaster County, Pennsylvania. It is owned by the Lancaster County Solid Waste Management Authority and was constructed and is managed under contract by Ogden Martin Systems Inc.. It has three 364-tonne-per-day furnaces. Both incinerators have dry flue gas scrubbers and fabric filter baghouses. All information given here is in the public domain and represents actual current operations; sources were Ogden Martin and the respective County administrations. Dollar values are in Canadian dollars. Conversions from U.S. currency and measures are as follows: US$1.00 = C$1.37; 1 hectare = 2.47 acres; 1 tonne = 1.102 short tons.

[3] The current annualized amount of waste being received is shown for the Halton facility. It is much less than the anticipated amount of 200,000 tonnes on account of waste export (see the source in Note 12). Hence the high costs per tonne for this facility. The expected amounts of waste are given for the three proposed IWA facilities although, as explained in the source in Note 12, these amounts may not be realized, thus raising costs per tonne. Rated capacities are given for the two incinerators; actual waste receipts are close to rated values.

[4] Daily waste receipts were estimated on the basis of 275 days a year of landfill operation and 365 days a year of incinerator operation.

[5] Project costs include all capital costs incurred or required up to one year after the commissioning date. Subsequent capital costs, including provision for post-closure care, are considered here as operating costs. Project costs for the three proposed IWA sites are those projected and explained in the source in Note 12 rather than those given by the IWA, whose projections did not take many essential items into account. Project costs are given in dollars of the years of construction—in 1993 dollars for the IWA's proposed sites. Other monetary items in this table are in 1995 dollars.

[6] Yearly average figures are given for energy revenues. Actual contracts with generating utilities can be complex and involve both fixed capacity payments and payments for power supplied that vary according to need. Revenue per megawatt-hour in Ontario could be lower than the lower value noted here.

[7] These amounts represent the principal and interest charges in respect of debt incurred to meet project costs (defined in Note 5 above).

[8] All facility costs not represented in the previous row are represented in this row, including operating, maintenance, administration, ash disposal, post-closure costs, and many others.

[9] Landfill gas or energy generated using landfill gas can be a source of revenue for landfill facility operators. Net revenues from such energy sales are more likely to be in the order of $1.50 per tonne of current waste received rather than the $25-$50 per tonne received from sales of electric power generated by energy-from-waste incinerators. Revenue data for incinerators shown here includes revenue from sales of reclaimed ferrous materials and other revenue; revenue from energy sales is generally well over 90 per cent of total revenue. In both cases considered here, 90 per cent of energy revenues accrue to the respective County authority, 10 per cent to the plant operator.

[10] Net costs per tonne comprise capital, operating, and other costs per tonne less revenue per tonne. The net costs shown for the IWA's sites are 3.0 per cent higher than the estimates given in the source in Note 12 because 1995 dollars are used here rather than 1993 dollars.

[11] Surcharges per tonne comprise disposal fees per tonne less net costs per tonne. The surcharges are used for a variety of purposes including management of transfer stations, subsidization of other disposal facilities and 3Rs programs, and public education about 3Rs.

TABLE 2. GENERALIZED FINANCIAL COMPARISONS OF LANDFILL AND INCINERATOR FACILITIES

ITEM	INCINERATION VS. LANDFILL	COMMENTS
Site acquisition costs	●●●	Landfill facilities require about 10 times as much land as incinerators per tonne handled, even more if necessary buffer zones are included.
Construction costs	□□	The other capital costs of incinerators are two to three times higher per tonne than those of landfill facilities.
Operating costs	□	Gross operating costs of incinerators are generally higher per tonne than those of landfill facilities.
Revenues	●●●	Incinerator revenues (where there is energy recovery) are generally 20 times or more per tonne of waste handled than energy revenues from landfill facilities.
Net costs (first 20 years)	—	Where there is energy recovery, the net costs per tonne of landfill and incinerator facilities are similar for the first 20 years of operation (i.e., during the lifetimes of the landfill facilities and the period of retirement of the debts incurred for project costs).
Net costs after 20 years	●●●	If well maintained and updated, incinerators can be used for a further 20 years or more, with much reduced capital costs and resulting lower net costs. Landfill facilities, on the other hand, become a liability when they are full.

EDISON ADVANCED INTEGRATED RECYCLING
(AIR)
PROJECT DESCRIPTION

Introduction

The Advanced Integrated Recycling (AIR) of refuse is a highly advanced technology which may provide an environmentally beneficial process for combatting growing problems associated with solid waste disposal. Through the AIR process, refuse is reduced by at least 90% of its original volume, recyclables are reclaimed, and a clean synthesis gas is produced with no air emissions. Landfill volume reduction may be further enhanced by development of products which utilize the ash produced in the AIR gasifier process. This technology is projected to be commercially demonstrated by 1996.

The purpose of the AIR Project is to test and commercially demonstrate this technology to convert refuse into a clean fuel gas. The AIR Project was conceived to help provide a solution to refuse disposal problems in sensitive air quality areas where incineration is not acceptable.

Background - The Environmental Problem

Solid waste disposal is approaching crisis levels across the country including Southern California. Approximately 50,000 tons of refuse are being generated each day in Los Angeles County alone. Within Edison's service territory the quantity of refuse is 70,000 tons per day. Landfill capacity close to the source of waste generation is being exhausted. New capacity is difficult to site due to public opposition and regulatory constraints. These factors are exerting enormous pressure to reduce landfill usage and are forcing landfills to be located in remote areas necessitating significant transportation expense.

Partial solutions to this waste disposal problem come in the form of source reduction (generating less waste), recycling, and possible hauling of refuse by rail to remote desert landfills. Landfill volume reduction achievable through source reduction and recycling is mandated by AB 939 beginning in 1995. Other options include waste-to-energy technologies.

Commercialized Waste-To-Energy Alternatives

Commercial burning of refuse by existing combustion processes is not a desirable technology in the South Coast Air Basin. These processes result in large NOx emissions which exceed limitations for power plants set by the South Coast Air Quality Management District (SCAQMD). Only two existing waste-to-energy facilities are currently operating in Southern California under earlier

SCAQMD regulations. No emission control technology currently exists that will allow direct refuse combustion to meet the new SCAQMD standards being imposed on Edison power plants. In addition, the Environmental Protection Agency (EPA) has begun tightening emission regulations nationwide. This trend will continue and will place extreme restrictions on refuse incineration. The alternative to direct burning of refuse is gasification of "refuse derived fuels" (RDF). It represents a potential solution to the refuse disposal vs. air quality dilemma. Gas produced from refuse gasification can be cleaned prior to combustion resulting in very low emissions, similar to natural gas. The most promising technology for RDF gasification is called fluidized bed gasification. It has been used commercially for wood waste gasification and tested at a pilot scale using refuse. Because of its efficiency and its capability to gasify a wide variety of waste products, this technology was selected for the AIR Project.

AIR Process Description

The Advanced Integrated Recycling Demonstration Project (AIR) will utilize 150 tons per day of RDF. Considering California's minimum goal of recycling 25 percent of the waste stream, at least 200 tons per day of municipal solid waste will be processed at a Material Recovery Facility (MRF) to produce the required RDF tonnage. The refuse will be processed mechanically to remove recyclable materials for return to the marketplace. The refuse will pass through a trommel which is a large cylindrical drum with holes sized to separate out the heavy fraction of the waste stream which contains metals, glass, rocks, dirt, etc. The lighter material remains in the trommel and is further processed to remove more metals and other inert materials. Finally, the remaining non-recyclable refuse is shredded, to below 2 inches is size. This final product is a "refuse derived fuel" (RDF) (Figure 1). The RDF is placed in large transfer trailers and delivered to the project site. The RDF is delivered inside a receiving building which is equipped with odor and dust control. Here the RDF is stored until needed for the gasifier. The building will hold enough RDF for up to two days of gasifier operation.

The RDF is then loaded onto a conveyor by a front end loader. The conveyor delivers the RDF to a live bottom storage hopper which will hold enough RDF for three hours of operation. The RDF is automatically removed from the bottom of the hopper and delivered into an air tight feed screw which meters the RDF into the bed of the gasifier.

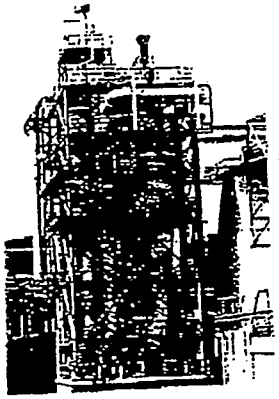
The gasifier is a vertically standing cylindrical vessel, partially filled with sand. The sand is fluidized by air through ports in the bottom of the gasifier which make the sand appear to boil. As RDF enters the gasifier it is immediately

entrained with the sand and rises with the sand in the gasifier. The RDF reacts with the hot sand, driving off the volitiles to form a gas. The gas, sand and RDF particles rise in the gasifier to the top where they exit and pass through a cyclone. The cyclone separates the solids from the gas returning the sand and ungasified RDF back to the lower portion of the gasifier (Figure 2). The process continues until the carbon in the RDF is converted to a gas, leaving a light, dry ash. The ash remains with the gas as it exits the cyclone and is finally separated from the gas in a second cyclone. Heavy ash particles which contain more inerts than the fly ash settle to the bottom of the gasifier and are removed.

The gas which has exited the second cyclone where fly ash was removed passes through a heat exchanger to cool the gas. The cooled gas then enters a wet scrubber where impurities are washed from the gas. Any condensable oils and tars which precipitate out at this point are recycled back to the gasifier where they are converted into a gas. The gas finally enters sulphur removal equipment which cleans the gas of sulphur. The gas is now cleaned to a level virtually as clean as natural gas, the cleanest fossil fuel in widespread use.

The scrubber wash water is recycled back to the scrubber after the impurities are concentrated and separated. This concentrated scrubber waste water is processed to remove contaminants. The remaining purified water is conveyed to the generating station waste water retention basin for ultimate discharge to an industrial sewer along with other plant wastes.

It is planned to test several methods of using the ash directly as an aggregate in asphaltic or portland cement concrete. In this case, long term leaching tests will be required to verify that this method of use meets EPA guidelines for prevention of release of potentially hazardous substances. Other methods of treatment may also be explored. One such method involves placing the ash in an electric glass making furnace where high temperatures melt the ash into a vitreous or glassy inert material. This vitrified material can be recycled into an aggregate for road base.



Summary

The 200 tons per day of refuse will be processed to yield 150 tons of RDF which will be gasified to produce 50 million Btu's per hour of a clean gas containing about 115 Btu's per cubic foot. Natural gas, by comparison, contains about 1000 Btu's per cubic foot. This low Btu gas made from refuse can be combusted in a utility boiler, industrial boiler, or internal combustion engine. In these applications it will displace 50 million Btu's per hour of natural gas, with no

new emissions. When converted to electricity, this gas will generate 5 Mw, which will provide enough energy for 5000 households.

6/29/93

AIR — The Advanced Integrated Recycling Project will utilize 200 tons per day of household and commercial refuse. The refuse will be processed mechanically to remove recyclable materials for return to the marketplace. The remaining refuse will be shredded into a refuse-derived fuel (RDF). The RDF will be delivered into a gasifier where it will be converted into gas and then passed through a scrubber to remove contaminants. The clean gas will replace natural gas in the existing Edison electric generating station. This will be the first facility in the world to convert refuse to energy without air emissions.

Advanced Integrated Recycling — AIR

Edison firmly believes that gasification technology is the best environmental and economic solution to municipal waste disposal in Southern California. Recycling and waste reduction are both required to diminish the problem, yet there will always be some waste requiring ultimate disposal. The waste gasification concept enhances recycling while converting the remainder of the waste into a clean fuel gas.

Edison began development of the first commercial scale municipal waste gasification facility in the world in 1991. Construction could begin in 1994, with operation of the demonstration phase to begin in 1995. The demonstration project will be known as the AIR (Advanced Integrated Recycling) Project.

Environmental Benefits

Fluidized bed gasification will provide an environmentally acceptable solution to other waste disposal alternatives in Southern California. The use of the product gas in electrical generation equipment will not increase air emissions. If a commercial gasification project can be sited adjacent to a utility boiler, the low-Btu gas can be used to displace natural gas and result in overall NO_x reduction.

This demonstration will provide valuable technical and environmental information to air quality management agencies, the waste disposal industry and electric utilities. It is designed to demonstrate that gasification of waste is a superior alternative to combustion in sensitive air quality areas, and to landfilling in heavily populated areas.

How It Works

The demonstration will involve the processing of 200 tons per day of municipal waste (trash) to remove recyclables, leaving only the organic portion of the waste stream called refuse-derived fuel (RDF). The RDF is fed into a fluidized bed gasifier which contains hot sand. The hot sand reacts with the RDF to form a gas. The product gas is cooled and cleaned to remove any contaminants carried over from the gasification process. The clean gas then can be burned in a power plant boiler, producing 5 MW, or in an industrial boiler. The product gas, because of its lower Btu content, burns cleaner than natural gas, thus reducing emissions.

The scrubber waste water is cleaned to remove the contaminants and is delivered to the power plant waste water system. The ash from the gasifier can be stabilized for use as a recyclable product.

The gasifier technology is modular, ideal for small to large communities and does not require any smoke stack since nothing is released into the atmosphere from the gasification process.

FACILITY OVERSIGHT: SEMINAR SPOTLIGHTS CURRENT, PENDING EPA REGULATIONS AFFECTING LANDFILLS

Landfill managers, who already must comply with an array of federal rules, will face more regulations in the next few years, a panel of experts told participants at Waste Expo '97.

EPA Office of Water official John Tinger led off the session with a review of the agency's rulemaking on effluent limitations from landfills. Tinger highlighted the proposal that EPA unveiled April 21 (SWR, April 24, p. 1). "The effluent limitations are based on specific technology, but don't require the use of specific technology. How a landfill achieves the standard is up to the manager," he said.

Tinger also noted that EPA considered requiring some technologies, such as reverse osmosis, "but the costs of reverse osmosis didn't justify the benefits."

Douglas Cloud, an attorney with the Atlanta, Ga., firm of Alston & Bird LLP, followed with an assessment of recent regulatory development in the Clean Air Act (CAA). He began by discussing the two major permits of concern to landfill managers: New Source Performance Standards (Title V operating permits) which deal with emissions standards, and New Source Review (NSR) construction permits.

Whether a CAA permit is required, Cloud said, depends on several factors, including:

- The types and quantities of air emissions expected from the facility;

- The planned activity (constructing a new landfill or modifying an operating landfill);

- Whether the facility is located in a CAA attainment area (an area that meets national ambient air quality standards) or CAA nonattainment area.

In building a new landfill, managers must figure out the site's potential to emit certain pollutants. "It's not what you actually emit," Cloud noted. "You have to calculate your worst-case scenario."

Similarly, landfill managers wishing to make a major modification to their facilities are required to conduct a two-step analysis. First, they must determine whether the change constitutes either "routine maintenance, repair or replacement," or an increase in hours of operation or rate of production. Landfills conducting either of these types of changes are exempt from new permit requirements. In addition, landfills installing gas or energy collection and control systems may be eligible for a pollution control project exemption.

"It's a definition by exclusion," Cloud said, noting that virtually any other change will trigger CAA requirements.

Second, facility managers must figure their "significant net emissions increase" from the modification, using a specific formula.

Finally, landfill operators must consider the type of area in which the facility operates. Environmental regulators in nonattainment areas cannot allow a new major source of pollution without offsetting reductions from another source. There is a minimum offset ration of 1:1, but state officials can demand stricter ratios from new emissions sources.

"You have companies literally buying up other businesses [that are sources of emissions] just to shut them down," Cloud said.

When asked whether a new landfill compactor could trigger CAA requirements, Cloud responded, "Routine repair and replacement is exempted. You could make a reasonable argument that just replacing a piece of equipment is not subject to NSR. But it depends on whether it will increase your emissions."

MORE REGULATIONS TO COME

Paul Cassidy, an environmental engineer with the EPA Office of Solid Waste, wrapped up the discussion with a look at several major EPA regulations in the pipeline. For example, a final rule currently being reviewed by the White House Office of Management and Budget would provide regulatory flexibility for small, dry, remote (SDR) landfills. EPA tried to exempt these facilities from ground water monitoring requirements in 1991, but a legal challenge from the Sierra Club resulted in a court decision vacating the exemption.

Congress acted in March 1996 to provide regulatory relief to SDR facilities with passage of the Land Disposal Program Flexibility Act. In response, EPA reinstated the groundwater monitoring exemption for these sites last September. A final agency rule providing additional flexibility on such requirements as daily cover is scheduled for release before October, Cassidy said.

The agency also is hammering out a final rule on financial

assurance requirements for companies and local governments on landfill closure and post-closure care. A final rule is slated for release in August.

A rule on lead-based paint debris that contractors generate will cover municipal solid-waste landfills, according to Cassidy. The EPA Office of Pollution and Prevention and Toxics will determine whether this debris can go to Subtitle D (nonhazardous) landfills, or whether it must be sent to Subtitle C (hazardous) landfills. The agency will release a proposal in the fall.

Cassidy concluded by noting that EPA had released a report on greenhouse gas emissions in April and is seeking public comments (SWR, May 8, p. 151). Contacts: John Tinger, EPA Office of Water, (202) 260-4992,; Douglas Cloud, Alston & Bird LLP, (404) 881-7894.

OFFICE OF
AIR QUALITY PLANNING
AND STANDARDS

MEMORANDUM

SUBJECT: Classification of Emissions from Landfills for NSR Applicability Purposes

FROM: John S. Seitz, Director
Office of Air Quality Planning and Standards (MD-10)

TO: Director, Air, Pesticides and Toxics Management Division, Regions I and IV
Director, Air and Waste Management Division, Region II
Director, Air, Radiation and Toxics Division, Region III
Director, Air and Radiation Division, Region V
Director, Air, Pesticides and Toxics Division, Region VI
Director, Air and Toxics Division, Regions VII, VIII, IX and X

The EPA has recently received several inquiries regarding the treatment of emissions from landfills for purposes of major NSR applicability. The specific issue raised is whether the Agency still considers landfill gas emissions which are not collected to be fugitive for NSR applicability purposes.

The EPA's NSR regulations define "fugitive emissions" to mean "those emissions which could not reasonably pass through a stack, chimney, vent, or other functionally-equivalent opening" (40 CFR 51.165(a)(1)(x)). In general, where a facility is not subject to national standards requiring collection, the technical question of whether the emissions at a particular site could "reasonably pass through a stack, chimney, vent, or other functionally-equivalent opening" is a factual determination to be

made by the permitting authority, on a case-by-case basis. In determining whether emissions could reasonably be collected (or if any emissions source could reasonably pass through a stack, etc.), "reasonableness" should be construed broadly. The existence of collection technology in use by other sources in the source category creates a presumption that collection is reasonable. Furthermore, in certain circumstances, the collection of emissions from a specific pollutant emitting activity can create a presumption that collection is reasonable for a similar pollutant-emitting activity, even if that activity is located within a different source category.

In 1987, EPA addressed whether landfill gas emissions should be considered as fugitive.[1] The Agency explained that for landfills constructed or proposed to be constructed with gas collection systems, the collected landfill gas would not qualify as fugitive. Also, the Agency understood at the time that, with some exceptions, landfills were not constructed with such gas collection systems. The EPA explained that "[t]he preamble to the 1980 NSR regulations characterizes nonfugitive emissions as '. . . emissions which would ordinarily be collected and discharged through stacks or other functionally equivalent openings'" (see 45 FR 52693, Aug. 7, 1980).[2] Based on the "understanding that landfills are not ordinarily constructed with gas collection systems," the Agency concluded that "emissions from existing or proposed landfills without gas collection systems are to be considered fugitive emissions." The Agency also made clear, however, that the applicant's decision on whether to collect emissions is not the deciding factor. Rather, it is the reviewing authority that makes the decision regarding

---

[1] See memorandum entitled "Emissions from Landfills," from Gerald A. Emison, Director, Office of Air Quality Planning and Standards, to David P. Howekamp, Director, Air Management Division, Region IX, dated October 6, 1987 (attached). It is important to note that the interpretation contained in this memorandum was only applicable to landfills.

[2] In fact, the 1980 preamble language recognized the concern that sources could avoid NSR by calling emissions fugitives, even if the source could capture those emissions. The EPA's originally-proposed definition of fugitive emissions was changed in the final 1980 regulations to "ensure that sources will not discharge as fugitive emissions those emissions which would ordinarily be collected and discharged through stacks or other functionally equivalent openings, and will eliminate disincentives for the construction of ductwork and stacks for the collection of emissions." Id.

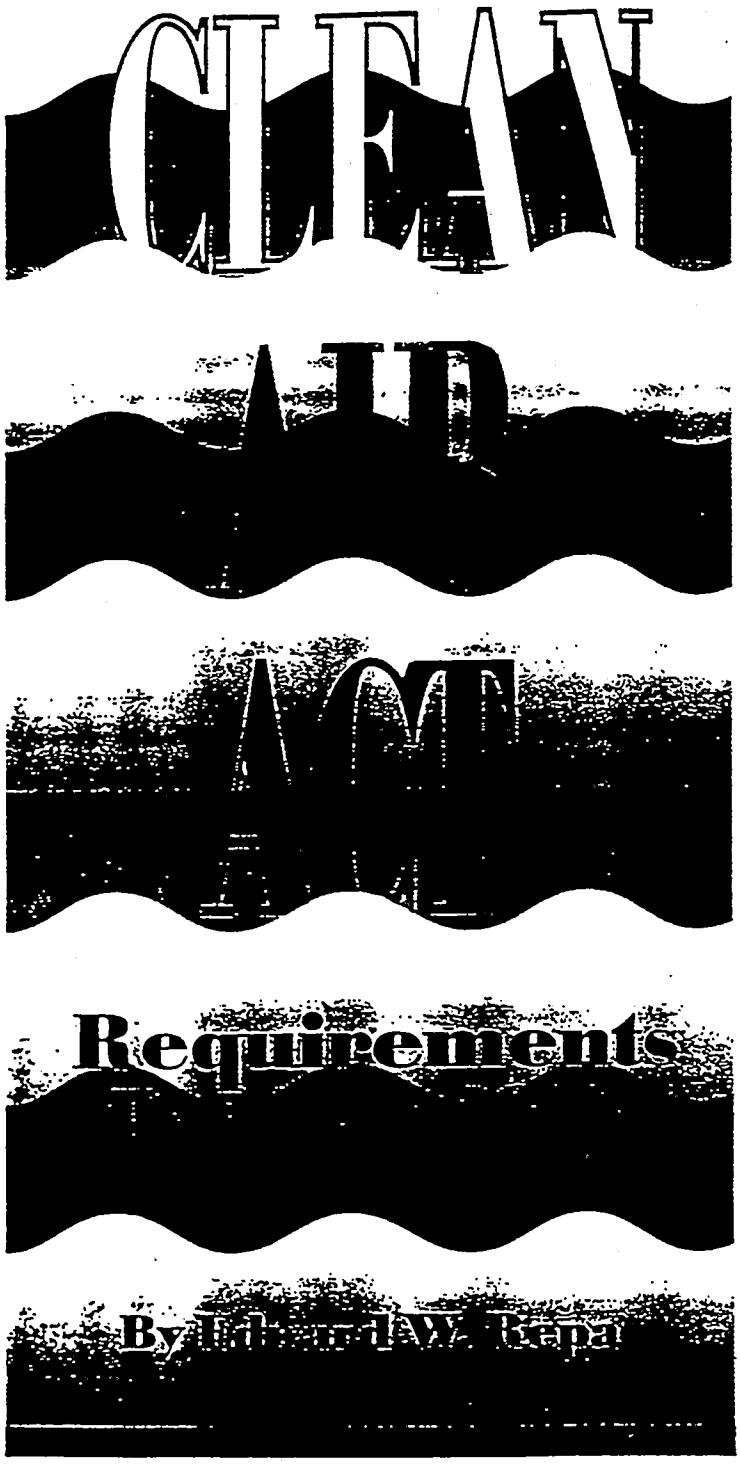
which emissions can reasonably be collected and therefore not considered fugitive.

The EPA believes its 1987 interpretation of the 1980 preamble may have been misunderstood, and in any case that its factual conclusions at that time are now outdated. Continued misunderstanding or application of this outdated view could discourage those constructing new landfills from utilizing otherwise environmentally- or economically-desirable gas collection and mitigation measures in order to avoid major NSR applicability.

Specifically with regard to landfill gas emissions, gas collection and mitigation technologies have evolved significantly since 1987, and use of these systems has become much more common. Increasingly, landfills are constructed or retrofitted with gas collection systems for purposes of energy recovery and in order to comply with State and Federal regulatory requirements designed to address public health and welfare concerns. In addition, EPA has proposed performance standards for new landfills under section 111(b) of the Clean Air Act and has proposed guidelines for existing landfills under section 111(d) that, when promulgated, will require gas collection systems for existing and new landfills that are above a certain size and gas production level (see 56 FR 24468, May 30, 1991). Under these requirements, EPA estimates that between 500 and 700 medium and large landfills will have to collect and control landfill gas. The EPA believes this proposal created a presumption at that time that the proposed gas collection systems, at a minimum, are reasonable for landfills that would be subject to such control under the proposal.

Thus, EPA believes it is no longer appropriate to conclude generally that landfill gas could not reasonably be collected at a proposed landfill project that does not include a gas collection system. The fact that a proposed landfill project does not include a collection system in its proposed design is not determinative of whether emissions from a landfill are fugitive. To quantify the amount of landfill gas which could otherwise be collected at a proposed landfill for NSR applicability purposes, the air pollution control authority should assume the use of a collection system which has been designed to maximize, to the greatest extent possible, the capture of air pollutants from the landfill.

In summary, the use of collection technology by other landfill sources, whether or not subject to EPA's proposed requirements or to State implementation plan or permit requirements, creates a presumption that collection of the emissions is reasonable at other similar sources. If such a system can reasonably be designed to collect the landfill's gas



emissions, then the emissions are not fugitive and should be considered in determining whether a major NSR permit is required.

Today's guidance is applicable to the construction of a new landfill or the expansion of an existing landfill beyond its currently-permitted capacity. To avoid any confusion regarding the applicability of major NSR to existing landfills, EPA does not plan to reconsider or recommend that States reconsider the major NSR status of any existing landfill based on the issues discussed in this memorandum. Also, nothing in this guidance voids or creates an exclusion from any otherwise applicable requirement under the Clean Air Act and the State implementation plan, including minor source review.

The Regional Offices should send this memorandum, including the attachment, to States within their jurisdiction. Questions concerning specific issues and cases should be directed to the appropriate Regional Office. Regional Office staff may contact Mr. David Solomon, Chief, New Source Review Section, at (919) 541-5375, if they have any questions.

NSR Contacts, Regions I-X and Headquarters

A number of recent and anticipated U.S. EPA actions related to the Clean Air Act (CAA) rules will have a significant effect on landfill owners and operators, requiring compliance with existing, proposed, or soon-to-be-proposed CAA requirements. This article summarizes these actions and is the first of a series of articles on CAA requirements that will appear in Waste Age *throughout the year.*

Title I of the Clean Air Act (CAA) requires states with nonattainment areas for criteria pollutants (including ozone and oxides of nitrogen [NOx], to adopt a variety of programs to bring these areas into compliance with relevant standards. One of the programs is the New Source Review (NSR) program that requires "major sources" to obtain a preconstruction permit. These permits require facilities to:

- Meet the lowest achievable emission rates (LAER);
- Obtain emission offsets (i.e., enforceable emission reductions from other operations or facilities within the project that more than offset the increase in emis-

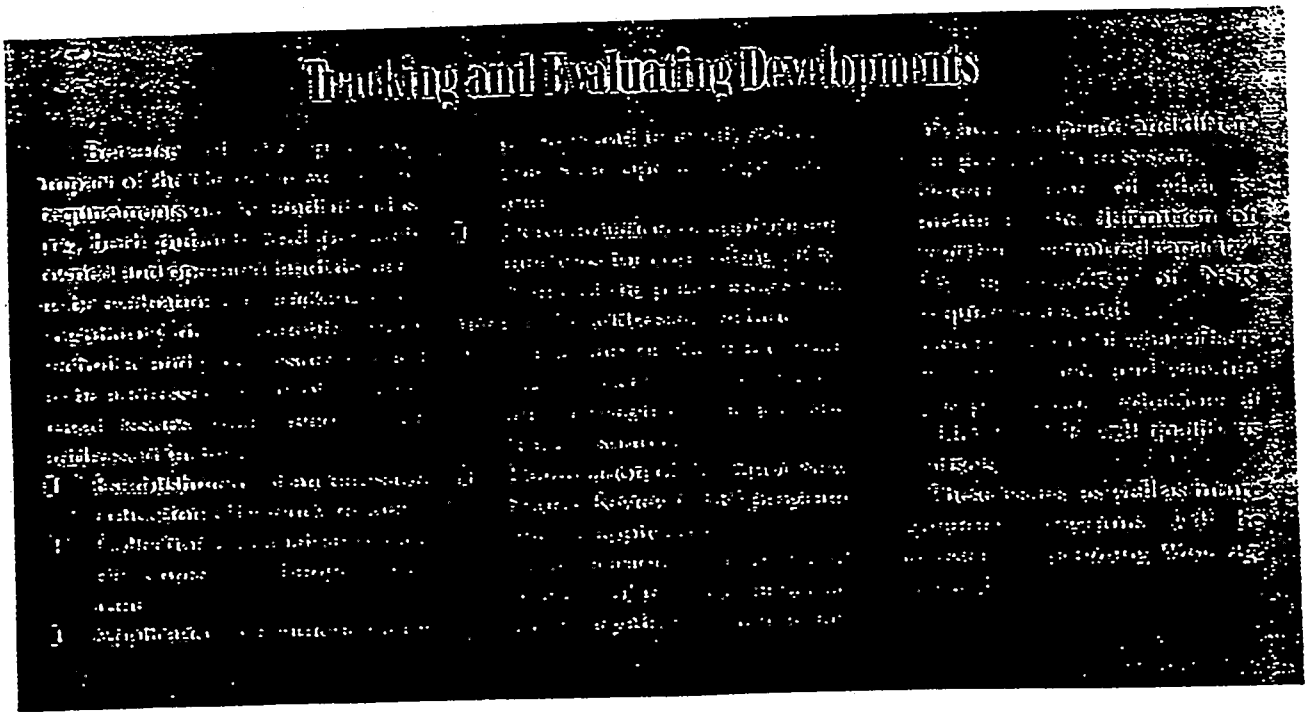
Repa is director, environmental programs, for the Environmental Industry Associations (Washington, D.C.).

sions from the proposed facility seeking the permit):

- Demonstrate that all major sources owned or operated by an applicant in the state are in compliance with CAA requirements; and
- Demonstrate that the benefits of the proposed source significantly outweigh environmental and social costs.

A new facility, or major modification to an existing facility, is considered a "major source" if its emissions, not counting fugitive emissions, exceed an applicable threshold (100 tons per year [tpy] in "marginal" and "moderate" ozone areas, 50 tpy in "serious" areas, 25 tpy in "severe" areas, and 10 tpy in "extreme" areas). Additionally, thresholds for major modifications may be lower.

A recent lawsuit filed by Ogden Martin Systems (Fairfield, N.J.), developers of municipal solid waste incinerators, against Browning-Ferris Industries' (BFI, Houston) New Morgan Landfill Co., Inc., in Pennsylvania raised legal issues regarding preconstruction air permitting for landfills. The suit claims that:



- The landfill is a "major emitting facility" because it has the potential to emit more than 50 tpy of volatile organic compounds (VOCs);
- Part D, Title I, of CAA prohibits the construction of a major VOC-emitting facility unless a permit to construct has been obtained; and
- The landfill has not obtained a permit to construct, and has constructed and begun operation in violation of CAA standards.

BFI believes that it has met all applicable permitting requirements in construction and operation of the landfill. While a court decision regarding the lawsuit has not occurred, it is important for landfill owners and operators to understand the requirements of CAA to prevent lawsuits that may or may not be justified.

New source review/1987 EPA guidance

In 1987, EPA Region IX requested guidance from EPA headquarters on the treatment of landfills under NSR (i.e., whether air emissions should be considered fugitive and therefore excluded from the calculations for the potential to emit for NSR purposes). Gerald Emison of the Office of Air Quality Planning and Standards responded to the region's request. EPA's position in 1987 was:

- Fugitive emissions are "those emissions which could not reasonably pass through [a] stack, chimney, vent, or other functionally-equivalent opening"

(40 CFR 51.165(a)(1)(x));

- Since landfills are not ordinarily constructed with gas collection systems, air emissions from existing or proposed landfills without gas collection systems are to be considered fugitive emissions and not included in the NSR applicability determination as a major source; and
- Landfill gas that was collected through some type of collection system and discharged to the atmosphere must be included in the source's potential to emit when calculating NSR applicability.

Therefore, based on this guidance, only those pollutants released from a flare, turbine, or other combustion system were to be counted toward the potential to emit as a major source.

As a result of [redacted] "rethinking" [redacted] applicability of the [redacted] Source Review (NSR) [redacted] to landfills, most larger landfills will have to consider NSR prior to construction or expansion beyond currently permitted capacity.

1994 EPA guidance

More recently, because of evolving technical, political, and regulatory issues, EPA received several inquiries regarding whether, and to what extent, EPA had changed its position since the 1987 memo. Specifically, EPA was asked whether it still considered uncollected landfill gas emissions to be fugitive for NSR applicability (i.e., guidelines established in the 1987 memo). In response, on Oct. 21, 1994, EPA issued a memorandum entitled "Classification of Emissions from Landfills for NSR Applicability Purposes." In summary, the 1994 EPA guidance memo states that:

- Because of advancements in gas collection and mitigation technologies since 1987 and the proposal of the "new source performance standards" (NSPS) for landfills in 1991 (scheduled to be promulgated in the summer of 1995), it is no longer appropriate to conclude generally that gas could not reasonably be collected at a proposed landfill project. The use of collection technology by other landfill sources—whether or not subject to EPA's proposed requirements, to an SIP [state implementation plan], or permit requirement—creates a presumption that collection of the emissions is reasonable at other similar sources.
- Gas collection systems should be assumed to be designed to maximize, to the greatest extent possible, the capture of air pollutants from the landfill for NSR applicability.
- Only those emissions from the gas collection system (i.e., nonfugitive) are considered when determining the applicability of NSR. Emissions from the landfill that are not collected by the gas control systems are still considered fugitive and are not considered for NSR applicability.
- The new guidance is applicable to the construction of a new landfill or the expansion of an existing landfill beyond its "currently permitted capacity."

As a result of EPA's "rethinking" on the applicability of NSR to landfills, most larger landfills will have to consider NSR prior to construction or expansion beyond currently permitted capacity. The definition of "currently permitted capacity" is not provided in the memorandum. In conversations with EPA, they indicated that currently permitted capacity could include all capacity covered under the original permit, even if cells have not yet been constructed.

State NSR issues

EPA's re-evaluation of this issue, however, only represents the federal interpretation of the requirements. State laws may be different and more stringent. For example, state law may require that fugitive emissions be included for NSR purposes.

Even if you do not have to proceed through major NSR, most states are required to have a minor NSR program as part of their SIP. Minor NSR refers to a variety of state programs regulating construction of new sources and modifications to existing sources that are located in nonattainment areas, but are not major sources, including exemptions from permitting. When EPA approves the state's minor NSR program as part of its plan to attain and maintain National Ambient Air Quality Standards, permits issued by the state are federally enforceable.

The advantage of having a federally enforceable per-

mit is that it can reduce the facility's potential to emit and thus affect the applicability of other CAA requirements. For example, if a facility in a non-attainment area can agree to emission limits that are below the major source threshold, it could avoid the need to obtain costly emission offsets and could obtain a five-year deferral from Title V permitting.

TABLE I

Existing Sources	Minimum MACT Floor
30 or more sources	Average emission limitations achieved by the best performing 12% of the existing sources in the category.
Fewer than 30 sources	Average emission limitations achieved by best performing five sources in the category.
New Sources	Emission control achieved by the best controlled similar source in the category.

A similar program that can ease the burden of CAA operating permits is the "synthetic minor," or federally enforceable state operating permits (FESOP), which many states have adopted. Synthetic minor permits are appropriate for sources with potential, but emissions are below the major source threshold. Sources can lower their emissions through limitations on operations or more stringent controls and thereby avoid Title V. This program may be more generally applicable to manufacturing facilities. However, FESOPs can be applied to landfill operations. A FESOP, or synthetic minor, will contain far fewer requirements than a Title V permit, and could result in a significant cost savings for a facility.

New source performance standards

After many years in development, EPA proposed new source and emission guidelines for MSW landfills under Section 129 of the CAA on May 30, 1991. EPA had been reviewing comments and additional data received on the issue, and has yet to promulgate final rules. EPA submitted a final rule to the Office of Management and Budget (OMB) for review in early fall of 1994, but retracted the rule because of OMB concerns over unfunded mandates. Apparently, EPA failed to perform this analysis prior to submittal to OMB, but has now performed the required analysis. The anticipated date for promulgation is now the summer of 1995.

The intent of the standards and guidelines is to require certain MSW landfills to control emissions to the level achievable by the "best demonstrated systems of continuous emission reduction," considering costs, non-air quality health, and environmental and energy impacts. The rules will apply to:

- New municipal solid waste (MSW) landfills for which construction, modification, or reconstruction commenced on or before May 30, 1991, or that began accepting waste on or after this date; and
- Existing MSW landfills for which construction commenced prior to May 30, 1991, and accepted waste after Nov. 8, 1987.

The NSPS will require affected landfills with design capacities of less than 1 million megagrams (Mg) or 1 million cubic meters to file a design capacity report. Affected landfills with design capacities greater than or equal to 1 million Mg or 1 million cubic meters will be required to determine their annual emissions of non-methane organic compounds (NMOC) using an air emission model developed by EPA. Emission data inputs range from default values to site-specific information collected during a field testing program. If emission levels exceed 50 Mg of NMOC per year, the landfill owner/operator will be required to install a gas collection and destruction system at the facility. EPA estimates that 8% of the existing and 10% of the new landfills (600-700 landfills) will have to install controls as a result of the rulemaking.

The emission control system installed will be based on a performance standard incorporating design flexibility. Default standards will be included for those facilities that do not elect to develop a site-specific design. Additionally, monthly monitoring of surface concentrations will be required. For a large landfill, EPA estimates that the average annual cost to the facility will be approximately $180,000 if flares are used as the combustion device.

Future requirements

Title III of CAA includes a substantially revised program to regulate hazardous air pollutants (HAPs) that may cause health or environmental effects at low concentrations. The list of HAPs contains 189 substances that are not regulated as criteria pollutants, but may be

TABLE 2

Category	Potential Annual Emissions
Attainment Areas	
Criteria Pollutant (SO_2, NOx, CO, VOC, PM10, and lead)	100 tons
Nonattainment Areas	
Carbon Monoxide	
Moderate	100 tons
Serious	50 tons
PM10	
Moderate	100 tons
Serious	70 tons
Ozone (VOCs & NOx)	
Marginal & Moderate	100 tons
Serious & Transport Regions	50 tons
Severe	25 tons
Extreme	10 tons
Air Toxics (189 hazardous air pollutants)	
One HAP	10 tons
Two or More HAPs	25 tons

regulated under other sections of CAA (e.g., VOC standards, and NSPS. These pollutants are regulated under CAA Section 112.

Title III defines a major source of HAPs as any stationary source, or group of stationary sources, located within a contiguous area that has the potential to emit 10 tons or more of any single HAP per year, or 25 tons or more of any two or more HAPs per year. The new HAP emission control program requires the installation of maximum achievable control technology (MACT), i.e., the maximum level of control achieved in practice within the industry (see Table 1).

MACT standards applicable to MSW landfills are scheduled for promulgation by Nov. 15, 2000. In order for EPA to meet this deadline, they must develop and propose the requirements at least a year in advance. A regulated source will have three years after its applicable MACT standard is promulgated to achieve compliance. However, even before the applicable MACT standard for landfills is finalized, states with an approved Title V program may impose case-by-case MACT on construction of major sources of HAPs or modifications of existing major sources. HAPs occur both in landfill gas and as a product of combustion in flares. Precise quantification of HAPs in landfill gas will be difficult. The air toxics programs count fugitive emissions as well as point-source emissions in determining whether a source is major.

CAA Title V

Title V establishes a program for issuing operating permits to all major sources (and certain other sources) of air pollutants in the U.S. These permits will incorporate in one document all applicable requirements, limitations, and conditions governing regulated air emissions. The key to determining a need for a federal operating permit is to know whether or not it is a major source.

The definition of a major source under Title V is broader than for NSR under Title I. A source is considered a major source and will need an operating permit if its potential yearly air emissions exceed those listed in Table 2.

Facilities will also need an operating permit if they are a source subject to an NSPS requiring an operating permit, acid rain provisions, or NESHAPs. However, states can grant a five-year deferral for minor sources.

Once an operating permit is required, the facility must address each and every regulated pollutant from each and every source regardless of how small the emissions. The facility must also account for all fugitive emissions. States will have the authority to set *de minimis* emissions levels for "insignificant activities" as part of their own permitting programs. Most states have included such a provision in their proposed Title V programs.

Permit application due dates vary from state to state. All covered facilities must submit their permit applications no later than one year following EPA's approval of the state's operating permit program. Most states, however, have established different time frames for different facilities. Some have relied on SIC codes while others have used geographic location to determine when permit applications are due. For example, Iowa, although its program has not yet been approved by EPA, called in all its permits on Nov. 15, 1994. Other states have yet to submit their programs to EPA for approval, while some have already received final approval. All this state activity is occurring even as EPA is revising the federal requirements for the state operating permit programs. ■

Vol. 74, No. 2, ISSN: 0013-4120

IOU, municipal to pilot methane energy recovery program.

In an unprecedented partnership between the Town of Groton and Northeast Utilities (NU), a local landfill that emits methane gas will become a research site for a new energy technology developed in Connecticut. Representatives from the town and the utility recently signed a memorandum of understanding, formalizing their intent to move forward with the project, subject to permits, approvals and tests on the landfill gas.

Methane gas is a potent greenhouse gas, and municipal solid waste in landfills is its largest man-made source. However, new technology developed in South Windsor, Conn., by International Fuel Cells can keep the methane gas from escaping into the atmosphere and convert it to electricity.

The process, which has the added benefits of converting landfill gas into less-harmful compounds and also removing its odor-causing components, takes place inside a device called a fuel cell.

"We're particularly excited about the partnership aspect of this project," said Dolores Hauber, Groton's mayor. "It's an excellent situation for the town for financial and environmental reasons."

For its 18-month duration, the project will allow the town to avoid the expense of providing a permanent flare to bum off the escaping gases at the landfill.

For NU, which has invested over $8 million in fuel cell research over the past 25 years, this agreement provides an ideal forum to test the fuel cell as an environmentally responsible and viable energy resource. The project is expected to cost NU approximately $150,000 for installation and maintenance of the cell. The equipment is valued at about $1.5 million and is owned by the federal Environmental Protection Agency.

The unit planned for installation is expected to produce approximately 140 kW of electricity, which will be Youted onto the Connecticut Light and Power Co. (CL&P) distribution system. CL&P, a subsidiary of NU, serves 1.1-million residents and commercial/industrial customers in 149 communities in Connecticut. The fuel cell could provide enough electric energy for the average use of about 100 homes during the 18-month project.

"As a responsible utility, we are working to keep our commitment to the Climate Challenge by reducing greenhouse gas emissions throughout our system. We are also working to develop new, efficient means of generating electricity at lower costs. And, finally, we are working to develop partnerships, such as this one, that will benefit people and businesses throughout our service territory and place us on the leading edge of new technology. For those reasons, this project fits beautifully with the many goals NU has set as we move toward deregulation in the electric industry," said Kerry Kuhiman, CL&P's Eastern Region vice president.

The fuel cell planned for installation was originally developed to produce 200 kW when fueled by natural gas. The test in Connecticut follows a six-month trial of the system in Los Angeles, where it was tested with a landfill gas pretreatment system in a similar situation, producing 140 kW. According to NU, the primary goal of this project is to review the gas pretreatment system for modifications that will improve the performance of the cell and lower cost of future systems of this sort.

Calculations were performed by BAI to determine the exit velocity, temperature and moisture content of the flare's exhaust gas. See Attachment 2 for these calculations.

4.2 Emissions Profile

As discussed in Section 3.3, the LFG management system is designed to accommodate 100 percent of the peak estimated LFG generation rate within the landfill. All LFG collected by the system will be routed through the enclosed ground-type flares for combustion.

In addition to the flare emissions, it is expected that there will be some fugitive LFG emissions notwithstanding the operation of the LFG management system. There are two reasons for this. First, although the system will be sized, when complete, to accommodate recovery of 100 percent of the LFG generated within the landfill, in practice LFG extraction systems are typically not 100 percent efficient; it is simply not possible, as an engineering matter, to ensure that all LFG produced by the landfill will in fact be captured by the extraction system. The collection efficiency of the LFG extraction system that will be installed at the Conestoga Landfill is expected to be within the range of 90 to 100%.

A second reason that there will be some fugitive emissions of LFG is that the extraction system must be installed in phases in conjunction with the development of the landfill. As a result, there will be areas of waste that may be producing LFG before it is possible to install extraction wells to serve those areas. For temporary periods during the installation of the extraction system, therefore, it will be technically not feasible to capture all LFG that may be produced.

Estimates of flare emissions of NO_x, CO and NMOC and contemporaneous fugitive emissions of NMOC are presented in Attachment 1. These estimates were developed by RMB utilizing LFG generation data based on the quantity of refuse in place for each phase of the landfill's development (see Attachment 3), the EMCON LFG Model, and the flare manufacturer's performance guarantees as discussed in Section 4.1. Table 1 of Attachment 1 shows the expected levels of emissions year-by-year assuming a LFG collection efficiency of 90%. Table 2 of Attachment 1 shows the expected levels of emissions year-by-year assuming a LFG collection efficiency of 100%. The actual emissions are expected to fall within the range of emissions reflected by these tables, depending on the actual LFG collection efficiency of the installed system.

GARBAGE FEES TO RISE IN GLENDALE, BUT TAXES FALL AGAIN

Lori Baker, The Arizona Republic

Sanitation fees for Glendale residential and commercial customers will increase starting Tuesday.

Residential sanitation fees will be $10.75 a month, up 25 cents from the previous rate. The commercial fees will rise an average of 3 percent.

In addition, the city's commercial recycling service fees will increase to $14.75 per month, up from $10.70.

City Manager Martin Vanacour said the reduced market value of recyclables and increased processing costs due to contamination are the reasons for the fee increase. He said the higher fees will allow the city to break even on recyclables collection.

Although other fees are increasing, the city is reducing the cost of disposal of clean loads of green and wood waste from $26.25 to $16.50 per ton.

Vanacour said the city wants to encourage customers to separate green waste from other types of refuse because that will result in airspace savings and a reduction in landfill gas production.

The new sanitation rates are part of a $301 million budget adopted by the City Council last week for fiscal year 1997-98, which begins Tuesday. Water and sewer rates will not change.

At a special council meeting at 7 p.m. Tuesday, the council is expected to set the property tax rate at $1.83 per $100 of assessed valuation, a drop of 5 cents over the rate for fiscal 1996-97. The reason for the decrease is because the city's expected boost in assessed valuation of property lessens the tax burden for individual owners because it is spread over a larger base.

This will be the third year in a row that Glendale has lowered its tax rate.

Re: Comments on the Draft Environmental Impact Report/Environmental Impact Statement (EIR/EIS) for the Proposed Elsmere Solid Waste Management Facility

Dear Mr. McDonald:

The South Coast Air Quality Management District (SCAQMD) is a regional public agency with responsibility for improving air quality in the areas within its jurisdiction, which includes Los Angeles, Orange, and Riverside counties and the western portion of San Bernardino County. In addition to adopting, implementing, and enforcing air pollution control regulations, the SCAQMD reviews California Environmental Quality Act documents prepared by other public agencies to evaluate the adequacy of the air quality analyses. The SCAQMD may provide recommendations to the lead agency for improving the air quality analyses and identifying additional feasible mitigation measures, if necessary.

The SCAQMD has reviewed the air quality section of the Draft EIR/EIS for the Elsmere Solid Waste Management Facility located in the South Coast Air Basin. Because of the size, location and duration of the proposed project, significant adverse air quality impacts for criteria pollutants are expected. Not all of the potential adverse impacts and feasible mitigation measures have been fully addressed in the Draft EIR/EIS. The mitigation measures presented in the Draft EIR/EIS should be required, not merely recommended. An enforceable mechanism for assuring implementation of all feasible mitigation measures should also be included before the project is approved. The attached staff assessment presents a more detailed discussion of the SCAQMD's review of the of the Draft EIR/EIS.

The SCAQMD comments are intended to advise the lead agency in addressing and mitigating the potential adverse air quality impacts of the project. The SCAQMD appreciates the opportunity to review the Draft EIR/EIS for the Elsmere Solid Waste Management Facility and is available to answer any questions you may have, or provide further assistance regarding air quality issues. Questions should be addressed to Terry McCall (909) 396-3107.

Sincerely,

Cindy S. Greenwald
Planning Manager
Office of Planning and Policy

EXH. 9-2

ATTACHMENT

SCAQMD ASSESSMENT OF ELSMERE SOLID WASTE MANAGEMENT FACILITY DRAFT ENVIRONMENTAL IMPACT REPORT

AIR QUALITY RULES AND REGULATIONS (Section 6.1.2)

- Page 6-7. The ambient air quality relied upon data in Table 6.1-2 is not the most current. Ambient data are available through 1994 and should used for all emission calculations (See also reference to Table 6.1-2 on page 6-17).

- Page 6-9. The EIR references the 1991 AQMP. The appropriate document to be used for reference, comparison and a determination of consistency is the latest revision to the SCAQMD AQMP which was adopted in September, 1994.

- Page 6-12. The section on the potential future SCAQMD regulations seems to overlook PM10 measures that are scheduled to be developed in 1996. This section should recognize the Federal requirements for the development of "best available control measures" (BACM) to reduce the amount of fugitive dust and corresponding PM10 emissions from a variety of sources in the district. Under the provisions of the Federal Clean Air Act, PM10 control measures must be developed by the SCAQMD that will be applicable to any land use or activity, including landfills, that have the potential to generate fugitive dust. 385.1

  The SCAQMD fugitive dust regulations will be developed as part of the State Implementation Plan (SIP) for PM10 in the South Coast Air Basin. The SIP must show the BACM PM10 measures will be applied to stationary sources that emit PM10 or PM10 precursors, including NO_x, SO_x and ROG. The federal Clean Air Act requires these measures to be in place and enforceable no later than February 1997. To this end, the SCAQMD has organized a PM10 Task Force with community leaders and industry and academia representatives in the district to assist in coordinating the development of the PM10 SIP with affected facilities. The EIR/EIS should refer to the ongoing development of PM10 measures which will likely have a impact on the proposed project.

AMBIENT AIR QUALITY (Section 6.1.3)

- Page 6-18. The discussion of the state and federal attainment status of criteria pollutants is somewhat misleading. While the district had only one exceedance of the State 1-hour CO standard in 1994, it has not been designated as "in attainment" for the CO in any respect. The district is in attainment with the NAAQS for lead and SO_2. 385.2

CONSTRUCTION EMISSIONS (Section 6.2.1)

- Page 6-26. The EIR/EIS accurately states that construction emissions exceed SCAQMD significance thresholds and are considered a significant impact. Air dispersion modeling is a very effective tool to simulate impacts associated with the transport of pollutants from the project. The broad statement that "dispersion modeling was not considered necessary to assess construction impacts" should be clarified. It is the policy of the SCAQMD to determine the project's significance based on estimates of daily emissions. Dispersion modeling is not used estimate the daily and quarterly emissions. Since the project is found to exceed the SCAQMD's significance threshold for criteria pollutants, subsequent modeling is not required for a significance determination. Due to the determination of significance, all feasible mitigation is required to reduce the construction-related emissions regardless of the results of subsequent modeling. 385.3

OPERATIONAL EMISSIONS (Section 6.2.2)

- Page 6-32. The EIR/EIS states that combustion emissions from flares would be offset by emission reduction credits available from the SCAQMD's priority reserve (SCAQMD Rule 1309.1). It should be noted that this source of offsets may not be available at the time the flares become operational. Amendments to SCAQMD Regulation XIII are scheduled for the SCAQMD Governing Board's consideration in November 1995. The proposed amendments would exclude privately-owned landfills from the essential public services that are eligible for credits from the priority reserve. Privately-owned landfills have obtained a substantial number of emission reduction credits from the SCAQMD priority reserve. The elimination of free credits for sources that operate for profit is expected to increase the availability of credits to other public-owned landfills. The EIR/EIS should be revised to discuss options available to the project proponent to obtain external offsets in the event credits are not available from the SCAQMD priority reserve. 385.4

- Pages 6-34 to 6-39. The analysis of energy impacts in Section 17.0 - Energy is based on the 1991 Draft Final AQMP. More current baseline information on the energy demands in the district can be found in the SCAQMD EIR for the 1994 AQMP (August 1994). The annual energy consumption to operate service buildings and maintenance yards for the proposed project is estimated at 75×10^6 kilowatt hours per year (page 17-3). The analyses of operational emissions in Section 6.2.2 does not appear to address criteria pollutants emissions expected to result from any additional electrical generation that may be necessary to support the project. 385.5

- Page 6-38. The SCAQMD CEQA Handbook identifies emission thresholds for determining the significant impacts of a project's primary effects (Section 6.2). The SCAQMD recommends that a primary threshold of 550 pounds per day of carbon monoxide (CO) be used to determine significance. The SCAQMD also recommends the use of modeling to determine if there are secondary effects. For example, direct CO emissions from a project may fall below the primary threshold of 550 pounds per day, but traffic impacts associated with the project could cause an exceedance of the state ambient CO standards. In such a situation, even though the emission threshold of 550 pounds per day is not expected to be exceeded directly, the project as a whole 385.6

would be considered to have a significant impact due to the potential violation of the ambient air quality standard.

The Draft EIR/EIS concludes that there is a potential for 7,017 pounds per day of CO emissions. That number far exceeds the SCAQMD's significance threshold. The modeling results show that additional CO emissions would not cause an exceedance of the CO standards. That impact is incorrectly described as "adverse, but not significant". The modeling results do not negate the fact the estimated emissions far surpass the threshold of 550 pounds per day. The SCAQMD considers the proposed project to have a significant CO impact despite the modeling results not showing an exceedance of the ambient standard. The EIR/EIS should be revised to acknowledge that potential significant impact, and all feasible mitigation to reduce the CO emissions should be included in the EIR/EIS. 385.6 (cont.)

- Page 6-42. The potential daily NO_x emissions are estimated at 2,635 pounds per day. The EIR/EIS concluded from modeling results that the NO_x emissions would not exceed either the 1-hour or the annual NO_2 standards, and therefore, would not be a significant air quality impact. The SCAQMD considers NO_x emissions over 55 pounds per day a significant impact, regardless of the results of subsequent modeling performed to determine potential violations of ambient standards. The EIR/EIS should be revised to state that the projected NO_x emissions are significant. All mitigation measures to reduce the potential NO_x increase must be included.

The U.S. Forest Service and the County of Los Angeles have primary permitting and approval authority over the proposed project as a whole. The project nevertheless will require SCAQMD permits for the gas collection and control equipment. As such, the equipment must comply with all applicable SCAQMD rules and regulations. Rule 1303 requires the SCAQMD to deny permits to construct if the modeling data indicate that the new facility will exceed allowable concentration limits specified for each nonattainment pollutant. The projected concentration change of 88 ug/m^3 NO_x for a one-hour averaging period exceeds the 20 ug/m^3 allowable concentration threshold in SCAQMD Rule 1303 (Rule 1303 Appendix A, Table A-2). The project proponent should be aware of the possibility that SCAQMD permits could, therefore, be denied even if all other state and local permits for the facility are approved. The EIR/EIS should discuss how the proponents intend to reduce the NO_x emissions such that the concentration change does not exceed the 20 ug/m^3 limit of SCAQMD Rule 1303 385.7

- Page 6-44. The potential daily SO_2 emissions are estimated at 520 pounds per day which exceeds the SCAQMD significance threshold of 150 pounds per day. The EIR concluded that the SO_x emissions would be an adverse impact, but not a significant impact. The SCAQMD considers any SO_x emissions over 150 pounds per day to be significant, regardless of the results from subsequent modeling. The EIR/EIS should be revised to acknowledge the significance of the SO_2 emissions, and feasible mitigation should be described to reduce the expected SO_x emissions. 385.8

- Page 6-46. The discussion of potential odor impacts states the project "does not have the potential to create odors over 10 dilution to a threshold that could impact sensitive receptors". There does not appear to be data supporting this conclusion. Table 21 in Appendix D provides the data 385.9

385-4

showing the ground level concentration of odorous compounds, but there is no mention of the methodology used or specific analyses in the discussion of potential odor impacts. Such a discussion should be included and the conclusion substantiated. 385.9 (cont.)

- Page 6-47. The EIR/EIS states ROC emissions from the project would be offset by other emission reductions (e.g. landfill closures) in the Basin, and significant increases in ozone would not be expected in the Class I area. This conclusion is not substantiated with supporting data. It would be helpful to include a synopsis of the methodologies used to reach this conclusion and references to the appropriate supporting data in the Appendices. 385.10

- Page 6-50. The six percent exceedance of the visibility criterion for terrain within the wilderness should be considered significant. It is inappropriate to identify a significance criterion and then claim that an exceedance of that criterion is not significant. The project impacts on visibility, therefore should be considered significant and all feasible mitigation measures presented to reduce visibility impacts. 385.11

- Page 6-51. The conclusions presented in the Effects on Forest Resources (non-Class I) do not indicate which analytical methods were used to estimate the potential impacts of nitrogen and sulfur emission deposition on the aquatic systems. Also, supporting data is not presented in the discussion or referenced in the appendices. The EIR/EIS should be revised to identify the project as significant for nitrogen deposition, and all feasible mitigation included to reduce the levels of total nitrogen to aquatic and terrestrial resources. 385.12

- Toxic Air Contaminants. There is no analysis or discussion of the potential impacts of toxic air contaminants (TAC) in the air quality section. To make the air quality section complete, the discussion of potential TAC impacts that is presented Section 7.0 - Public Health, should be at least referenced in the air quality section. 385.13

ODOR IMPACTS (Section 6.2.4)

- Page 6-52. It not clear from the discussion how a "combination of computer modeling and empirical data" were used to determine there would be no significant odor impacts. A more specific description of the analytical methods and discussion of supporting data is needed to substantiate the conclusion that odor impacts are adverse but not significant. This discussion should also be included on page 6-46 (Secondary Indicators of Significance). 385.9 (cont.)

- Page 6-53. The odor control measures do not address the necessary maintenance of the gas collection system for maximum odor control. A repair and maintenance plan should be included as a part of the monitoring program to reduce odorous emissions. 385.14

385-5

ALTERNATIVES (Section 6.3)

- Page 6-65. The discussion of the significant residual air quality impacts states PM10 ambient air quality standards will be exceeded in the immediate vicinity of the project during operation and the project will contribute to existing violations of the ozone ambient air quality standards during operations. Section 6.3 - Alternatives does not indicate that the project's criteria pollutant emissions for NO_x, ROG, PM10, SO_2, and CO are significant for both the construction phase and during the operation of the facility. 385.15

PROPOSED PROJECT IMPACTS/MITIGATION (Section 7.2)

- Page 7-15 and App. E.3. The SCAQMD does not use the LAEEM model to estimate toxic emissions from landfills and was, therefore, unable to verify the estimated emissions of toxic pollutants from the project. The SCAQMD recommends that a more detailed discussion of the methodology and assumptions be provided to allow verification of the results. The SCAQMD would be happy to assist the lead agency in preparing an analysis of the potential toxic air pollutants using the SCAQMD model. 385.16

CUMULATIVE AIR QUALITY IMPACTS (Section 19.2.3)

- Page 19-7. The cumulative air quality impacts section states "the area of concern for cumulative air quality impacts is the South Coast Air Basin." The project-specific and cumulative impacts that result from the proposed project will have an adverse air quality impact in the SEDAB as well as the Basin. The location of the project lies within an interbasin transport corridor that connects the Basin with the high desert in the SEDAB. The Soledad Canyon north of the project site connects the San Fernando and Antelope Valleys. Ozone transport into the pass was first suspected because of ozone damage to the needles of the ponderosa pine in the mountains from the northern and eastern limits of the Basin. The southern portion of the High Desert is influenced primarily by air flow moving north through Soledad Canyon from the project location and areas to the south and southwest in the Basin. Also, the EIR/EIS refers to the 1992 AQMP, the appropriate document is the 1994 AQMP. 385.17

Forest Supervisor
U.S. Department of Agriculture
Forest Service
Attention Elsmere EIS
Angeles National Forest
701 North Santa Anita Avenue
Arcadia, CA 91006

Dear Forest Supervisor:

RESPONSE TO A DRAFT ENVIRONMENTAL IMPACT REPORT/ ENVIRONMENTAL IMPACT STATEMENT (DEIR/EIS) PROPOSED ELSMERE SOLID WASTE MANAGEMENT FACILITY LOS ANGELES COUNTY PROJECT NO. 88573

Please disregard our May 4, 1995 comments on the DEIR/EIS. They were inadvertently assembled and sent without Administration review and contained Engineering Geology, Geotechnical Engineering and Transporation Planning issues raised by staff internally during review of earlier drafts of the document. These issues are either not valid, have been addressed, or have been determined to be outside our area of regulatory responsibility.

We thank you for the opportunity to provide the following comments on the DEIR/EIS for the proposed Elsmere Solid Waste Management Facility. We are continuing our review and will forward additional comments as appropriate.

Grading

Slope Stability of the proposed grading for the access road off the freeway should be addressed. 161.1

Traffic Circulation

The DEIR/EIS Transportation Element is based on 1989 traffic volumes obtained from the State of California Department of Transportation (Caltrans). Under the current County Traffic/Access Guidelines, traffic count data should not be over one and half years old. We recommend either taking new counts on all roads and intersection analyzed in the report or validate 1989 counts by conducting several new counts in the area. 161.2

161-1

In addition, we recommend the traffic report be revised to include the following items as they impact public roads in the unincorporated areas (specifically San Fernando Road at the northbound SR 14 ramps):

- The traffic study assumes all project traffic will be from the freeway, with 80 percent from the south and 20 percent from the north. We believe a portion of the northerly traffic will utilize San Fernando Road (SR 126). The trip distribution should be revised to incorporate this traffic.
- Schematic drawing showing a.m. and p.m. peak-hour turning volumes for the key intersections/interchanges addressed in the study for the existing and the future build out of the area in the Year 2010.
- An analysis of all intersections subsequent to the construction of the landfill and related facilities, including the SR 14/Los Pinetos Road interchange.
- The Critical Movement Analysis procedure used in the study to determine intersection Level of Service (LOS) should be based on the following:

  1. For dual left-turn lanes, calculations should indicate a 55 percent/45 percent split of turning volumes.
  2. Intersection Volume to Capacity (VC) should be calculated by dividing the Sum of Critical Volumes by 1,600 and adding a ten percent yellow clearance cycle. Midrange LOS D (V/C=0.85) is the point beyond which mitigation is required. If an intersection is determined to have an "existing plus ambient" VC ratio greater than 0.85 for the project completion year, then mitigation should be proposed so that the LOS is not worsened by the addition of project traffic.

- LOS analysis of key intersections/roadways should be prepared for the following scenarios:
  - Existing
  - Existing plus ambient
  - Existing plus ambient plus project
  - Existing plus ambient plus project plus related project

161.2 (cont.)

161-2

Notes for C.I.W.M.B. on ADC - 8/25/93

At the Sacramento meeting on 8/18/93, I touched briefly on many important issues related to the approval of green organic materials for ADC. Most of them have now been formally addressed by the California Organics Recycling Council and Californians Against Waste.

Today, I would like to present only two items which relate specifically to the qualification of green organics for ADC.

Number 1 - Green Organics Composting
Number 2 - Moisture Infiltration and/or Permeability Standards

In the past all organic material at the landfill was commingled with inert material. This minimized leachate production and gas generation. In the pilot study, the separation, size reduction and structuring of green organic material into a homogeneous substrate has created a very efficient aerobic composting cell. These cells will be watered weekly for fire prevention (more often in the Sierra or in the dry season). This promotes the process of "active" composting as defined in Title 14 - Chapter 3.1 - Section 17853. The temperature of these cells far exceeds 127.4 degrees F. as specified in the regulation. They are in active, controlled decomposition. Actually, the temperatures may exceed 160 degrees F. in some areas and place the material in a condition for spontaneous combustion. I wonder why no fires have been reported? This could be why a permit change was requested to reduced the overall depth of the cells from 18" to 12".

The cells by every definition in the code are composting sites. If staff is aware of these conditions, the regulations for composting pad permeability should be enforced. Staff considers the leachate on outside composting operations to be environmentally unsafe. Therefore, we must assume that the leachate from these composting cells is equally dangerous.

Are ALL regulations to be selectively and conveniently enforced as a matter of expediency ?

When this unstable, moist, actively composting mass of organic material is sealed with an overlay of additional material, an "anaerobic" condition is created which quickly forms acids and gas. Green organics hold moisture much longer than inert materials and, subsequently, this will prolong and magnify the process.

I do not believe this is competent, conservative landfill management.

This material is a volatile organic mass. Not Soil. Not earthen material. Not stabilized. Not inert. It is an active composting cell. It is not suitable for ADC !

Re: Opposition to Proposed ADC Regulations

Dear Ms. Perry:

In reply to your letter of September 17, 1993, obviously, the cities of the Greater Los Angeles area have found a loophole to evade AB939. This may be politically expedient but it is not the intent of the law. If this program for ADC is implemented it will seriously damage the economic development of the composting, mulching, soil amendment and biofuel infrastructure. All of the landfills in the state are waiting in line to bury organics as ADC.

The ratio of organics to inerts in landfills has normally been 1 to 1. The removal of inerts (metals,aluminum,plastic,etc.) due to recycling has increased the organic fraction of landfills. The replacement of inert daily cover with green organic cells will now change the ratio to the organic side at 1.5 to 1 or more making landfills more volatile. The production of landfill gas (58% methane + 42% CO_2) will increase substantially. The addition of water (for fire prevention) also accelerates this "anaerobic" process. The result is a more efficient methane generator and added profit for the landfill operations. (It has been reported that 17 landfills in the state have methane collector systems.)

The higher permeability of the landfill will allow increased migration of landfill gas. The slope faces covered with porous green materials are actually chimneys to the surface.

The collection systems now in place can capture 50% of the gas production. The balance escapes to the atmosphere. These are poisonous, greenhouse and ozone depleting gasses. Many landfills cannot grow vegetation in post closure due the seeping methane gas. Flash explosions are not unusual.

Studies show that a 12,000 ton a day landfill, with the most modern equipment, collects approximately 12 million cubic feet of gas per day. The balance (50%) escapes into the atmosphere. This is equal to 40 acres 6.9 feet deep. The school gym next to the Sheldon-Arleta was closed until the methane intrusion could be controlled. The use of green organics for ADC will increase the volume of methane and other volatile gasses dramatically.

BIO-THERMIC
RESOURCE
RECOVERY
Organics Processing Systems
P.O.Box 2448 - Salinas, CA - 93902 - (408)759-7441 - (FAX)759-7442

The increased porosity of the landfill will allow oxygen to be drawn inward from the surface during gas recovery operations. This promotes internal landfill fires. Operating Industries Landfill #19AA-0836 in Monterey Park burned for 12 years.

The California laws are quite clear on this point and the board is directed by code as follows:

PRC code #40051 - Calls for implementation to be "environmentally safe".
PRC code #40052 - States the boards purpose is "to protect air and water quality, to improve the regulation of existing solid waste landfills".
PRC code #43030 - Calls for "control of the subsurface migration of landfill gas" and "make recommendations, as needed, to improve the program".
PRC code #45300 - States "due to the migration of methane gas" "take corrective action as necessary to" "protect human health and the environment".

The approval of green organics for ADC violates the PRC codes as cited above. The use of green organics for ADC is also in direct conflict with the intent of AB939.

If you are going to violate the PRC codes, at least don't do it so flagrantly. An interim policy (which we believe is, nevertheless, a violation of the PRC codes) should provide an incentive for the development of permanent recycling operations. To this end, we would suggest that no more than 50% of the green waste as shown in the SRRE be permitted as diversion allowance and tipping fees should be no less than 80% of the "full burden" cost per ton. It could say that no more than 25% of the normal ADC may be replaced by green waste (this will help to maintain the integrity of the landfill). In addition, such an interim policy could say that the depth of daily cover should not exceed that amount required for suitable performance. Finally, the policy could say that the balance of the green material should be banned from landfill as is done in more than ten other states.

We would urge the board to continue the development of a suitable permeability and flammability standard for ADC. Many organic materials (MSW) will make an excellent ADC after a composting operation stabilizes and reduces them to a "soil like" product. They will be inert and in most cases superior to the native soils now being used. (Note: Most of the so called "native soil" now being used has little or no value in agriculture. The green material being buried will rebuild depleted soils.)

RESOURCE
RECOVERY
Organics Processing Systems
P.O.Box 2448 - Salinas, CA - 93902 - (408)759-7441 - (FAX)759-7442

As noted above there is a correct method for the use of organic material (MSW) as daily cover. The use of unstabilized green materials is not the correct procedure nor in the best interest of public safety. The proposed policy creates a permanent public liability in post closure management for many decades.

In sum, the use the use of green organics for ADC will:
- *increase the organic fraction of landfills
- *increase the production of landfill gas
- *increase the migration of landfill gas
- *accelerate the anaerobic process
- *promote landfill fires
- *harm markets for organics recycling
- *diminish the incentive for cities to reduce the amount of materials that end up in landfill

Thank you for the opportunity to comment on this issue.

Sincerely,

Bill Newland

SUBJECT: *WHY 23 STATES HAVE BANNED GREEN WASTE FROM LANDFILL!*

Global warming studies by NASA have identified the composition of greenhouse gas. It is 55% CO_2 and 15% CH_4 (methane). Landfill gas (LFG) is 43% CO_2 and 55% CH_4 (MSW Management - December 1994). Landfills rank 6th in the creation of these greenhouse gases. The removal of unstable, compostable organics from landfills and the control of ozone depleting and greenhouse gases is a major environmental priority.

A landfill with currently available equipment can recover 50% of the CH_4 production. Given a 12,000 ton a day facility, the average recovery is 12 million cubic feet. The use of volatile organic material as alternate daily cover (ADC), collected into working cells with water added, can increase this volume 2 to 6 times. One landfill of this class using green waste as daily cover collects 32 million cubic feet per day (Waste Age - Sept. 1993). This system then allows 32 million cubic feet of CH_4 and 59 million cubic feet of CO_2 to be released into the atmosphere daily. Enough to cover 2000 acres 1 foot deep every day. 760,000 acres every year. From one landfill.

Operations of this type are in violation of the Federal Clean Air Act (sections 111(b) and 111(d)), the New Source Performance Standards, Global Climate Protection Act of 1987, Framework Convention on Climate Change (Earth Summit 1992), Presidential Climate Change Action Plan (October 1993) and a federal directive to the EPA "...to formulate a tough *rule to reduce methane emission from landfills* under section 111 of the Clean Air Act. This rule, which will be completed this year, will increase the amount of organic compounds that must be recovered by landfills..." (Climate Change Action Plan - October 1993).

As we have previously sited in our correspondence (on record) with the CIWMB, specific PRC codes and Subtitle D, 40 CFR Part 258 are being totally ignored regarding permeability, LFG migration, fire control and other requirements for ADC which affect the qualification of organic materials. The use of green waste and other compostable organic material for daily cover is in violation of these codes and caters to those who are evading the mandates of AB939.

Professional landfill operators can document fires, explosions and surface collapses at every landfill site in California (over 100 in the L.A. basin). We suggest that an unbiased survey be taken of these hazards before any organic material is authorized for daily cover.

The general public has accepted the importance of recycling. They are participating with collection programs and by paying increased collection/landfill fees to support it. The cost of qualified ADC and composting was calculated by the franchised operators when the fees were increased (a continuing scenario). Now they want to eliminate that plan and keep the increased fees. This appears to be nothing more than political double dipping.

The garbage companies and haulers must keep up gross incomes in the face of reduced volume. Their answer has been to lobby, stall and obstruct the composting regulations for almost four years. They believe that the communities and CIWMB will allow them to keep the increased fees and continue to landfill organic materials.

The municipal solid waste stream is 50% to 60% organic materials (clean green, biosolids, food processing residue, paper, biogenics, race track bedding, etc.). If they are to be used as ADC or final cover, the proper method is to compost them into a stabile product (as well run landfills are doing) before application. We can not change their name to ADC and continue to bury them in the landfill.

This is not recycling to the highest and best use.

The improper use of unstable organic material for ADC has been well documented by our papers over the last 18 months. The board allowed one sanitation district to claim 7% of their total stream as ADC and diversion allowance on a temporary basis while the composting infrastructure was developed and while the CIWMB staff established a standard on permeability for ADC. After 12 months, this has not happened and all landfills now want organics for daily cover.

The greater Los Angeles area composting infrastructure has stagnated and it may never be developed as long as the L.A. Sanitation District takes in green material for $9.00 a ton and buries it as daily cover.

The CIWMB, with all of the PRC Code directives and more than sufficient data from the pilot projects, has not given us a composting regulation or a permeability specification for ADC as promised. How can the composting industry develop with out guidelines?

The unsuitability of volatile, virgin organic cells for daily cover is easily understood by everyone.

Green material is particularly unsuitable:

1. It requires additional water to combat fire hazard. This helps increase methane production 2 to 6 times. In the greater Los Angeles area, the landfills with collection systems (which are only 50% efficient) recover 102 million cubic feet a day of CH_4 (Waste Age - September 1993). This means that over 100 million cubic feet per day are released into the atmosphere.
2. Landfill gas is 43% CO_2. Leading climatologists and NASA have identified CO_2 as the major contributor (55%) to greenhouse gas. The CO_2 release from only the landfills with collectors in the greater Los Angeles area can be estimated at 200 million cubic feet daily under landfill practices of 1993. This equals 725,000 automobiles operating for 1 hour at 40 mph. Green waste used as ADC "increases" CO_2 production 2 to 6 times.
3. With the increased anaerobic production of CH_4 (methane) and CO_2, organic acid production is increased equally. These acid leachates penetrate current clay liners in about 30 minutes. When not trapped by the collection system, they continue on to pollute the ground water or they remain to increase LFG production.

All of these problems will continue at public expense for decades after landfill closures.

Every composting facility requires some form of bulking agent. This could be sawdust, rice hulls, straw, cotton gin waste, etc.. However, the only material with statewide distribution is clean green fines. They should not be landfilled.

The footer on the November 1994 newsletter from the CIWMB states, "The six member Integrated Waste Management Board is responsible for protecting the public's health and safety and the environment" and "while ensuring environmentally safe land disposal capacity."

The Composting Council "supports the removal from landfill and composting of all organics, which cannot be put to a higher and better use, to replenish the depleted and eroded agricultural soils of America."

We agree. Thank you for your time.

Bill

CAMPO SOLID WASTE MANAGEMENT PROJECT

DRAFT ENVIRONMENTAL IMPACT STATEMENT

DES 92-6

February 1992

Lead Agency: U.S. Department of the Interior
Bureau of Indian Affairs
Sacramento Area Office

Cooperating Agencies: Campo Band of Mission Indians
Campo Environmental Protection Agency

Prepared by: Science Applications International Corporation
Environmental Programs Division
121 Gray Avenue, Suite 101
Santa Barbara, CA 93101

For Information Contact: Donald Knapp
Bureau of Indian Affairs
Sacramento Area Office
2800 Cottage Way
Sacramento, CA 95825
(916) 978-4703

Abstract:

The proposed action consists of BIA approval of a lease between the Campo Band of Mission Indians and Muht-Hei, Inc., a tribally chartered, wholly owned corporation of the Campo Band. The lease would permit the use of reservation land for the construction and operation of an integrated solid waste management project. The technical services of Mid-American Waste Systems, Inc., and Campo Projects Corporation would be used pursuant to subleases and other agreements. The project would involve the shipment of wastes from off the reservation for disposal or recycling at the Campo solid waste management facilities. Several alternatives, including the no-action alternative, were analyzed in the Draft EIS.

Last Date for Receipt of Public and Agency Comments: May 8, 1992

For landfill gas collection systems (i.e., systems of collection wells and pipes), the SCAQMD found that the overall effectiveness in reducing emissions varied between 72 and 100 percent, with most data points falling in the 81 to 88 percent effectiveness range. According to EMCON Associates, "The gas generated in a landfill escapes by migration through the base, sides and top. A landfill design that restricts, or precludes, migration from these perimeter areas enhances gas management and recovery efficiency" (EMCON 1990). The proposed landfill cap system includes a 40 mil very low density polyethylene (VLDPE) liner. The bottom and sides of the landfill would be lined with two high density polyethylene (HDPE) liners. This system would serve to prevent or strongly inhibit off-site landfill gas escape, due to lateral landfill gas migration or migration through the landfill face or cover.

The project must comply with CEPA air quality management regulations. CEPA has adopted regulations that are based on and are consistent with San Diego County Air Pollution Control District (APCD) regulations, including APCD Rule 59 - Control of Waste Disposal Site Emissions. Rule 59, Paragraph (d)(1)(ii)(A), specifies that the concentration of organic compounds cannot exceed 500 ppm (as methane) at any point measured immediately above the landfill. This requirement applies to closed and covered cells as well as to open cells. The liner system should easily allow compliance with this standard for closed cells. Installation of a gas collection system during the working life of the open cell should also allow compliance for the open cell. Existing landfills in San Diego County meet Rule 59 by installing collection systems while the cell is being filled rather than afterward.

When combined with proper contouring and installation of the gas collection system piping, the liner is expected to result in a gas collection effectiveness of 95 to 99+ percent. A collection effectiveness of 95 percent has been assumed for this analysis. The presence of micro-biologic organisms in the cover soil could cause emissions of fugitive ROG to be further reduced.

The 95 percent of landfill gas that is captured would be flared with most of the organics destroyed in the process. The U.S. EPA has proposed New Source Performance Standards (NSPS) for municipal solid waste landfills (EPA 1991). These standards would require at least 98 percent destruction efficiency for organic compounds. The document states that "The EPA concluded that properly designed and operated flares, both open and enclosed, can achieve this efficiency (i.e., 98 percent) with landfill gas." Flares were also determined to be the most cost effective method of destroying organics. For this analysis, a 98 percent destruction efficiency is assumed for organics, including carcinogens.

4.3.2 Landfill Gas Emissions Impact Analysis

4.3.2.1 Proposed Project

Landfill gas emissions from the proposed project would result from flaring of captured gases and escaping fugitive gases. These emissions would include both criteria pollutants and toxic air contaminants. Impacts of criteria and toxic pollutants are discussed individually below. The impact analysis is based on project buildout, with the landfill filled to capacity. Emissions to the air would be generated by each landfill cell, with the same emission profile repeating over time as each cell is filled and closed in sequence, as described in subsection 4.3.1.3.

Criteria Pollutants

Criteria pollutants include nitrogen oxides (NO_x) in the form of nitrogen dioxide (NO_2), carbon monoxide (CO), particulate matter (PM_{10}), and ROG. Small amounts of sulfur dioxide (SO_2) may also be generated but these amounts would be negligible and are not discussed further. All of these pollutants occur during flaring. In addition, ROG emissions are contained in the uncaptured fugitive emissions.

VILLA PARK; Old Waste to End Up in Yards

BILL BILLITER

In an unusual turn of events, city residents last week welcomed the return of some of their garbage.

The waste once was tons of lawn clippings, leaves and garden trimmings from Villa Park. It was recycled into commercial compost, and processor Scotts Co. has given away 25 tons of it for local gardeners--as much as 60 gallons a household.

The city's commercial trash collector, Villa Park Disposal, coordinated the compost giveaway. The company is a division of the Anaheim-based Taormina Industries.

"We did this as a way of saying 'thank you' to residents for their strong support of recycling and also as a way of closing the loop--bringing it back . . . so it could be used again," said Lori Rolleri, director of corporate communications for Taormina Industries.

Rolleri said Villa Park residents divide their trash among three containers: one for general garbage, one for material recyclables such as aluminum cans and glass, and one solely for green waste. The green waste is converted by Scotts into commercial compost.

If the city did not have the recycling program, tons of green waste would be dumped into county landfills, Rolleri said. "It would not only reduce the size of landfills quicker, but it also would be producing methane gas, which adds to the global warming."

Villa Park is now among the top cities in the United States in trash recycling, Rolleri said. "Sixty percent of the city's residential waste is now recycled," she said. "Villa Park has done exceptionally well."

Recycling Christmas trees urged by city and county

Monica Mendoza

After the holidays end and the presents have been unwrapped, that gorgeous Christmas tree is nothing more than dead wood.

So why not make it mulch?

A Christmas tree recycling program, "Treecycling '97," encourages residents to make mulch of cut Christmas trees and replant live Christmas trees.

The program sets up drop-off sites at all three local Home Depot stores and provides curbside pick-up for cut trees.

Officials estimate that 17 percent of the waste in the landfill is "green waste" - trees and plants - and could be recycled, said Erin Kimrey, Tucson waste reduction planner.

The Christmas tree recycling program is the first step in a full green waste recycling program, she said. Green waste in the landfill, when decomposed, can produce the dangerous methane gas. The city eventually wants to keep all green waste out of landfills.

"We are very anxious to find out how many Christmas trees we can divert from the landfill," Kimrey said.

Residents can take their cut trees to the Home Depot stores - 1155 W. Irvington Road, 7102 E. Broadway and 4755 N. Oracle Road - from 8 a.m. to noon Jan. 4 and Jan. 11. In exchange, residents will given a goody bag with information about composting, recycling, and other local environmental programs. All the collected trees will be chipped and made into mulch by Desert Organic Products, a division of Arizona Tree and Landscape Service; Desert Compost, a division of Groundskeeper; and Pima County Solid Waste Department.

Tucson Parks and Recreation Department will accept live Christmas tree donations and plant them in various city parks.

Residents may take live trees to the city's Parks and Recreation Department's administration building, 900 S. Randolph Way, between 8 a.m. and 3 p.m. Monday through Friday.

Last year, the city took in about 20 trees and replanted them, said Glenn Hicks, who runs the city nursery.

Trees that are too small to be immediately planted outside will be kept in the nursery.

"Eventually most of them get planted," Hicks said.

The city's Solid Waste Management Department will collect cut trees left on curbs during January and early February. Those trees also will be chipped into small pieces for use as mulch to re-vegetate city landfills.

Pima County also is accepting cut trees during their regular operating hours at the Ina Road Landfill, 530 W. Ina Road, and Catalina Transfer Station, 14425 N. Oracle Road.

For information about how to assist with the Christmas tree recycling effort as a volunteer, call 791-3171.

Surveying household hazardous waste generation and collection: trends in Arizona.

Ann Marie A. Wolf Lori E. Kettler J. Fred Leahy Anna H. Spitz

Introduction

Many common household products used in the kitchen, bathroom, garage and basement have the potential to cause serious health and environmental problems during their use or after their disposal. Consumers use a host of specialized, powerful cleaners, paint and paint-related material, pesticides and a wide variety of automotive products. When the consumer disposes of these materials, they become wastes. These potentially hazardous chemicals are readily available in most retail and wholesale establishments. Most are purchased over the counter by any person, in any age group, at a variety of locations such as grocery stores, hardware stores and automotive centers. HHW are exempt by definition from federal and most state hazardous waste regulations; accordingly, they are not subject to the stringent regulations that industry must follow, even though many of the products have similar chemical ingredients. Little information is available on the direct effect of these materials on the environment. Until recently, studies have focused on regulated waste and not the effect of HHW in municipal solid waste (MSW).

The Garbage Project at the University of Arizona in Tucson, Department of Anthropology, has collected the most comprehensive consumer usage data by conducting detailed residential-refuse characteristic studies in the Tucson community. The primary thrust of the HHW characterization studies has been to count the number of hazardous items (containers). They concluded that the approximately 120,000 households in Tucson generate approximately 11 million hazardous items annually (1). In 1989 the Garbage Project collected curbside waste in four urban communities (Tucson, Phoenix, New Orleans and Marin County, CA). The HHW weight fraction was between 0.42 and 0.61 percent of the refuse weight. The study's final conclusions were: 1) although HHW is relatively small in proportion to the total MSW analyzed, significant quantities are discarded each year; 2) great diversity in HHW types exists; however, certain wastes represent a major proportion of the total by weight; 3) differences among communities in types and quantities of HHW are quite distinctive; and 4) landfilled residential waste may contain higher concentrations of hazardous materials than commercial wastes (1).

In response to growing concerns about HHW, collection programs were implemented in the early 1980s. From 1980 to 1994, the number of HHW collection events per year in the United States grew from two to almost 1,700. Thirty states have established permanent HHW programs. Unfortunately, most of these programs collect from only two to six percent of the general population and have an extremely high per-participant cost (2,3,4,5). Use of HHM has not significantly declined even though products such as SAFETY Stripper[TM] and batteries without heavy metals have entered the market. Homes storing HHM and unsafe disposal of HHW are problems still facing communities.

Health and Environmental Problems

When household products are used, misused or improperly stored or disposed of, residents are most likely to be exposed to dangers and long-term exposure. Materials that are used infrequently are often stored in closets, basements or garages for long periods of time. Materials such as paint thinner solvents and fertilizers may react with their containers over years causing the containers to deteriorate, thus increasing potential danger to homeowners. Over 90 percent of poisonings in the United States occur in the home. In 1994, 45,311 exposures to bleaches containing hypochlorite were reported to poison control centers in the United States (with 8,657 of those treated in a health care facility) and 3,850 exposures to ammonia cleaners were reported (with 642 treated in a health care facility) (6). Nationwide in 1993, 140,000 exposures to pesticides were reported, 93 percent of which involved home use. About 25 percent of these reported pesticide exposures involved poisoning symptoms, and over half the exposures involved children under age six (7). Household products continue to be the major source of poisoning among children (6).

HHW alone or in combination with other substances can pose hazards to refuse collectors and workers at landfills and incinerators. HHW causes injuries to approximately three percent of waste collectors through explosions, acid or caustic splashes and burns from flammable substances (8). For example, a refuse worker in California lost his sight when HHW spilled on his face. A firm in Lemon Grove, California reported incidents in which swimming pool chemicals splashed on personnel during the compaction of residential refuse. Personnel from Tempe, Arizona reported an average of five fires in the city's residential packers each year, primarily from chemicals.

Leachate is produced as water percolates through solid waste, leaching soluble components and degradation products from refuse. Researchers from Texas A&M University found that leachates from MSW landfills that do not accept industrial waste contain many of the same compounds found in industrial waste. The presence of these compounds was attributed to the presence of HHW or illegally dumped regulated waste (9). Studies show that even rural landfills that

have had no type of industrial source, have organic chemicals in the leachate (2). A U.S. Environmental Protection Agency study found hazardous organic constituents in the leachate of all 53 landfills analyzed (10). An estimated cancer risk calculation resulted in evidence that MSW landfill leachates are as acutely and chronically toxic as co-disposal and hazardous waste landfill leachates (11). In fact, the leachates from two of the MSW landfills that opened since the regulations prohibiting codisposal of hazardous waste went into effect have cancer risks greater than the Love Canal landfill leachate.

The use of landfill liners, both synthetic and compacted clay, and leachate collection systems decreases the risk of groundwater contamination by landfill leachate. However, leachate collection systems may not be pumped out frequently enough, and even plastic liners leak (an average of 13 holes per acre). These limitations cause groundwater to be contaminated with landfill leachate. Recent data indicate that volatile organic compounds commonly found in landfill leachate can rapidly migrate through synthetic liners, even at dilute concentrations. Organics also can diffuse through compacted clay liners (11). Landfilling HHW may not be the best long-term solution.

Many of these wastes are disposed of in an indiscriminate manner that may ultimately degrade surface water, groundwater and air quality (12). A Seattle study on the sources of hazardous chemicals to the municipal sewage treatment plant showed that for a number of contaminants, the non-industrial sources were much higher percentage contributors than any of the industries (2). Residential sources contributed seven to 11 percent of the heavy metals, and 55 to 64 percent of the extractable organics ending up at publicly owned treatment works. Another study found no difference in metal or organic concentration in wastewater for cities with low and high industrial use (8). One third of all U.S. housing uses septic tanks. Organic cleaners, solvents and paint thinners do not bind to soil particles. Instead they go right through these systems and into the groundwater (2). A California Air Resources Board study determined that the overall composition of landfill gases from hazardous and non-hazardous sites appear to be similar. The study stated that non-hazardous landfills may contain concentrations of toxic gases equal to or exceeding those of hazardous landfills (10).

Lack of Knowledge

Large United States businesses have made great strides in instituting pollution prevention and waste minimization programs to employ chemicals in safer and more cost effective ways. On the other hand, general consumers often do not know they are using, storing and discarding hazardous products. Many individuals do not think that the use or disposal of household products poses a threat to their health and environmental quality. A Colorado survey

reported that 20 percent of the respondents were unable to identify a single toxic product in their home (13). While the majority correctly assessed the damage potential for pesticides, dishwasher soap and paints, most failed to accurately assess the potential for environmental damage if drain cleaner, motor oil or antifreeze are improperly disposed. A New Mexico survey had similar results: only 28 percent surveyed could name one hazardous product, and 12 percent could not name any (14). Homeowners remain unaware of the dangers of the products in their homes, and the notion that "one can of oil on the ground can't hurt" is pervasive.

Methods

Maricopa County, Arizona

The study was conducted among households in Maricopa County, population of 2,209,567 and area of 9,204 square miles. The county includes the cities of Phoenix (pop. 1,012,230), Mesa (pop. 296,645), Glendale (pop. 156,165), Scottsdale (pop. 137,022) Tempe (pop. 150,615), Peoria (pop. 65,500) and Chandler (pop. 100,173) (15). A random digit dialing system was used to obtain a sample of Maricopa County residents aged 18 years or older. Specifically, a review of current telephone directories revealed that 237 telephone prefixes served the geographical boundaries of Maricopa County. A random four-digit number was joined to each prefix. A percentage of surveys were completed based upon the population in each telephone prefix area. The sample size (244 completed interviews) was determined by demographic consideration, the amount of data needed to test the computerized survey instrument and the results from previous awareness surveys conducted by Pima County for a representative sample of the population. A larger sample size would be required in order to complete thorough statistical inference calculations for all the disposal data.

Residents of Maricopa County were surveyed by telephone using a computerized or hard-copy survey instrument. The survey questions asked about the following: products purchased, disposal practices, knowledge of HHW and HHW programs, awareness of health and environmental problems and preferences for disposal and funding options. The survey results were entered into a computer database and modeling program, which calculated the statistics. The program also estimated the amount and types of hazardous waste being improperly disposed of and the potential exposure from the improperly disposed material. Calculations included the following:

* all demographic statistics

* percentage of participants purchasing specific hazardous materials

* amounts of hazardous materials stored and/or disposed of and disposal methods

* percentage of participants aware of HHW and related health and environmental effects

* percentage of participants who use and/or are aware of collection programs

* potential participation in collection programs

* opinions about collection and funding options

* significant differences between responses

Pima County, Arizona

The City of Tucson/Pima County Household Hazardous Waste Program is the only permanent collection facility in Arizona. Along with the permanent facility, satellite collection events are held at least once a month throughout the county; the municipal landfills have battery, oil and paint collection sites. The program has become the model for other programs in Arizona. The program has a participation rate of five percent and a cost per participant of $43 for fiscal year 19951996. The study was conducted among users of the program at the permanent facility and/or a satellite event. Approximately 12,000 face-to-face interviews were completed when the participants brought their waste to the program. The questions asked the length of time the material had been stored, how often they used the program and how they had heard about the program. Selected demographic data were collected. Eight hundred participants also were asked what they would do with the waste if no program were available.

TABLE 2

Results-Maricopa County

Demographics

Selected demographic data reported by the study participants and the corresponding 1990 U.S. Census Bureau figures for Maricopa County are given in Table 1. The demographic data for study participants were similar to the data for all residents of Maricopa County except males, who were underrepresented. In many two-person households surveyed, the female answered the telephone and subsequently was surveyed.

Material Usage and Disposal Options

Ninety-six percent of the residents surveyed had purchased hazardous materials in the last year (95-96). The percentage of residents that purchased specific categories of hazardous materials is listed in Table 2. "Batteries" was a subgroup of miscellaneous items. Most residents used up significant portions of their paint products (62%), pesticides and fertilizers (89%) and cleaners (90%), but used up only 46 percent of their automotive products and only eight percent of their miscellaneous items (batteries, hobby chemicals, and pool chemicals for example). Residents were asked what they did with the waste or products that they no longer used. As shown in Table 3, all categories of waste were put in the garbage, including 86 percent of the miscellaneous items and 57 percent of the cleaners. An additional 26 percent of the cleaners were taken to the landfill. Over 66 percent of the waste automotive products were recycled or taken to a collection program; however, five percent (all antifreeze) were disposed of on the ground. Significant quantities of automotive products (18%), paint and paint products (55%), and pesticides and fertilizers (39%) were stored.

Residents were asked to estimate the amount and frequency of material disposed of, as shown in Table 4. Over 20 gallons of paint were improperly disposed of with half of the material poured onto the ground. Over five gallons of antifreeze were poured onto the ground; over four gallons of cleaners poured down the sink. Over seven gallons of paint and 1,989 household batteries were put in the garbage.

Health and Enviromental Perception

To determine awareness of HHW and the potential health and environmental problems, residents were asked if they had heard the term "household hazardous waste" prior to the survey and if they thought HHW caused health and environmental problems. Over 68 percent of the participants had heard the term HHW and believed that the products caused health and environmental problems. However, 31 and 24 percent of those surveyed did not believe or did not know that HHW could cause health or environmental problems respectively. A statistically significant lower percentage of males than females thought the products caused health problems. The

results by male and female are shown in Table 5. No significant difference in response was found between income and education levels as has been reported by Schultz et.al. (16).

Preferences for Disposal and Funding Options

Maricopa County has no unified approach to HHW collection, however, several communities do provide annual events. In 1995, Phoenix had approximately 2,000 participants, while Tempe had approximately 600 for one-day events. Twenty percent of the survey participants knew of the collection events in Maricopa County, and 53 percent of those used the events. When surveyed on their preference for HHW collection, 54 percent of the residents preferred a permanent collection facility, while 25 and 6 percent preferred a collection day or curbside pickup respectively. The preference for a permanent collection facility is in agreement with other surveys (17,18).

Of those that chose a permanent facility, 57 percent were willing to drive up to five miles to use the facility, 22 percent up to 10 miles and 12 percent up to fifteen. When asked how a safe disposal option should be funded, 23 percent of the residents chose a tax on products when sold; however, over 30 percent of the participants didn't know or gave no response to this question as shown in Table 6. Only 26 percent stated they would use the facility over three times a year and 32 percent stated twice per year. Of those that chose a collection day, 20 percent stated they would use a collection day over three times a year and 29 percent stated only once per year.

Results-Pima County

Sixty-seven percent of the participants were repeat users of the collection program with over 50 percent using the facility more than three times per year. When asked what they would do with the waste if no program were available, 36 percent of the participants responded that they would throw it in the garbage. The majority of new participants had stored their waste for over a year, while the majority of repeat participants had stored their waste for less than three months. Over 75 percent of the participants had heard about the program through word-of-mouth rather than advertisements or announcements.

The percent by weight of waste categories collected by the facility for fiscal year 19951996 are shown in Figure 2. It collected 422,953 pounds of HHW, of which over 50 percent consisted of automotive products (41 percent was used motor oil) and 26 percent of paint and paint-related material.

Discussion

Even with the majority of the residents in Maricopa County properly disposing of their HHW, significant quantities are being

disposed of improperly. Both surveys, Figure 1 and Table 3, show similar trends with storing and throwing in the garbage being the most common responses. With a collection program participation rate of only five percent, Pima County landfills are also receiving significant quantities of HHW. Even small quantities of improperly disposed material per person result in significant loading of HHW to the municipal facilities and the environment. As demonstrated by both surveys, many of the methods chosen for "disposal" when a program is not available are potentially dangerous to human health and the environment.

Program Design and Operation

The preference of Maricopa County residents for a permanent facility and a drive of less than five miles requires several permanent facilities for a county the size of Maricopa. Permanent facilities have advantages over satellite collection events but may not be feasible initially. Pima County has conducted satellite collection events for ten years, but has the long-term goal of establishing permanent facilities throughout the county. These permanent collection sites would be supplemented by roving neighborhood cleanups and collection programs at the landfills. In addition, sites would be open every weekend, providing residents with more flexibility, and collection activities would be spread throughout the month. Currently, high output of staff and volunteer labor is required the first weekend of every month.

TABLE 5

Perceptions and use of program by participants

Question	Female %	Male %
Aware of pollution problems	77	74
Aware of health problems	74	62
Aware of HHW	82	62
Aware of collection programs	24	15
Use of collection programs	13	8

TABLE 6

Funding options chosen by participants

Funding Option	Percent (%)
Small charge on each item when disposed	16
Small increase in garbage collection or landfill fees	12

Tax on products when sold	26
Would not be willing to pay	12
Other	7
Don't know	16
No response	12

Actual usage rates for Pima County are significantly different from those predicted by the Maricopa County survey. With 67 percent repeat users, residents are developing the habit of taking their HHW to the collection center as it is produced. Once established, participants may use a facility more frequently than projected.

Waste streams from Pima County can be compared to the projected waste streams from the Maricopa County survey. Automotive products and paint and paint-related material were the waste streams (besides batteries) that were least frequently used up by the participants. Maricopa County can expect to receive automotive products and paint and paint-related material as the two main waste streams. If Maricopa County collects only automotive products and paint and paint-related material, it can collect over 80 percent by weight of the waste. Focusing on limited waste streams may be an efficient way to begin the program. These waste streams are easy to collect and handle and can be recycled, reused or sent for fuels blending. The Maricopa survey predicted that large numbers of household batteries would be collected. Pima County collected 4,292 pounds of batteries last fiscal year, which represents approximately 214,600 AA batteries, only approximately 1% of the total waste collected by weight. Inferring from the Maricopa survey, these collected batteries are less than what 24,000 to 30,000 people throw out per year, about three percent of the population of Pima County.

Educational Program Implications-Pima County

Traditional public education programs, which focus solely on collection of waste, have the potential to greatly increase the amount of HHW collected at the facility and also the money spent on disposal. The goal of the current educational program is to decrease usage of HHM and production of HHW in the community. Based on the survey demographic data (zip codes), two satellite collection sites were closed and one new site opened. Public awareness programs were increased in areas with low participation rates. However, reliance solely on traditional advertising is being replaced by school curricula and outreach programs, bilingual materials and cooperative neighborhood and retail take-back programs. Even though the facility has the capacity to handle large quantities of material, the program is shifting from a collection to prevention emphasis. The shift in emphasis addresses public

health concerns during the use of HHM as well as HHW collection.

Conclusions

The survey represents the first step in long-term HHW planning for Maricopa County. The results indicate that the majority of residents in Maricopa County use up or properly dispose of the hazardous materials that they purchase. However, even with the majority properly disposing of their waste, significant quantities of HHW are being improperly disposed of. Of concern is the fact that 29 percent of those surveyed did not believe or did not know that HHW can cause health problems, and 23 percent did not believe that HHW can cause environmental problems. Of further concern is that the Pima County program, a ten-year old program with a public awareness campaign, has a participation rate of only five percent. Many residents remain unaware of the potential problems associated with using HHM and disposing of HHW. Motivation for using the existing programs remains low.

Even though the surveyed participants preferred a permanent collection facility, this may not be feasible initially for Maricopa County. The county may need to follow the Pima County model with satellite collection events and battery, oil and paint collection sites at municipal facilities in addition to a permanent site that could be later expanded as needed. Results indicated that the participants were open to an additional tax or fee to fund the program. The Pima County program is funded by existing revenues and sale of recyclables. All suggestions of additional fees or taxes have been opposed by its users.

Collection programs must be supplemented by strong educational programs. These educational programs must demonstrate how HHW can affect both human health and the environment, and must emphasize decreased usage of HHM and production of HHW. Educational programs that only emphasize collection have the potential to physically and financially overwhelm programs with collected waste and focus on only one part of the problem, the end product. Removing HHW from the municipal waste stream was the initial motivation for most programs; however, programs must now expand to address usage, safety and prevention as well.

Grizzly bear proposal will go public today Federal plan to restore Ursus horribilis in Idaho

Ken Miller
Staff

calls for bringing them to Selway-Bitterroot area

The U.S. Fish and Wildlife Service will release its plan today to restore grizzly bears to rugged central Idaho, backing a compromise to put the bears' future in the hands of a citizen management team for what could be a century-long recovery effort.

The proposed grizzly recovery plan calls for the shipment of three to five bears a year into the Selway-Bitterroot for five years, building an "experimental, non-essential" population that could take 100 years to reach a recovery level of 200 to 300 animals.

Alternatives not recommended for approval but still on the table include returning bears with full endangered-species protections, not allowing grizzlies in the area, and letting grizzlies try to colonize on their own.

The bears are to be delivered into the Selway-Bitterroot, but the core recovery area is expected to include the adjacent Frank Church-River of No Return Wilderness. A larger "experimental population area" - 15 million acres bordered by U.S. 93 on the east and U.S. 95 on the west, Interstate 90 on the north and Banks and Salmon on the south - would allow for more management than normally accorded endangered species.

The bears would be managed by a 15-member Citizen Management Committee. The panel, serving six-year terms, would be appointed by the Interior secretary. The Idaho governor would recommend seven members for the panel, Montana's governor would name five, and the Interior secretary, Nez Perce Tribe and the Agriculture secretary each would submit one name.

Hearings on the plan will be conducted Aug. 27 in Salmon and in Hamilton, Mont.; Aug. 28 in Lewiston and Missoula; and Aug. 29 in Boise and Helena.

Getting involved

For the first time, the U.S. Fish and Wildlife Service will make the massive grizzly bear draft environmental impact statement available to the public on a special Internet World Wide Web site: http://www. r6.fws. gov/end spp/grizzly

Re: Sunshine Canyon Landfill Expansion
Request for Extension of Comment Period

Dear Mr. Howe:

I have been provided with a copy of your letter to Council Member Hal Bernson on October 8, 1997. Your letter acknowledges that the Sunshine Canyon Landfill DEIR is "difficult to review," and that the City is entitled to designate a comment period of greater than 90 days in "unusual situations," yet you agreed to extend the comment period for only 30 days instead of the 90 days requested by Council Member Bernson.

The only justification offered in your letter for refusing this requested accommodation is that many of the issues requested in the City DEIR "were also addressed in a previously released EIR for the County Los Angeles which has been reviewed by the public." Unfortunately, your letter fails to recognize that public's primary opportunity to review the County EIR occurred almost ten years ago. Since that time, many members of the public who submitted comments on the County DEIR have died or moved away, and during the same period of time new residents have moved into the area to be affected by the landfill expansion; these new residents have not had a reasonable opportunity to become familiar with the issues presented in the County EIR, which is in itself a complex document consisting of several thick volumes which are if anything even more difficult to understand that the City DEIR. You should also be aware of the fact that BFI has refused to provide copies of the City DEIR to community organizations and interested individuals who have requested it, and has instead cynically sent the EIR to community organizations in areas far away from the landfill, thus making it even more difficult for members of the public to respond effectively. Finally, BFI's prolonged delay in releasing the City EIR means that it is in no position to object to the relatively brief extension sought by Council Member Bernson.

Planning experts recognize that the siting of a municipal landfill raises "extraordinarily difficult" public policy issues

12841 JIMENO STREET GRANADA HILLS CA 91344 (818) 360-7635

(see, for example, page 788-89 of the Spring 1994 edition of the Fordham Urban Law Journal. This is particularly true in view of the fact that, as noted in the Azusa Land Reclamation case, the California legislature has declared that landfills constitute a "threat to the environment" (52 Cal.App.4th at 1207). In other words, the issues raised in the Sunshine Canyon Landfill Expansion EIR represent the type of "unusual situation" that justifies the extension sought by Council Member Bernson, over and above the fact that the EIR is "difficult to review" (as your letter acknowledges). Under these circumstances, it is vitally important that the public have a meaningful opportunity to submit comments on the landfill expansion--an opportunity that will be denied if the public is not given sufficient time to analyze and respond to the highly technical assertions made in the City DEIR. Accordingly, we request that you reconsider your decision and extend the comment period for the full 90 days as Council Member Bernson has requested.

Sincerely,

Mary Edwards

Sylmar, California 91342

RE: Sunshine Canyon Landfill Draft Subsequent Environmental Impact Report
SEIR No. 91-0377 ZC/GPA - Notice of Termination

Dear Mr. Aidukas,

This letter is to inform you that the above referenced EIR file is terminated and effective after the date of this notice. A previous termination warning letter, dated August 1, 1995, to the environmental consultant, Ultrasystems Environmental Incorporated (Ultrasystems), stated that if the revisions made by the Environmental Review Section (ERS) of the Planning Department were not incorporated into the above-referenced draft environmental document, the EIR file would be terminated. After careful review of the re-submitted document by the Planning Department, it was determined that the data base failed to incorporate the requested corrections, and therefore, remained inadequate with regards to CEQA compliance..

It should be noted subsequent to the Scoping Session held on April 13, 1995, ERS staff has engaged in continuous communication with Ultrasystems providing guidance and specific written instruction. A meeting was held on July 18, 1995 with Ultrasystems to discuss the concerns ERS staff had regarding the data base submitted on June 19, 1995. The overall concern ERS staff had was that the document created a false sense of urgency which avoided a careful analysis of alternatives to the Sunshine Canyon Landfill. In that, the data base was inclined to advocate for the proposed project by stating that all other alternatives had greater impacts than the proposed landfill. Further, ERS staff instructed that these other alternatives were to be objectively and seriously considered, and analyzed. The results of these analyses need to be

DRAFT

quantitatively substantiated. Less damaging alternatives to the environment, as well as to the local residents, need to be developed. All these instructions were ignored and not reflected in the September 29, 1995 data base submitted by Ultrasystems.

Annotated portions of the data base were returned to Ultrasystems, with correspondence, dated July 19, 1995 following the meeting of July 18, 1995. The correspondence re-emphasized in detail the concerns of the ERS staff. A project suspension warning letter, dated and effective August 1, 1995, warned of project termination if ERS staff requests were not met by October 1, 1995.

Further correspondence to Ultrasystems, dated August 16 and September 12, 1995, from ERS staff again emphasized in detail the necessary corrections and provided further clarification of alternatives. ERS staff held a meeting on September 8, 1995 specifically regarding 1) No Project alternative, and 2) regional environmental impacts. It should be noted that Chris Funk, the applicant's legal representative, at the above-mentioned September 8, 1995 meeting with ERS staff, made a specific request that regional environmental impacts in relation to the proposed project be discussed in the data base.

ERS staff was in anticipation of receiving a data base incorporating the requested corrections. However, the re-submitted data base #1, received on September 29, 1995, failed to incorporate the necessary revisions. Staff's comments and corrections are attached to this letter for the subject data base #1 submitted on September 29, 1995.

As part of the Planning Department's EIR file termination process, the applicant would have to pay the applicable new fees for further review of Sunshine Canyon Landfill EIR data base. Per Ordinance No. 1905A9 of the Municipal Code, said data base will also be subject to full cost recovery surcharge. In addition, a scoping session would be required.

Should you have any questions regarding this matter please feel free to contact me at (213) 580-5555.

warning

As part of the Planning Department's EIR file termination process, the applicant would have to pay the applicable

the Sunshine Canyon Landfill EIR database.
Per Ordinance No. 1905.4 of the Municipal Code, said database will also be subject to a full cost recovery surcharge.

ZONE PLANS AND POLICIES

RECEIVED
CITY OF LOS ANGELES
DEC 05 1997
ENVIRONMENTAL
UNIT

For many of us who attended hearings and provided comments to the Granada Hills-Knollwood District plan, the current proposal to remove hundreds of acres of land designated as "open space" and to redesignate it as "heavy industrial" seems to be in direct conflict with the goals and policies that we helped draft as a guide for the development of our community. 1274

One of the adopted objectives of the plan was "to encourage open space for recreation uses and to promote the preservation of views, natural character and topography of mountainous parts of the district for the enjoyment of both local residents and persons throughout the Los Angeles region." 1275

This resolve is repeated again as a stated objective "To encourage open space for recreation uses, and to promote the preservation of views, natural character and topography of mountainous parts of the District..."

In the Policy Statements we find the "conservation of open space" as a stated goal. 1276

We feel that the proposed landfill, that will remove hundreds of acres of open space from the Community Plan, is in direct conflict with the goals and policies of that plan, and a betrayal of the efforts of the community that prepared it. 1277

BUFFER ZONE

The Granada Hills-Knollwood Plan calls for the "separation of incompatible uses and more particularly residential from industrial." 1278

A covenant agreement, executed 17 February 1958 under Civil Code section 1468, precludes the owner from using or permitting the buffer zone to be used "for or in connection with said cut and fill dumping operations or for any noxious or dangerous trade or business." 1279

This would preclude the uses that are allowed in the M-3 zone. The applicant is now requesting a change of zone. 1280

Why is the applicant allowed to use this area for a condensate treatment facility? The covenant on this land states: "... their successors and assigns will not use, nor permit the use of any of the following described portions of said lot 8" (similar wording for a portion of lot 9) "of tract 10422 for or in connection with a cut and fill garbage or rubbish disposal operation or in connection with any noxious or dangerous trade or business." 1281

Surely this is an operation in "connection" with the disposal operation. 1282

The SEIR refers to: *"a 100-acre permanent open space buffer from the nearest residential area to the south."* Mr. Funk also makes reference the open space buffer zone that separates the dump from the homes in his testimony. 1283

In reality, the buffer zone itself is nothing more than an oil and gas production area with many active wells and storage tanks. Tanker trucks service this area on a regular basis. At times, enormous drilling rigs have been erected that light up the night sky for weeks while new oil exploration is in progress. 1284 In addition, this area illegally contains the condensate treatment plant that treats the toxic gas condensate before discharge into the sewer. 1285 This area also has an unsightly communications tower. 1286

The buffer zone was once described by Mr. Wise, BFI's site manager, as: *"a green belt buffer zone to isolate the landfill .... .covered with natural vegetation and will never be developed."* This was an obvious misrepresentation. The Buffer zone is, for the most part, a vertical slope; the rest has been leased with no thought to the environment or the residential character of the neighborhood. 1287

We are bitter that greed, alone, has dictated the destruction of this area and that BFI is allowed to refer to it as a *mitigation*. 1288 We need to have BFI purchase the property between Sesnon and the buffer zone, to buffer us from the current activities in the buffer zone. Will this be done? 1289

Under no circumstances should the buffer zone be allowed an M-3 designation, which would allow the most undesirable uses of this area adjacent to a residential community. 1290

Miller

AGREEMENT

(Civil Code Section 1468)

THIS AGREEMENT made and entered into this 17th day of February, 1958, by and between SUNSHINE CANYON, INC., a California corporation, and NORTH VALLEY LAND DEVELOPMENT CORPORATION, a California corporation (hereinafter referred to as "First Parties"), and JOHN O'MELVENY and CORINNE E. O'MELVENY (hereinafter referred to as "Second Parties"), and SAINT VINCENT de PAUL SOCIETY OF LOS ANGELES, CALIFORNIA, a charitable religious corporation (hereinafter referred to as "Third Party"),

W I T N E S S E T H that:

WHEREAS, Sunshine Canyon, Inc. is the owner and North Valley Land Development Corporation is the lessee of that certain real property in the City of Los Angeles, County of Los Angeles, State of California, described as follows:

> Lot 9 of Tract 10422, as shown in Book 157 at pages 38 to 44 of Maps, Official Records of the County of Los Angeles, State of California,

and;

WHEREAS, Second Parties are the owners in joint tenancy of that certain real property in the City of Los Angeles, County of Los Angeles, State of California, described as follows:

> Lot 8 of Tract 10422, as shown in Book 157 at pages 38 to 44 of Maps, Official Records of the County of Los Angeles, State of California,

and,

RECEIVED
CITY OF LOS ANGELES
FEB 27 1958
ZONING ADMINISTRATOR

WHEREAS, Third Party is the owner of those portions of the Southeast quarter of Section 25, and of the Northeast quarter of Section 36, in Township 3 North, Range 16 West, in the Rancho Ex-Mission de San Fernando, in the City of Los Angeles, County of Los Angeles, State of California, described as follows:

> Beginning at a 2 inch pipe in the west line of the northeast quarter of said Section 36, distant South 96.32 feet from the NW corner of said NE-1/4; thence North 2° 28' East, 60 feet; thence North 5° 30' East, 60 feet; thence North 10° 50' East, 60 feet; thence North 29° 38' East, 60 feet; thence North 38° 19' 30" East, 59 feet; thence North 41° 05' 50" East, 631.36 feet; thence South 41° 57' 10" East, 122.55 feet; thence South 72° 25' 40" East, 53.25 feet; thence North 77° 33' 20" East, 271.24 feet; thence North 62° 44' 50" East, 141.76 feet; thence North 81° 11' 20" East, 149.02 feet; thence South 85° 57' 30" East, 108.02 feet; thence North 78° 24' 45" East, 57.78 feet; thence North 62° 47' East, 186.63 feet; thence North 27° 43' 45" West, 590.20 feet; thence North 41° 48' 30" West, 552.63 feet; thence North 12° 33' 45" East, 943.09 feet to a point in the north line of said southeast quarter of Section 25, distant east 1064 feet from the northwest corner of said southeast quarter; thence, along said north line, being also the south line of lot 9, of Tract No. 10422, as per map recorded in book 157 pages 38 et seq. of Maps, in the office of the county recorder of said county, west 1064 feet to said northwest corner; thence, along the west lines of the southeast quarter of Section 25, and the northeast quarter of Section 36, being also the easterly boundary of lot 8, of said Tract No. 10422, South 2736.23 feet to the point of beginning,

and;

WHEREAS, First Parties have made application to the City of Los Angeles, State of California, for a zone variance which if granted will permit the use of a portion of said Lot 9 for a cut-and-fill garbage and rubbish disposal dump; and

WHEREAS, such use of said Lot 9 will not be injurious to the property of Second Parties or of Third Party

hereinabove described provided that no such use is made of the portion of said Lot 9 described as follows:

> That Portion of Lot 9, Tract No. 10422, in the City of and County of Los Angeles, State of California, as per map recorded in Book 157, pages 38 to 44 of Maps, Records of said County, described as follows:
>
> Beginning at the most Southeasterly corner of said Lot, said point being the most Southerly and Easterly boundary of said lot, Thence along the Southerly boundary thereof; North 89 degrees 35 minutes and 02 seconds West 2,639.70 feet to an angle point therein, Thence along the Southwesterly boundary of said Lot North 26 degrees, 05 minutes and 30 seconds West 1,436.76 feet, Thence North 72 degrees 58 minutes and 40 seconds East, 991.19 feet, Thence South 81 degrees 06 minutes and 42 seconds East 1,443.51 feet, Thence North 2 degrees, 16 minutes and 06 seconds West 782.35 feet, Thence North 67 degrees 46 minutes and 40 seconds East 1,012.24 feet to the Easterly corner of said lot, Thence South 0 degrees 24 minutes and 57 seconds West 2,541.19 along the Easterly boundary of said Lot to a point of beginning.

and;

WHEREAS, First Parties have assured Second and Third Parties that they do not intend to and will not use or permit the use of said portion of Lot 9 hereinabove described for or in connection with said cut-and-fill dumping operations, or for any noxious or dangerous trade or business; and

WHEREAS, Second Parties have assured First and Third Parties that they will not use or permit the use for a cut-and-fill dumping operation or for any noxious or dangerous trade or business of that portion of said Lot 8 described as follows:

> Beginning at the most northerly corner of said lot; thence along the boundary line of said lot 8, South 61° 35' 40" East, 862.09 feet; thence East 600.00 feet; thence South 65° 02' 57" East, 1167.75 feet; thence South 11° 40' East, 320.00 feet; thence North 78° 17' 09" East 546.15 feet; thence South 86° 00' East, 345.00 feet; thence South 26° 05' 30" East 1436.76 feet; thence South 0° 25' West 672.15 feet; thence leaving the easterly boundary of said lot 8, North 26° 05' 30" West 1885.36 feet; thence North 86° 00' West 130.71 feet; thence South 78° 17' 09"

West 805.00 feet; thence North 11° 40' West 469.42 feet; thence North 65° 02' 57" West 950.55 feet; thence West 609.56 feet; thence North 61° 35' 40" West 1043.17 feet to the northwesterly line of said lot 8; thence North 47° 43' 16" East along said northwesterly line to the point of beginning.

and;

WHEREAS, the use of any or all of that portion of Lot 9 hereinabove described or of any or all of that portion of Lot 8 hereinabove described for a cut-and-fill disposal operation would be injurious to First, Second and Third Parties and to their lands hereinabove described,

NOW, THEREFORE, in consideration of the foregoing and of the covenants hereinafter set forth, it is agreed as follows:

1. First Parties agree for themselves and their successors and assigns, and for the express benefit of Second and Third Parties and their successors and assigns and for the express benefit of the lands of Second and Third Parties hereinabove described, that First Parties will not, and their successors and assigns will not, use nor permit the use of any of the following described portion of said Lot 9 of Tract 10422 for or in connection with a cut-and-fill garbage or rubbish disposal operation or for or in connection with any noxious or dangerous trade or business:

That Portion of Lot 9, Tract No. 10422, in the City of and County of Los Angeles, State of California, as per map recorded in Book 157, pages 38 to 44 of Maps, Records of said County, described as follows:

Beginning at the most Southeasterly corner of said Lot, said point being the most Southerly and Easterly boundary of said lot, Thence along the Southerly boundary thereof; North 89 degrees

35 minutes and 02 seconds West 2,639.70 feet to an angle point therein, thence along the Southwesterly boundary of said Lot North 26 degrees, 05 minutes and 30 seconds West 1,436.76 feet, Thence North 72 degrees 58 minutes and 40 seconds East, 991.19 feet, Thence South 81 degrees 06 minutes and 42 seconds East 1,443.51 feet, Thence North 2 degrees, 16 minutes and 06 seconds West 782.35 feet, Thence North 67 degrees 46 minutes and 40 seconds East 1,012.24 feet to the Easterly corner of said lot, Thence South 0 degrees 24 minutes and 57 seconds West 2,541.19 along the Easterly boundary of said Lot to a point of beginning,

provided, however, the use of said premises for or in connection with the drilling for or production of oil or gas or other hydrocarbon substances shall not be deemed to be a use for a noxious or dangerous trade or business.

2. Second Parties agree for themselves and their successors and assigns, and for the express benefit of First and Third Parties and their successors and assigns and for the express benefit of the lands of First and Third Parties hereinabove described, that Second Parties will not, and their successors and assigns will not, use nor permit the use of any of the following described portion of said Lot 8 of Tract 10422 for or in connection with a cut-and-fill garbage or rubbish disposal operation or for or in connection with any noxious or dangerous trade or business:

Beginning at the most northerly corner of said lot; thence along the boundary line of said lot 8, South 61° 35' 40" East, 862.09 feet; thence East 600.00 feet; thence South 65° 02' 57" East, 1167.75 feet; thence South 11° 40' East, 320.00 feet; thence North 78° 17' 09" East 546.15 feet; thence South 86° 00' East, 345.00 feet; thence South 26° 05' 30" East 1436.76 feet; thence South 0° 25' West 672.15 feet; thence leaving the easterly boundary of said lot 8, North 26° 05' 30" West 1805.36 feet; thence North 86° 00' West 130.71 feet; thence South 78° 17' 09" West 805.00 feet;

thence North 11° 40' West 469.42 feet; thence North 65° 02' 57" West 950.55 feet; thence West 609.56 feet; thence North 61° 35' 40" West 1043.17 feet to the northwesterly line of said lot 8; thence North 47° 43' 16" East along said northwesterly line to the point of beginning;

provided, however, the use of said premises for or in connection with the drilling for or production of oil or gas or other hydrocarbon substances shall not be deemed to be a use for a noxious or dangerous trade or business.

3. The provisions hereof shall be binding upon and inure to the benefit of each of the parties hereto and their respective successors and assigns, and the covenants of First Parties herein are expressly declared to be for the benefit of the lands of Second and Third Parties, and the covenants of Second Parties herein are expressly declared to be for the benefit of the lands of First and Third Parties.

IN WITNESS WHEREOF, Second Parties have executed this agreement, and First and Third Parties have caused this agreement to be executed on the day and year first above written.

THIRD PARTY

The Dumps Zoning History

* The dump started as an illegal operation in the mid fifties when the objection of neighbors forced the operators to legalize their facility. The North Valley Land Corporation made application for a CUP in 1957. Certain actions by the proponents in the notification process were irregular and "fraudulent" according to John O'Melveny, founder of O'Melveny and Meyers and himself owner of a large ranch. (please see attached letter). 1291

* The City Planning Commission on June 5,1957 DISAPPROVED the application for a CUP stating, in part, that "The proposed M3 zone would actually constitute a license to utilize the property for numerous obnoxious uses because of the unrestricted nature of the zone classification." (see attached findings). 1292

* In the Commission report, the Air Pollution Control District stated prophetically: "We believe that the location of an area of M3 zoning in this vicinity would have highly adverse effects upon large portions of the San Fernando Valley from the standpoint of air pollution, and hence, is not desirable." 1293

* The matter was appealed to Council and the report of the Planning Commission upheld. 1294

* The Planning Commission suggested the applicant seek a zone variance, rather than a zone change. This was done and in 1958, under ZA case 14544, the variance was granted over the objection of neighbors living directly across from the project for a period of ten years. 1295

* Condition 20 of that variance reads: "That, at the expiration of this grant the premises shall be left in a neat and orderly manner with no uncovered materials or waste products on the premises, and shall be maintained in a park like appearance. Further, that upon completion of the landfill reclamation project, the property involved be made available to the City or County Department of Recreation and Parks for possible recreational purposes, if found desirable for such purposes, or if the property is used, it be devoted to permitted agricultural uses or some private recreational use if approved." 1296

* In 1961 the owners returned to request a modification of the zone variance to include accepting wrapped garbage collected by the City and not allowed under the conditions of the existing variance. This condition was granted, however the report that accompanies the variance request (ZA case 15925) notes: "Inspection of the records and property discloses that numerous conditions involving the methods of operations have not been complied with." 1297

* In 1966 the operator applied for and was granted variance. From the testimony of the Zoning Administrator on May 17, 1966 at the appeals hearing (page 32 BZA case 1672) we learn that the early application for an expanded site was due to the fact that the operators had exceeded their permitted elevations. 1298

* Pages of testimony related to the hardships experienced by the residents living directly across from the landfill exist in this record. 1299

* In testimony at the ZA hearing on October 29.1965 the proponent testified that "when the fill has been completed a golf course or recreational area is proposed on portions of the filled area" 1300

* One of the conditions of this variance (17804 #14 issued April 18, 1966) reads: ".... Further upon completion of the project the applicant or owners shall advise the City and County Recreation and Parks Department that the property is available for recreational purposes." 1301

* Although the aggrieved residents living across the street from the site vigorously protested, the dump was issued a 25 year variance. The City ignored their complaints of odors, dust and litter and promised them a valuable recreational area in 25 years. This residential community was gradually replaced by mixed industry and salvage operations. 1302

* In 1978 BFI bought out the smaller dump and began taking far more trash than the amount indicated in their operating permit (3000cyd) and violated the operating hours, set forth on the permit. BFI exceeded their elevations and went beyond their boundaries into the Significant Ecological Area, In so doing, they removed an oak woodlands, again without a permit. BFI encroached into the primary watercourse with trash and compromised federally protected wetlands. 1303 1304

* In 1988, because of these violations and in response to the many complaints from residents living near the landfill, Councilman Bernson filed a revocation action. 1305

At the hearing scores of aggrieved residents told about their experience with blowing dust trash in their trees and parks and foul odors that clung in their entries. 1306 The Zoning Administrator ruled in a decision, dated September 1, 1988, that the landfill had violated its permit in the following ways: 1307

* The landfill was causing conditions that were MATERIALLY DETRIMENTAL to the surrounding community. 1308

* The landfill had exceeded its proscribed elevations. 1309

* The landfill had placed its haul road and trash beyond the variance line.

* The landfill had come too close to the water course and Bradley Ave.

* The landfill was operating too close to the ridgeline.

* Through the ZA's ruling and in the appeal process new conditions were added to the permit, in an attempt to cure the violations and BFI was ordered to request a curative variance (the only one ever given by the City) to encompass the land that they had illegally used. In addition, BFI was ordered to move operations to a canyon further from the residential area nearer the I-5 freeway. The violations were upheld through appeals to City Council and BFI significantly reduced the amount of trash taken in the two year period that proceeded the dumps closure with the expiration of their variance in 1991.

* Many of the mitigations ordered by the zoning administrator were not complied with, so that, when the variance expired, BFI could walk away from them. Some of these important conditions were:

* The health study, ordered by John Parker in the Revocation Findings, Sept 1, 1988.

* Restoration of the water course, ordered under ZA case 17804 (PAD) Nov. 2, 1988, Condition 2 c.

* Replacing oaks in the north canyon, ordered under BZA case #4336 & 4337.

* Hiring an inspector to oversee closure, BZA case 4484, Dec. 19, 1991, Condition #2.

* Providing an accurate survey, ZA89-1129.

* Offering the land to the Dept.of Parks and Recreation, ZA case 17804.

IN REPLY REFER TO

Councilman Ernest E. Debs
Room 132-a City Hall
Los Angeles, California

Dear Mr. Debs:

I am writing to you concerning my ranch in the San Fernando area, which is in the City of Los Angeles. The description of the ranch is as follows:

> "Parcel 1. Lots 7 and 8 of Tract No. 10422, in the City of Los Angeles, County of Los Angeles, State of California, as per map recorded in Book 157 Page 38 et seq. of Maps, in the office of the County Recorder of said County, together with the right and easement to use for road purposes the existing road across the Northerly 600 feet of the Easterly 1300 feet of Lot 5 of said Tract No. 10422."

There is also additional property in the bottomlands of around 50 or 60 acres, which may be described by metes and bounds, but it is generally property fronting on Balboa Avenue, at 13101 Balboa Avenue.

I have owned this ranch for over 19 years. I have spent every weekend on it that I possibly could, and my family enjoy it thoroughly, including my children and grandchildren. It is very dear to our hearts. I have spent a great deal of money on it, and it has become a very important part of our lives. It has a tremendous potential value as residential property, and the sub-dividers are now putting in housing projects, a country club, etc., within 3/4 of a mile of our front gate.

The ranch is comprised of around 1,000 acres, if measured as a flat property, but it is, of course, quite hilly, and there is probably twice as much grazing land on it. We raise cattle and grapefruit on it at the present time, but its real value is as possible residential property in the future. For instance, 72 acres immediately

adjoining me, of hilly, rolling country, could have been purchased by me 15 years ago for $12,000. It was sold by Mr. Welsh for $45,000 eventually, was purchased some years ago for $125,000 and is now on the market for $350,000. This gives you some idea of what property values are in that portion of the City. The entire ranch lies within the City limits of Los Angeles.

Directly adjoining me is Bob Hope's property, directly adjoining him is about 15 acres belonging to James Cagney, and on the east side of the property the Roman Catholic Church owns about 100 acres which is being used as a camp for underprivileged boys. It formerly was owned by Gene Autry, and it has beautiful buildings, a swimming pool, baseball field, etc.

Immediately across Balboa from us, and adjoining the Church property, is property owned by the Vangle brothers, which is largely devoted now to raising citrus. A large piece of property, probably 600 or 700 acres, which adjoins the Vangle property, the Catholic Church property and my own land, was purchased some time ago by a Mr. Visco, who operates under the name of Bentz Disposal, and has made application for a zone change under the name of North Valley Land Development Corporation. This man is in the rubbish collecting business and is attempting to zone the property so he can dump rubbish on it. There have apparently been two hearings before the City Planning Commission, and his last hearing was denied last week by the Planning Commission on the theory that the property surrounding it was potential residential property in the future, which is true, in my opinion. Neither the Vangle brothers nor the Catholic Church, nor myself, or anybody that I know in our neighborhood ever received any notice of these hearings. The law, of course, is that he has to notify everyone who owns land within 300 feet of his boundary line. My people, on investigating the matter, have apparently found that what he has done is to cut off a segment of his property on all sides 300 feet back, and conveyed it to people over which he has complete control, so that the only people who are notified of these hearings are his own stooges. I am having this entire matter checked by the Title Insurance and Trust Company, so as to obtain their names. I assume that he will now appeal from the decision of the Planning Commission to the City Council, but of course none of us have any way of knowing whether such an appeal is taken unless we get a notice, and presumably we will have no notice.

#3 - Councilman Ernest E. Debs - 6-17-57

I wish to get this letter on file with you people and a copy of it on file with the City Planning Commission for whatever protection it will give me. I am going to organize a group of property holders out there, including all the people I have mentioned above, and a great many others, to fight this thing for all that we can put into it.

From what we have discovered, this man is apparently doing this in an entirely fraudulent way for the purpose of preventing any of us from knowing that he is attempting to zone the property for the purpose of dumping rubbish on it.

I understand that you are going to have a meeting on Wednesday of this week, and I hasten to send this letter to you, and I will get any and all other information that is necessary which you desire. If this man seeks to appeal from the order of the City Planning Commission, I would certainly appreciate it if I could have notice of this appeal and an opportunity to appear before you or the City Council, whichever is necessary, to explain our position.

Sincerely yours,

John O'Melveny

North Valley Land Development Corp. City Plan Case No. 8246
c/o Reuben Rosensweig, Attorney
Suite 1203 Bankers Building
629 South Hill Street
Los Angeles 14, California

Attention: Hy Ginsberg

Gentlemen:

The City Planning Commission, on June 6, 1957, disapproved your request for a change of zone from Zone A1 to Zone M3 on an L-shaped parcel of land having a frontage of approximately 175 feet and an over-all depth of 2000 feet lying on the southwesterly side of San Fernando Road 1665 feet southerly of Ferncliff Court in the Sylmar District.

Although the applicant was legally represented at the time of public hearing, no attempt was made to make any strong and conclusive showing to support the change of zone as requested. While the records support the applicant's statement that this property lies within an oil drilling district, the wells are not visible from the property in question, and indications are that wells within this district are on extremely low production and might be abandoned at any time in the near future.

The Commission was of the opinion that there are no factors which could justify approval of the establishment of the proposed M3 district based upon considerations of public necessity, good zoning practice, or in the interests of public welfare or convenience. The proposed M3 Zone would actually constitute a license to utilize the property for numerous obnoxious uses because of the unrestricted nature of the zone classification. The area in question appears to have been designed without consideration of topographic conditions.

Staff recommendation to the Commission in this matter should not be construed as approval or disapproval of a land reclamation project on the property in question since such a request should be filed with the Zoning Administrator's Office as a variance to the present zoning regulations if such a use is so desired.

The zoning regulations provide that any person whose property is included in a proposed change of zone may appeal to the City Council from the disapproval by the Commission of the requested change. The appeal must be filed in duplicate with the City Clerk, Room 195, City Hall, within twenty days from the date of mailing this notice. It must set forth specifically wherein the Commission's findings and decision were in error, and that public necessity, convenience, general welfare or good zoning practice justify the requested zone change.

Very truly yours,

John E. Roberts
Director of Planning

MAYOR

...INQUIRIES
...TO THIS MATTER,
...O FILE NO.

79905

December 23, 1957

City Planning Commission

North Valley Land Development Company
c/o Jerome Weber
Suite 1203 Bankers Building
629 South Hill Street
Los Angeles 14, California

Greetings:

At the meeting of the Council held December 23, 1957, the following report of the Planning Committee was adopted:

"The City Planning Commission transmits report relative to appeal of the, North Valley Land Development Company from disapproval of request for a change of zone from A1 to M3 on 41.9 acres of land on the southwesterly side of San Fernando Road, 1665 feet southerly of Ferncliff Court. CPC 8246

The Commission disapproved this request for the reasons more fully set forth in their attached report dated July 9, 1957, and because it felt that a land reclamation project on the property in question should more properly be filed with the Zoning Administrator's Office as a variance.

On August 7, 1957, your Committee conducted a public hearing on this case at which time all interested persons present were given an opportunity to express their views, and after discussion, the matter was taken under advisement.

We are aware of a recent State Law relative to the approval of public dump sites; however, since it is proposed to operate a private dump on this property, we feel that the Zone Variance method should be utilized in order that the necessary regulatory conditions may be applied.

Your Committee is now advised that the applicant proposes to file a zone variance application with the Zoning Administrator requesting permission to use the subject property for a land reclamation project. Accordingly, we concur in the action of the Planning Commission and RECOMMEND that said appeal be denied without prejudice, and thereafter the matter be filed."

Respectfully yours,

City Clerk

INTRODUCTION

The community's efforts to properly respond to this confusing SEIR have been frustrated by incomplete and misleading information. 1323

In the first place, the quantity of waste that would be permitted to enter the landfill daily is never accurately discussed. 1324 The lack of this information makes it impossible to accurately access the important traffic impacts, and air quality impacts. 1325 The proponent currently has a State-issued Solid Waste Facilities Permit (see attached) to accept 9000tpd. This permit gives a top daily limit of 6,600 of buried waste and the additional is made up of exempt waste. Whatever this waste is comprised of, the fact remains that 9000tpd can currently enter without any additional permits. If then, the proponent is requesting a permit from the City to receive an additional 5,500tpd, the possible total could be 14,500tpd. This is a huge difference from the 11,000tpd mentioned so often in the SEIR. 1326 We realize that weekly averages are somewhat lower, due to lack of commercial inflow on Saturday, but the real possibility exists that weekday inflow could regularly reach 14,500tpd. 1327

Secondly, we find that the changes that are seemingly occurring between the County EIR and the City SEIR are never made clear. 1328 Since the information in all volumes is included by reference, you would expect it to agree on specifics. 1329 In one place it states that oak trees will be monitored for three years; in another place it says five. 1330 In one place it says graded slopes will be 1.5 to 1, or 2 to 1; in another it says 3 to 1. 1331 In one place in these documents we are told that final cover will be 15 feet deep, and in another we are told it will be three feet deep. 1332 In several places are told the working face will be kept to a small 3 to 5 acres in area, and then we are told that it will reach 10 acres in another section of the SEIR.

These are just a few of the discrepancies. The proponents need to list the changes they propose for the City landfill. 1333 The public cannot possibly know what they are proposing without this information.

Thirdly the information is hopelessly outdated. We attempted to contact one of the two Doctors, who were quoted as having said that a health survey was unneeded. We found that he had apparently commented five years ago, and had left the County employ several years ago. 1334 The other doctor who was quoted said he knew nothing about the project and could only comment on the difficulties involved in doing cancer studies. 1335 Neither of these doctors

5. The facility shall not accept more than 9,000 tons of solid waste (Exempt Waste [See Finding 1.F. for the definition of Exempt Waste] plus Refuse. This figure, for the purposes of this permit, will be referred to as the Gross Tonnage Limit.) on any operating day until such time as the operator has constructed traffic improvements pursuant to Condition No. 13 of the CUP and has submitted, to the LEA, a document from the City of Los Angeles, as an addendum to the RDSI, which states:

   a. The daily Gross Tonnage which the facility may accept with the traffic improvements;
   OR
   b. The daily maximum number of vehicles which, with the traffic improvements, may enter the facility.

   If this document contains only references to the maximum number of vehicles, the LEA, using industry standards, shall translate this figure to daily tonnage.

   The resultant tonnage, derived from either a. or b. above, will be the Gross Tonnage Limit but in no case shall exceed 17,500 tons/day. (Refer to Page 30 of the MMIS, Attachment 1)

6. The final elevation of the filled area, including final cover (and surcharge) shall not exceed 1885 feet above mean sea level.

7. The operator shall install (prior to landfilling operations) and operate Three (3) Scales in order to weigh all waste received at the facility.

8. One of the Three (3) Scales shall be used only to weigh:

   a. exempt waste as it enters the facility;
   b. waste leaving the facility which will be recycled/diverted or put to further use;
   c. waste which initially was classified as exempt upon entering the facility but later determined to be refuse.

9. The operator shall maintain a strict accounting of the amounts and types of exempt waste which enters the County site and recyclable or reusable waste which leaves the County site or is reused on site.

could have been aware five years ago of many studies that now show the grave impact pm10's and diesel-generated particulates have on human health. Inclusion of this sort of dated material has no substance. Since health issues were identified as an important issue to the community, this section needs to be completely redone, analyzing the effects of these emissions on health. Traffic, housing, demographics and many other areas are similarly outdated. 1336 1337

THE CITY'S RESPONSIBILITY

Even though it is obvious that BFI's hired consultant prepared this document, the City must share some of the responsibility for this disorganized and inaccurate SEIR. 1338
We implore the City to independently run the modeling programs to check their accuracy. The community does not have the capability to verify the results and assumptions. 1339
Instead of meeting with BFI's hire consultants, and being smoozed into accepting their biased interpretations, it is incumbent upon the City to independently review this SEIR and give it the highest level of scrutiny. A project this large and complex deserves nothing less. 1340

1.6.5

If BFI was offered extension after extension in the preparation of this SEIR, why was the public's request for an additional 180 days for response refused? The public is at a considerable disadvantage. They are presented with two huge disorganized volumes, and referred to over a dozen more volumes, and forced to review them at libraries after work, or on Saturdays. 1341 1342

5.9.5

We are concerned about the possible use of ADCM's. We believe that they will not be sufficient to control surface gas omissions. This section states: "Well-compacted soil is still regarded as the superior daily cover material because of its ability to retard odors and reduce vector intrusion." 1343 1344

In view of this, will soil then be the cover material used on this project?

2.15.1
END USE OF SITE

It was always the intention of those who granted the original variance to have the land used for recreational purposes when the dump closed its doors. Since BFI seems to now feel that this is too dangerous, and the project will not to be complete for thirty years, the public will again wait. The thirty years began in 1991 and by 2021 nature will have reclaimed it and our grandchildren will again have open space. But we must have BFI's assurance that this will happen. The County states in its Findings that: "The Project site will ultimately provide additional permanent open space for the County when the landfill has reached final capacity and the facilities closure plan is completed. The completed landfill surface will be revegetated with substantial trees and vegetation as described in the FEIR Response to Comments Volume A Topical response 15) The site will be maintained by the permittee until the time that its final use is determined by State and County, however it is expected that ultimately it will be made available to the public at no additional cost to the agency designated to receive the land." 1345 1346

Do we have BFI's assurance that they will turn the City site over to the City at no additional cost?

Why is the land that is to be dedicated in upper Bee canyon not shown or mentioned? This purchase is required under the County C.U.P. 1347 1348

ALTERNATIVES

Although a viable alternative with a projected capacity of 70 million tons exists in the County, the SEIR does not include a full discussion of a County-only alternative. 1349

The conclusions drawn from both the no-project and reduced volume alternatives do not recognize that either choice would, in all likelihood, lead to a 70 million expansion in the County. The County findings clearly allow BFI to make that application. In this case all the arguments about the negative aspects of transporting waste or loosing County bucks are moot. I'm intrigued by the argument that if the project was approved in a reduced form, dust and "litter generation would occur at these other facilities." This creative little jewel is at least good for a laugh in the midst of this depressing cross between *Mine Kampf* and *The Prince*. 1350 1351

The only substantive issue in a County expansion would be the loss of biota. This would amount to 799 additional oaks (1363, minus the 564 saved in the City) When we inquired of Mr.Richard Fraser, then with the County Regional Planning Dept. at the time of the County zone changes, as to the reason the whole 70+ acres were being removed from the SEA designation, rather than just the footprint, Mr.Fraser said that the whole area would be severely impacted by the landfill operations, particularly since the main stream that fed the canyon was being graded to bedrock. 1352 1353

Where is the analysis of the map presented in 1991 (attached)? This map was represented to be the City expansion proposal and made part of the County EIR. We can only believe that it was not submitted, in the belief that, since the City would probably cut back the configuration, it represents what the proponent sees as a fall-back position. 1354

The County requested that BFI seek a minimum expansion of 20 million capacity. Why is BFI seeking so much more? 1355

Page 1-14 & 5.9 Alternative Waste Management Technologies & Strategies. 1356

Anything that would reduce the amount of trash going into landfills must be given careful evaluation. We believe you have dismissed these options too lightly The City has issued an RFP for new and innovative technology projects. 1357

Why were no inert landfills included in the study? Couldn't directing all inert loads to these facilities reduce the need for class III landfills? 1358

WORKING FACE

One of the mitigations offered and repeated, again and again, in these volumes was that the working face was to remain small, 3 to 5 acres. Now this document is talking about an eventual 10 acre working face. This flies in the face of what the community was promised. The smaller working face with the rest receiving either temporary or final revegetation was, and is, an essential part of the mitigation program. 1359

SLOPE GRADIENT

In the County's Finding of Facts we read:
"The final maximum refuse slope gradient at the site will be no steeper than 3 horizontal to 1 vertical for the landfill extension" 1360

Why is a lesser standard, i.e. 1.5 to 1, or 2 to 1 being applied to the City Project?

Figure 2.4.2

Why isn't the land that is currently being acquired in upper Bee canyon shown or discussed? The County directed as follows: "The applicant is further required to arrange for the acquisition as public open space of approximately 450 additional acres along the southwest boundary of the landfill within upper Bee Canyon." What is the status of this acquisition? 1361 1362

I.6.2
Public Scoping Meeting

The public has never had the opportunity to address the SEIR. The scoping meeting was held over five years before the release of this document. It was held on the night of the LA riots, when people were being cautioned to stay at home. Only a few ventured out, disregarding the advice broadcast on their radios and TV. This was not a full hearing of the issues. 1363

I.6.3
Post Scoping Meeting

We would assume that City staff met regularly with the consultant and the proponent. What makes this meeting so different? Who on the city staff independently reviewed this document? 1364 1365

MAPS AND GRAPHICS

Elevations on some maps are, for the most part, unreadable. Please correct. 1366

Photographs showing the projected height of landfill in relationship to the existing contours were omitted from this document. The elevations and design have changed since the original DEIR was prepared and those older view sheds are no longer accurate. 1367 1368

No map seems to exist that shows the approved County elevations and how they will connect with the proposed new county acreage and then to the City. The maps attached to the County approvals and the Phase II Stability Report in the appendix are too small to read. We understand the originals have been revised to promote stability. Please provide an updated map. 1369 1370

RECYCLING

The City has embarked on an ambitious program of recycling that is not only meant to satisfy the goals of AB939, but to save precious resources. Siting more landfills that are cheap and close in provides a strong economic incentive for the City to abandon its commitment to recycling to provide short-time savings at the expense of long term solutions. If the City, or other cities, attempt to claim the green waste that is used for daily cover as "recycled" in order to meet the goals of AB939 the recycling effort will be further undermined. Will the City attempt to do this? 1371 1372

Various places in the document give different descriptions of the on-site recycling program. It is, at times, referred to as a composting program (see appendix). The County volumes describe an ambitious program for corrugated materials, wood processing etc. Exactly what will be processed at the facility proposed for the berm? 1373 1374 1375

Why was the facility relocated from the site originally proposed near the I-5 freeway? This type of facility can have significant impacts. Please prepare a separate environmental document for this facility describing, in detail, the process and equipment to be used and dealing with the effects of noise, odor, air pollution etc. upon the residents adjacent to the facility. How close will the nearest residents be to the facility? What do the studies of green waste used as daily cover show in terms of outgassing and other potential problems. 1376 1377 1378 1379

page 4-338

The traffic studies referred to are far to old to be accurate. Will you provide recent ones? The January 1995 counts were not accurate, since San Fernando Road and Foothill were still impacted by the overpass repair taking place following the earthquake the previous year and commuters were choosing alternate routes. The January 1995 mini-study is still more than two years old. 1380 1381 1382

Page 4-372

Please describe exactly which roadways will be "widened," which "reconfigured," and where additional lanes be will provided? Hasn't some of the restriping already been done, as a mitigation for the County project? We need to know exactly which additional mitigations will be done. 1383 1384 1385

If the addition of traffic from the landfill raises the intersection levels to LOS F, why doesn't the City consider that significant? 1386

How many 60 foot transfer trucks could be accommodated on a freeway offramp? If most of the transfer trucks arrive from the south, won't this cause the offramp at Roxford to back up ? 1387 1388

You seem to be using a factor of .64 to figure trucks which you note as being "passenger cars times two." In that case, using a worse case scenario, the 14,500 tpd would generate 9280 truck trips, or 4640 passenger trips. This number is clearly over the level of significance. 1389

Since the SEIR for this project was published less than a year after the opening of the County landfill, it is necessary to evaluate all the traffic impacts of both County and City, or be guilty of seeking incremental approvals in violation of the requirements of CEQA. 1390

page 4-379

You have provided conflicting information about the incidence of accidents in the vicinity of the landfill. On this page you indicate "no unusual safety problems" from your search of records (1982 through 1987). This is in direct conflict with the report to the Regional Planning Commission given by the County Dept.of Public works and contained in Vol.A of the Response to Comments which states: "in addition, the traffic studies indicate a higher than average accident rate at intersections of city streets with current volumes which are 5,000 to 6,000tpd" (1989) In view of this discrepancy, please provide accident figures for the appropriate intersections and the landfill entrance. 1391 1392

Neighbors who use San Fernando Rd. report that the driveway entrance to the landfill is dangerous and has been the scene of several accidents. We don't know if any were serious enough to be reported, but we feel that intersection should have a signal, even if no further expansion is granted. 1393

Have you considered designating the right turns from San Fernando Rd. and Foothill on to Balboa as carpool-only turns at peek hours in the AM, and left turns as carpool-only turns at peek hours in the PM ? This would effectively reduce the dangerous traffic on San Fernando Rd. and encourage carpooling. 1394

BIOTA Section 4.4

We were not able to find the field survey referred to in section 1.4.4 conducted by Dole and Fisher, 1978, covering 1.560 acres. In which referenced volume can we find a copy of that survey? Will you incorporate it into your appendix? 1395 1396

Page 4-187 says that a field survey determined that there was 4.20 acres of wetlands and 5 acres of riparian habitat in the city. Why do you appear to be planning mitigation based on a 2.95 loss? (page4-189) 1397

page 4-188 Impacts Resulting from Closure

According to the staff of the Environmental Affairs Department that is overseeing BFI's closure of the existing City landfill and the staff of the State Integrated Waste Management Board nothing in their requirements, or in engineering practice, necessitates constructing surface water "improvement channels". When we ask the Environmental Affairs staff why this was being done, they said "because BFI wants to." Does the 2.95 acres referred to in the next paragraph include the 1.25 acres that may be removed at closure? 1398 1399

Will the proponent guarantee that the wetlands mitigation will be carried out in the vicinity of the project? 1400

page 4-198

Why is the City requiring only a 3 year monitoring program for the oaks, instead of the 5 year program demanded by the County? 1401

Will the period over which the trees are monitored begin when the tree has reached the required 1 inch in diameter when measured 1 foot above the ground? This is not clear. 1402

Page 4-194 Cumulative Impacts

Will the "phased restoration" be implemented as described by Mr. Osterling in his Revegetation Plan contained in volume A ? 1403

Were any heritage oaks identified in the surveys? The chart in the index shows diameters up to 52 inches. How many of these large oaks were found and how will their loss be mitigated. 1404 1405

The first sentence in paragraph under City Mitigation Measures on page 4-194 that starts "A total of 100---" doesn't make sense. Please clarify. We cannot comment on this reduction until that sentence explained. 1406

Topical Response #14 incorporated by reference on page 4-139 of this DEIR states that the rare big cone fir will be replaced at a five to one ratio and monitored for five years after reaching a diameter of one inch. We feel that this is an acceptable mitigation. 1407

What performance guarantee is being placed on the important mitigation for the Biota? 1408

What field verification of the mitigation program will take place? When will this happen, in relationship to the annual report. Will a forester from a public agency be on hand to verify the accuracy of the field study, as required by the County permit? 1409 1410 1411

The County maps, showing the Significant Ecological areas, show SEA 20 extending into the city. Why is that area not shown on the map presented? Figure 4.4-1 shows this area as greatly disturbed. Since this land was outside of the variance line, as shown on all city maps, please explain why the oak woodlands shown on the vegetation map outside of the variance line was removed? The map prepared by Ultrasystems and labeled number 3, that is a part of the original EIR, shows many communities of oak woodlands in the City and outside of the variance line that now seem to have disappeared. Please explain? Was the City ever compensated for the loss of these oaks under the City Oak tree ordinance? In BZA case 4336 & 4337 Exhibit #B-1 condition #5 which approved the curative variance reads: 1412 1413 1414

> " Oak trees. No oak tree shall be removed from within the area of the variance, except in the northern fill area. Oak trees within that area shall be counted prior to displacement and replaced at a ratio of two trees for every one removed in strict compliance with the oak tree regulations of Section 17.05-R of the Los Angeles Municipal Code." 1415

Why was this never done?

RISKS

4.9.1

Sections of referenced materials should be reprinted and circulated with the current documents. Parts of the EIR were circulated eight years ago and the original volumes are not available at all listed libraries and certainly all referenced material should have been provided to the decision makers. 1416 1417

Will BFI fund half of additional hazardous waste roundups in the City, as it has been required to do in the County? Will it be, at least, in the same ratio, i.e. 6 for each 17,000,000 tons of permitted capacity. 1418

What percentage of HHW generated is being properly disposed of at these roundups? 1419

Based on the City figures of.7% of their waste stream being hazardous, and subtracting what is now being properly disposed of at roundups, how much hazardous waste will eventually be put into the landfill at capacity, using a worst case scenario. 1420

The EIR states that a waste-load inspection will be conducted for every 1000 tons received.
The current County permit requires that 6 waste-load checks be conducted daily, REGARDLESS of the amount of inflow. Why is the City requiring a lesser standard? 1421

A City inspector should be present at, and conduct, all waste-load checks, since very little of the HHW is being found at the current inspections or at the working face. 1422

For example, BFI reported in February of this year an inflow of 58,961+ tons or 117,992,000 pounds, but they recovered through examination of the working face only approximately 115 pounds of prohibited waste. Using City figures 0.7 percent of their waste, or 825,000 pounds, could be expected to be hazardous. 1423

The SEIR refers to "sensors for detecting volatile organic compounds". These sensors are not being used at the scale house and, in fact, have never been used. When we inquired why this was not done, we were told by Mr. Hanson of the County Health Dept. that "it (the detector)" would go off in every load." Why then, if BFI is conducting the required 144 load checks monthly, and monitoring the working face, are they finding only 23 items (as occurred in February) and similarly small numbers in other months? 1424

Has anyone, over the years since BFI first started operating the site in 1978, been fined, or punished in any way for bringing in prohibited waste? When and how? 1425

The SEIR states a "Full time inspectors shall be employed on site for the inspection of waste materials." Will those inspectors will be employed by the City, and the City reimbursed by BFI for his (her) salary, as is the case with the County inspector at the County site? 1426

It is imperative that any inspector not have direct ties with BFI, but be a City employee. 1427

If it takes one full-time inspector to monitor the disposition of Trash in the County trash will at least one full-time inspector more be employed, so that the dump will ultimately have at least two full-time inspectors on site? 1428

The SEIR states on page 4-299 that .."all waste materials brought to the site would be unloaded at an active working face area, compacted with at least 9 inches of clean soil by the end of the working day." This is a departure from County practice and seems to conflict with other portions of this document. 1429

Can we rely on this use of dirt as cover? 1430

The current system of requiring tarping at the present landfill is not working. Many of the smaller trucks that use neighborhood streets and drop litter arrive at the dump without cover of any kind. The landfill workers may issue a "warning," but there is no practical way of keeping track of repeat offenders and thus far no fines have been imposed. We, therefore, recommend that a five dollar additional charge be imposed, similar to that imposed at Puente Hills, on all trucks arriving uncovered and that the revenue from that charge be donated to the beautification of the community in the immediate vicinity of the landfill. 1431 1432

The landfill is now operating in the lower elevations of the canyon and taking far less trash than the daily limit, nevertheless neighbors have complained about trash from the dump in O'Melveny Park. An observation of the on-sight inspector for the current operation reads: "I did observe plastic bags and papers blowing approximately 100 feet but confined within the perimeter of the canyon" How will this be controlled when the dump is operating only 50 feet below the ridgeline, as they propose. 1433 1434

How have the conditions that resulted in two safety violations being issued by OSHA, concerning the death of a worker, been corrected? 1435

Would the citizens advisory committee be funded to conduct health surveys? 1436

Why does this document refer to the incinerators as flares? The community was corrected on this point by the engineers at AQMD. Is this a euphemism intended to make incinerators seem more benign, and mislead the public? 1437 1438

You say that "as an example of how the system operated during the Northridge earthquake on January 17, 1994, the system" (gas collection) "successfully shut down, effectively reducing the risk of upset." Isn't it a bit like saying: "On the morning of the earthquake I was successfully propelled from my bed, thus effectively reducing the risk of dying in bed?" Didn't the incinerators shut down, do to the lack of electrical power, just like everything else in the neighborhood? Has the system had any other shutdowns due to lack of electrical power on other days of high usage? If so, please document. Will you purchase a generator to provide back-up power in emergencies? 1439 1440 1441 1442

The Dept of Water Resources worries (letter to Rodney Nelson, July 1997) that shear strengths, based on an analyses of the OII landfill were not correct because they believe it is probable that the OII landfill had a"higher component of soil in the waste" than other landfills. 1443

Since BFI is not now using soil as daily cover in the County portion, how will that impact shear strength analysis if this practice continues in the City? Did the stability analysis for the City consider this as a factor. 1444 1445

Do you intend to continue to use ADC's? Other parts of this document indicate you will be using soil. If you use an ADC, will you request a change in the CUP to reflect this important operational change. 1446

APPENDIX

The Appendix volume is not paginated and is a hodge podge of relevant and irrelevant information. For example, the spring and stream information should be accompanied by a map showings where the samples were taken. Without this they are meaningless. The obviously less important items like the photo copies of the speakers' cards should not have been interspersed with comments from responding agencies. The reader gets the feeling that the preparer is trying to create an SEIR of such size and so confusing and conflicting in content that the reader will be intimidated. 1447 1448 1449

Many of the resource documents in Appendix are over 5 years old. Will these be updated? 1450

Traffic from the Appendix

The traffic analysis is yet another glaring example of incremental approval being sought by the proponent. By splitting the project into stages the analysis of the impacts of the entire project remain unknown. In less than a year after opening, BFI is back with another proposal to expand. The original document attempted to consider the larger project but when these projections exceeded a level of significance (see Response to Comment Volume A pg.592) traffic calculations were reduced to include only the County portion. Now the County impacts are being excluded. This is clearly an attempt to minimize the impacts of the entire project as required by CEQA. 1451 1452 1453 1454

The County Dept. of Public Works said in their report to the County Regional Planning in 1989: "The traffic studies set forth in the EIR, combined with the lack of a dedicated freeway access, suggest that negative impacts of traffic volumes associated with more than 6000 -10,000 tpd may not be mitigated by the traffic mitigation measures" BFI now has a permit that limits its daily tonnage inflow to 9000 tpd (see SWFP at page 11) and is requesting another 5,500 tpd. This amount clearly is significantly over the tonnage that the County believed would cause negative impacts. 1455 1456

In that same report, the County also stated that: "The traffic studies indicate a higher than average accident rate at intersections of city streets with current volumes which are 5000 to 6000tpd." Since BFI has implemented its traffic improvements and the landfill is currently operating at well under its permitted inflow, please provide the 1997 accident reports identifying the same comparisons used by the County to reach their conclusions. 1457

The Linscott, Law & Greenspan report on traffic does not factor in the exempt waste that is not counted toward tonnage requirements but must be considered in any traffic analysis. They conclude that the 6,600 TPD maximum County plus the 5,500TPD maximum City would result in a 12,100TPD limit. This however is erroneous, since the State issued SWFP for the County allows a gross tonnage of 9000 TPD, including exempt waste. This means that the real impacts should be calculated on the basis of 14,500 TPD. 1458

The LADOT should be required to follow its own guidelines on providing recent traffic data (ie data should not be over two years old). In the Linscott study they say they were allowed to use 1992 and 1993 data and refer to it as 1995 data (page 8). How can this company justify this misleading and unscientific presentation? They go on to say that they base this on the belief that the January 1995 data showed lower volumes at two intersections. Interestingly these areas were still undergoing construction modifications from the 1994 earthquake and data taken at that time could in no way reflect the current impacts. Even the Jan 1995 data exceeded the two year proscription by eight months and it fails to include the traffic generated since the landfill in the county opened in August of 96. Certainly new counts must be made. 1459 1460 1461 1462 1463

We have trouble seeing why the trip generation rates based on the "daily counts taken at the landfill entrance" (page 15) are not more accurate than the speculative estimates provided by BFI. BFI is required to keep daily records of the weight of all trucks entering the landfill. The projections should be based on the actual data. The SEIR states that transfer trucks (or even transfer stations) were not used in 1985-1985"(page 15). We believe this to be erroneous since transfer trucks from Santa Monica arrived daily at the landfill during the eighties. It is incumbent for BFI to consistently use figures that reflect fact. BFI records the weight of every vehicle entering the landfill on a daily basis. Please require them to make at least the last few months of these records a part of this record so that the weight-to-volume ratios can be verified. 1464 1465 1466 1467

The traffic Impact Report in Volume II at"i" states ; "The proposed City Landfill would have a net airspace volume of approximately 31 tons..." This figure does not agree with the proposal. Why? 1468

The landfill has now been operating for over one year, although this has been at a smaller than permitted volume. Has there been any increase in traffic accidents in the vicinity of the analyzed intersections in that period and did any involve garbage trucks? 1469

Will all trucks, not servicing the neighborhood, that are over the current weight restriction be precluded from using Balboa Blvd? 1470

Appendix Liner Section

This section describes several different liners. Which one will be used on the new site? Will uniform construction be used throughout on side slopes, as well as underneath the waste pile. How will the chosen liner accommodate the differential subsidence, if the liner is placed on existing trash? During the '94 earthquake did any other landfill in the affected area have a liner placed over waste? If so, how did it perform? 1471 1472 1473 1474

Please explain diagrams #6,#7 and #8. It appears that the liner will be placed on intermediate cover. Since the landfill is closed, won't the final cover be in place? If not, why not? What is the permeability of the buffer soil? What is the sub-base made of? Will this be used on all side slopes? 1475 1476

In #8 you show a vegetation layer of 1 foot. Your revegetation plan prepared by Mr. Osterling calls for 15 feet of final cover. Which is accurate? Will you be using the revegetation described in the program included in the Appendix and in the topical response in Vol.A of the Response to Comments? 1478 1479

Appendix C7

Why did you not give as much statistical analysis and consideration to the population of Sylmar as you did to Granada Hills-Knollwood in your analysis of minority and socio-economic impacts? The address of the dump is Sylmar and, according to your own data, identical in proximity to the dump. Will you combine these statistics to give a more realistic picture of the affected communities. It is inaccurate to use 2 miles as a distance for either of these communities; the trash will be much closer than the entrance. Your maps show ancillary facilities within 600 yards of homes. The demographics have changed dramatically since the last census in 1990. The declining home prices have caused many changes. Will you do a more recent study to provide an accurate basis for your conclusions? 1480 1481 1482 1483 1484 1485

Because of problems with dust violations, the AQMD required BFI to install an anemometer to record wind speed on the old landfill. Will you please include these site-specific records from the last years of the City operation and those from the current operation. The anemometer readings in the appendix are not usable because no location is indicated. The readings from the city berm must be included. 1486 1487 1488

Biota Appendix B2 section 5 page 5-1

Mitigation measures are recommended for each of the following where "significant impacts are identified": Arroyo willow series, southern willow scrub, coast live oak woodland, Venturan coastal sage scrub, slender mariposa lily and the San Diego horned lizard. With the exception of the coast live oak, we cannot find the mitigation proposals for the other communities. Where can we find them? 1489

Will the suggested mitigations for the mariposa lily be carried out as recommended by the consultant on page 5-2? It is said that impacts on this species will remain significant if transplantation fails. What measures are being used to insure that failure does not occur? 1490 1491

Appendix A6

The Conservancy biologist seems to believe that pumping ground water, needed for landfill operations, will pose a strong possibility of altering important ecological resources related to existing soil and substrate moisture regimes. The Conservancy states that "if a lack of significant adverse impacts cannot be conclusively demonstrated then the ultimate burden of such proof should be considered as a project requirement prior to any subsequent level of government approval." Where in this document is this issue discussed, and what proof is offered? 1492

Litter

The problem of litter is still with us, even after the dump has been closed since 1991. After the heavy rains of the last two winters, hikers in O'Melveny Park have observed a great deal plastic debris washed down from the dump into the side canyons. Again hikers in the far reaches of the canyons report wind blown trash from the current opperation in the County. 1493

The upper reaches of the steep cliffs and dense sections of underbrush in this wilderness park have been virtually impossible to clean, once fouled by litter. Fortunately, most of the paper has degraded over time, but the plastic, washed down into the canyons, remains a problem. In 1987, an inspection by the Dept of Sanitation showed: 1494

> "On several occasions the ridges and hillsides, contiguous to the landfill in O'Melveny Park, have been searched for windblown litter, in an effort to determine the extent of this problem. Although litter crews of 3 or 4 people have been observed successfully policing the park entrance, the grassy picnic areas, and the immediate trail and stream areas, there is a great deal of windblown paper and plastic bags, littering the hillsides and ridges. It has been determined that the sole source of this litter is Sunshine Canyon Landfill." 1495

For years, the community was forced to pluck plastic bags out of their trees and pick up papers from remote areas of the County. The wind blown trash contained income tax returns and business records from a firm in Santa Monica; we knew how much a man in Beverly hills paid for his dental crowns; we gathered up medical records and read about the very private medical problems of unsuspecting strangers. Trash burst out of the dump and went high in the sky, plastic bags and long streams of computer paper were carried aloft. 1496

Of rubbish blowing from the dump, the City Zoning Administrator, John Parker, said: "This is a definite problem involving a VIOLATION of condition 13" 1497

The community fears the return of this nuisance. 1498

Dust

This was, and will be, a problem with ominous health implications. Fugitive dust pollution, according to the A.Q.M.D., is responsible for 60,000 deaths nationally and 1,600 in the southland. When the dump was operating full tilt, and in the southern canyon, we breathed the dust - we ate the dust. Fire Department records will show you how many times they responded to calls in the area, only to find out that there was no fire, All of the intense smoke reported was not a forest fire, only dust from the dump! We have had guests take their children home, from fear for their health. We watched sadly, as old friends and neighbors moved to escape. We listened to our children cough and wheeze. How can you *possibly* consider inflicting this community with these problems again? 1499 1500

The proponent continues to ignore the fact that the existing landfill and the expansion are in a wind tunnel and that as the landfill rises the "sheltered" places will no longer exist. 1501

Violations

The Zoning Administrator put conditions on the dump, as did the AQMD. BFI protested at every juncture. At first BFI refused to accept AQMD's mitigations. On July 7,1988 the AQMD District Council testified: 1502

> "As I said earlier the District attempted to negotiate some additional variance conditions which would help to alleviate any future dust problems. In light of the fact that the petitioner" (BFI) "has told us at our prior meeting this morning that, I believe, they intend to not adopt any variance conditions dealing with dust. We have no choice but to oppose the granting of this variance...." 1503

BFI, rather than loose their variance, capitulated and reluctantly adopted AQMD's conditions. This was an action forced upon them and only reluctantly accepted.

Excerpts from the AQMD hearings show how duplicitous BFI was, in representing their project before the AQMD Hearing Board. As John Parker said, 1504

> "THE ADMINISTRATOR CONCLUDES THAT THERE WERE VIOLATIONS OF THE EXTANT GRANT, PROBABLY INADVERTENT INITIALLY, BUT EXACERBATED BY LACK OF CANDOR AND AGGRESSIVE ATTEMPTS TO CURE ON THE PART OF THE OPERATOR."

The AQMD did not cite the dump, when they concluded that they were "doing what was required and the winds were over 25 miles an hour."

The Enforcement Manager of the Air Toxics Control Branch of the AQMD testified as follows at the AQMD Hearing on July 7,1988:

> "Since the beginning of the year through the end of June we have investigated 83 dust complaints from the surrounding neighborhood and in many of those cases District inspectors were able to confirm that there was dust in the neighborhood and that they could see that it was from the landfill property. However we did not issue a 403 violation because it was our feeling, it was District Staff feeling, that the landfill was taking every precaution to prevent fugitive dust emissions. Those were very high wind conditions.....And so no notices of Violation resulted although there was a dust problem from the landfill in the residential neighborhood."

1505

As a result of this hearing, the AQMD attached more conditions in the hope of lessening the problem. There was now at least a greater effort made to control dust although the problems continued.

1506

We believe that this law, that protected the dump from receiving citations, explains why there were so few issued, in view of the enormous problem.

1507

As you can see, strong winds are not an aberration, but normal in the area. How can we believe that these same conditions, that did not protect us before, will protect us in the future? When the Zoning Administrator said that the landfill was in the wrong place, it was to these conditions, for which there are no mitigations, that he referred.

1508

1509

Appendix C 5-2

Odors

Here again, this document would lead you to believe that the community was imagining odors. Since, according to the AQMD inspectors, the human nose is the most sensitive instrument for detecting odor, we were at last not put at a disadvantage, by someone claiming to have more sophisticated instrumentation! There was a long period of time in the eighties, when BFI was taking lots of garbage, that the dump emitted really foul odors. Things got better when the new incinerator was installed. We have always challenged the statement that the odors came from the gas fields, or seeps in O'Melveny Park, as this document states. We believe they came from the dump. If the odors come from the oil well and gas injection storage areas that BFI owns and leases isn't BFI still responsible for the nuisance created? We are worried that if the dump expands, we will face a return of odor in the form of outgassing, since not all gas can be collected. This gas contains several cancer causing hydrocarbons and teratogens.

1510

1511

1512

Appendix C 5-4

Aesthetics

Although the area of the berm above the oil production area has been landscaped, the slopes of the City landfill remain an eyesore, even though it's been over six years since the landfill closed its gates. The existing slopes have insufficient cover and have not been properly closed as required by law. The City and the AQMD tried to get BFI to revegetate on numerous occasions. After 33 years in operation this is how successful the revegetation plan has been (show photo) From the I-5 the 210 freeway and the residential community of Sylmar the dump is an ugly blot on the landscape. Even the new County portion is without the intermediate cover required in the CUP. What extra measures, soil amendments, consultants etc. will be used to insure success? Will BFI post a bond in an amount sufficient to hire another company to revegetate, if they continue to be unsuccessful in their attempts to revegetate? Page C 5-5 Of the 1,367 coast live oaks planted in the buffer zone, how many have survived? I believe this to be an inaccurate number, since most of the trees in the buffer appear to be eucalyptus.

1513

1516

1517

1518

1519

CONDITIONS

For dates of conditions, see "The Dump's Zoning History"

1520 BFI operated acres and acres beyond its boundaries and, in the process, destroyed a wetland and scores of protected 1521 oaks *without a permit*. They illegally destroyed that 1522 portion of SEA 20 that extended into the City. When applying for the expansion they placed a misleading map in the EIR, on which the City SEA had been completely erased. The original map from the 1966 variance shows the destroyed wetlands *clearly beyond the variance line*. The only confusion that ever existed sprang from BFI's refusal 1523 to conduct a proper survey, in an attempt to cover their misdeeds. Instead of admitting, simply, that they goofed, the landfill boundaries started to *mysteriously* expand.

The City surveyors drew a map that showed the landfill to 1524 be *out of compliance*. The NVC always accepted the City's work, but a complete survey was needed because the city survey had only involved three fourths of the dump. BFI was ordered by the Zoning Appeals Board to pay for a 1525 survey, done by a surveyor that was mutually acceptable to BFI and the Councilman's office. BFI appealed this condition, claiming that it was "too expensive". They have *violated* yet another condition of the Variance by putting off doing this survey.

By exceeding their elevations, *another violation* for which 1526 BFI was convicted, BFI exacerbated the dust conditions and created an unnatural appearing ridge line.

BFI *violated* their permit by ignoring a condition that 1527 prohibited them from coming within 50 feet of the ridge-line.

BFI *violated* a condition of their permit, by not restoring 1528 the wetlands, in cooperation with the Dept of Fish & Game, as ordered.

BFI *violated* a condition of their permit, by not replacing 1529 the oaks removed in the north canyon, two to one, as ordered.

BFI has now refused to comply with City Zoning conditions 1530 that were ordered to correct past violations. BFI claims that the City no longer has jurisdiction. This was the 1531 issue at the last City hearing. Is it any wonder that the Chairman of the Zoning Appeals Board said of BFI at that hearing; "The disingenuousness on the part of the proprietary sector has made fools of us and made the people distrustful of the process."

BFI's violations of their permit were appealed and sustained through all levels of zoning review and finally 1532 to the full City Council. These are *proven violations* and their record must be considered before assuming that they will comply with conditions of any permit the City is considering.

It is appalling that the City is even being approached for 1533 this expansion considering the proponent's dismal past record. The community is afraid that it will soon again 1534 have to go through hearings when BFI has again violated their permit.

In 1989 the Zoning Administrator found:

> "Pursuant to section 12.27-B,5 of the Municipal code, the Administrator finds that certain conditions of the variance have not been 1535 complied with, and pursuant to Condition 13 of extant Case No.17804, that certain activities on the property have proven to be materially detrimental to the occupants of surrounding property"

The hours of testimony from the community, plus the photos 1536 of blowing dust and trash convinced the Zoning Administrator, and those at various levels of appeal, that the landfill was causing conditions that were detrimental to the community. The Administrator found permit violations 1537 in boundaries, elevations, ridgelines, and degradation of the water course. Similar conditions will exist in any 1538 future permit. Why will BFI now comply when they have cavalierly ignored their permit conditions in the past?

The City joined the lawsuit against BFI's expansion into 1539 the County. Why would the City now consider allowing BFI to return?

QUESTIONS ON THE EIR SECTION ON ANIMAL LIFE

p.4-139

1.The reference is to "numerous biological assessments and reports". How many does "numerous" exactly refer to? 1540

2. Did the consulting firms ask for any support information from environmentally-conscious groups such as The Sierra Club, groups that have an active interest in protecting the current ecosystem? 1541

3. Regarding data from the previous FEIR that has been "previously addressed", how do we know that those previous determinations are still relevant and not out-of-date? Ecosystems are constantly changing. 1542

4. As ecosytems are constantly changing, why does the EIR use information from 1989, over eight years ago? These assessments and reports should be made in 1997 so they are totally current- this area has changed considerably over the last eight years with, among other things, large urban development and a major earthquake. 1543

5. Who approved the biological consultants that were used in this report? Was it BFI? If so, then their reports are invalid as they represent an interested party. Who paid their fees? 1544

p.4-140

1. As ecosystems change, what is the relevance of reports from 1978 and 1985-86? Surely these are out-of-date? 1545

2. Shouldn't any relevant studies be performed today before a proper determination can be made of environmental impact on the animal life? 1546

p.4-141

1.How can a field reconnaissance survey be valid that did no examination between October and June, totally avoiding the impact of Winter on the area? This is in reference to the study by P&D Services . 1547

p.4-149

1.On p.2-84, there is reference to prevention of ponding of surface water to prevent insect breeding and the attracting of vectors.On p.4-149, there is reference to freshwater marsh habitats occuring onsite and , as the EIR says, 1548

> "Amphibians require moisture for at least aportion of their life cycle, requiring standing or flowing or flowing water for reproduction."

So if ponds are prevented, won't this result in the destruction of amphibian pond life? Won't this upset the natural ecological balance in this area?

2. If ponds are allowed to develop, doesn't this raise the likelihood of insect proliferation and , therefore, the transmission of waste out of the dump area? 1549

3. If "terrestial amphibians avoid dessication by burrowing underground", what is to prevent them eating/burrowing into the waste and then carrying waste residue out of the dump area? Surely they will also effect the removal of waste from the dump area in their faeces? Surely this spreads the impact of the dump far beyond its established limits? Is there any realistic way to prevent this while still maintaining the balance of the ecosystem? 1550

p.4-150

1. What is to prevent birds carrying off waste , including dead carcasses and rotting food, and depositing it over the protected recreational area of O'Melveny park where children play or over the housing areas? I often find dead mice in my pool, dropped by passing birds. 1551

2.What is to prevent birds carrying waste over a wide area in their excrement? 1552

3.The EIR says "The existing inactive landfill" contains "minimal habitat suitable for supporting a diverse number of bird species." What does "minimal" mean and who made this determination? Was it someone paid by BFI? "Minimal" still allows that there will be some impact, so what is this impact exactly? 1553

p.4-151

1. The EIR states that several raptor species have been observed foraging onsite. What will be done to prevent this? 1554

2. Why is there no reference to the prescence of coyotes and mountain lions in this area? Won't they be attracted to the waste area, bringing them closer to the housing areas? Won't they carry waste beyond the dump limits? 1555

3. Has there been a current 1997 survey to determine whether any of the wildlife are protected or endangered species? I see no evidence of this, but surely this should take place and that the EIR should not rely on old, possibly out-of-date studies? 1556

p.4-153

1.The EIR accepts that site conditions are attractive to the California Condor, an endangered species. The EIR then says that the likelihood of its prescence here is low. But surely "low" accepts that there is a possibility? What does "low" exactly mean? Who made this determination? 1557

2. Regarding the condor, the EIR states that the Condor has never been observed onsite by consulting biologists. But how long were their studies? Have they made a study recently ? I see no evidence of this and we must remember there are only 13 individuals in the current condor population. 1558

3. The EIR admits that the decline in the population of the Coastal california Gnatcatcher is attributed to the loss of coastal sage scrub habitat through development. The gnatcatcher is federally listed as threatened. Surely the dump would constitute such "development" that would threaten this species? 1559

4. The last survey on the gnatcatcher was 1995. Surely one should be done for 1997? 1560

5. Regarding table 4.4-4, the analysis of local wildlife, why is there no mention of coyotes or mountain lions , both which are frequently observed in these areas? 1561

p.4-165

1. A Golden Eagle, protected by the Federal Bald Eagle Act, was observed onsite during a previous study. Why was no extra effort made to determine whether it was nesting in this area? Surely a 1997 survey should be made to determine whether it has nested in this area? 1562

2. Thes same questions apply with respect to the White -Tailed Kite, another fully protected species? 1563

3. Why is the EIR quoting information obtained during a telephone conversation? Surely this should have been documented and validated? (re. Rick Farris conversation) 1564

p.4-146

1. If the mountain lion is a "passage Species" and "there is no evidence that wildlife use Sunshine Canyon for local or regional movement" into local mountains, then why do we frequently see lions and coyotes in this area ? Surely this information is wrong? 1565

p.4-172

1.The EIR admits that there will be a loss of animal life within the project site, upsetting the balance of the ecosystem. Will this not have a resulting effect on the ecosystem on a much larger scale causing permanent damage to the wild life population? 1566

2. By displacing the more mobile wildlife species, will animals such as coyotes and mountain lions not be forced down into housing areas? 1567

3. The EIR admits that there will be adverse indirect effects on wildlife such as the threat from increased vehicular traffic and the introduction of noise, litter, dust and other human debris into the habitat areas. Who has determined that these impacts are not significant? How did they come to this conclusion? When was this study made? What models were used in coming to this determination? 1568

p.4-174

1.What mitigation will be effected if raptor nests are removed?..These are protected under the CA Fish and Game Code. Is there a model for the success of any mitigation plans? 1569

2. When was the most recent study to see if California gnatcatchers occupy the site? 1570

3. Whose opinion is it that the impact on many species is considered "adverse, but not significant"? Is this based on a factual model or just a random opinion? 1571

p.4-178

1. It is stated that there will be no impact on any wildlife corridor, but does this take into account the attraction of food waste for predators in the area? There is no mention of this. 1572

It seems that we should make a strong effort to contact local ornithologists and Nature societies. If we 1573

could find evidence of nesting by the California Condor or the Coastal california gnatcatcher or the Golden Eagle, then it could be very, very helpful to us!!!!!!

Hope this is what you want!!

Julian Stone

Comments on Sunshine Canyon Landfill Draft SEIR

Dr. Stanley P. Sander
Senior Research Scientist in Atmospheric Chemistry
Jet Propulsion Laboratory*

Section 4.2.9 Health Risk Analysis. The entire health risk analysis as summarized in section 4.2.9 and detailed in appendix B6 is of very poor quality. It contains numerous unjustified assumptions, uses unscientific sampling methods and contains at least one serious arithmetic error which gives a value for the cancer risk which is too low by a factor of 10. This section should be completely revised using better emissions data, a much more sophisticated source-receptor model, and the results should be checked independently by SCAQMD staff. 1574

Given the poor quality of this section of the SEIR and the lack of independent detailed model verification by SCAQMD, the comment period for analysis of this section is believed to be too short. The comment period provided for future versions of the SEIR should be long enough to allow for detailed analysis of the work that has been performed by BFI. 1575

Detailed comments on this section are given below:

Comments refer to Appendix B6.

p. 2: The SCREEN2 model is not appropriate for the complex terrain in the Sunshine Canyon area. The assumption was made that the SCREEN2 results would provide a worst-case analysis which would provide an initial screening. There is no justification or reference to relevant literature upon which to base the conclusion that that SCREEN2 provides a worst-case estimate. 1576

In addition, the arithmetic error in the cancer risk calculation discussed below puts the overall cancer risk within a factor of 5 of significance which is well within the uncertainty of SCREEN2. A more sophisticated model must be used to model the complex terrain and micrometeorology encountered in the project area. 1577

The model calculations are based on flare emissions data from only one day, i.e. August 3, 1995. The use of only one day's sampling data on which to base the health risk analysis for the entire project is ludicrous and highly unscientific. It is well known that the emission rates of toxic contaminants in landfill gas is highly variable and depends on factors such as temperature, moisture, age of the fill, fill composition and a number of other factors. The sampling should have been based on a much larger number of samples (at least two per month) taken over a time period of a year or more to simulate the effect of varying soil moisture and temperature on the trace gas emission rate. The samples should be collected and analyzed by an independent testing laboratory which is not employed by BFI. These results need to be presented along with a credible statistical analysis which makes it clear what the worst-case emissions rates will be. 1578

In addition to variability in the composition of landfill gas, the test results are subject to additional uncertainties associated with sample handling and analysis procedures. There is no discussion in the SEIR of the details of the sampling procedures, i.e. type of flasks, preparation of the flasks, the chain of custody of the samples and the analytical techniques employed. 1579

*The comments expressed here are those of the author and do not reflect the opinions of the Jet Propulsion Laboratory, California Institute of Technology or NASA. This work was prepared by the author in his capacity as a resident of Granada Hills

p. 3: The meaning of the "less than" symbols for the benzyl chloride and chlorobenzene emission rates should be clarified. Does this mean that these TACs are below the detection limit? If so, the detection limits for all the TACs should be clearly stated so that the quality of the measurement techniques can be assessed. 1580

The health risk analysis does not take into consideration the emissions from the landfill which are not captured by the landfill gas system. It is well known that landfill gas recovery systems do not capture all of the landfill gas due to cracks and diffusion through the soil. These emissions are called "uncontrolled emissions" because they bypass the flare and are therefore released into the atmosphere untreated. Estimates of recovery efficiencies in the literature vary from 10-50%. If the flare combustion efficiency is 99%, then in the best case (assuming 50% recovery) then the emission rate of toxic air contaminants from the entire project will be a factor of fifty larger than the emissions rates from the flare exhaust, yet these emissions are completely ignored in the health risk analysis. Models such as BEEST-X contain area source algorithms that can estimate the increase in exposure due to these uncontrolled emissions. This is another reason why the SCREEN2 model is inappropriate for use in this project. 1581

Some of the values in Table 1 (TAC emission rates) are difficult to understand. It is assumed that the "less than" sign means that the emission rates are below the analytical detection limit. If so, why for example are the upper limits for the inlet and outlet rates for carbon tetrachloride different? If they are both below the detection limit, the values should be the same, i.e. the rate corresponding to the detection limit of the measurement. 1582

Also, how is it possible for the inlet rate for chloroform to be below the detection limit but the outlet rate to be measurable? 1583

Why are the combustion efficiencies for trichloroethylene and vinyl chloride so different from one another given that these compounds are chemically quite similar? 1584

These obvious questions detract from the credibility of the values presented in Table 1 and provide additional justification for a far more extensive sampling data base than the single set of samples provided here. 1585

p. 6: In order to estimate exposures the analysis uses a plume model called the "hybrid configuration". No justification is given for the derivation of this "hybrid configuration". It appears to be an arbitrary hand-drawn curve which lies between the "flat terrain" and "zero plume rise" models shown in Figure 1. Since the hybrid configuration curve is arbitrary, the point labelled "maximum" corresponding to the "worst-case" concentration is also arbitrary and could a factor of 10 or more larger. 1586

The use of what amounts to a completely downwind concentration profile curve shows clearly that the model employed in this analysis is far too simplistic and calls for a much more sophisticated analysis which takes into account the actual terrain and wind conditions. 1587

Table 3: There is a serious arithmetic mistake in Table 3. The formula used to calculate the downwind concentrations given in Table 3 is: 1588

Concentration ($\mu g/m^3$)=EMFAC($\mu g/s$)*(normalized plume concentration)/(normalization factor)

where EMFAC = emission rate of toxic compound from the flare stack
normalized plume concentration = .02138 $\mu g/m^3$
normalization factor = 0.001 g/s = 1000 $\mu g/s$

For benzene, for example the value derived using this formula is 1.13×10^{-4} $\mu g/m^3$ but the value in Table 3 is given as 113.4×10^{-6} $\mu g/m^3$ which is a factor of 10 smaller than the correct value. This mistake is made for every entry in Table 3. The correct value for the risk total is 1.82×10^{-7} which is a factor of 10 larger than the value in the table. While this is still below the significance level of 1×10^{-6}, it is lies sufficiently close to the significance level to trigger a much more detailed analysis. For the contractor to make an arithmetic mistake of this magnitude shows that this work has not been reviewed carefully by the contractor or the SCAQMD. 1589

General questions regarding the Proposed Sunshine Canyon Landfill. Please respond with specificity to the following concerns: 1590

1. How will the air pollution created by the proposed Landfill impact the health of local residents?

2. Why have no epidemiological studies been done in this area? 1591

3. What will the impact of air and noise pollution have on property values in the area? How will local home owners be compensated? 1592

4. What effect will the airborne contaminates caused by the project have on the LA Water Treatment Plant off Balboa? What is the methodology used to determine impact and all supporting data? 1593

5. Why is the EIR accepted as an objective document when the preparers were hired and obviously influenced by BFI and its commercial interests? 1594

6. Why is a Landfill that will have significant negative impact on the health and well being of local residents and school children even being considered? 1595

7. Exactly who stands to profit by this landfill at the expense of Granada Hills and Sylmar residents? 1596

8. Why isn't the waste being trucked to a non-populated area far from homes and schools? 1597

Specific Comments on EIR Noise Section

1. According to Noise Ordinance No. 144,331 of the City of Los Angeles General Plan Noise Element, (as sited on page 4-206), all residential zone noise should remain within the following parameters: 50 decibels during the day (7 AM to 10 PM) and 40 decibels during the night (10 PM to 7 AM). 1598

   If the zoning for the Sunshine Canyon Landfill area is changed to heavy industrial, (as is proposed), 75 decibels will be allowed, twenty-four hours a day. Please respond to the above comment.

2. My observations are not in agreement with the statement on page 4-207, 3rd paragraph from the bottom..that "the intervening north ridge line within Sunshine Canyon and the extended distance between the project site and these receptors serve as an effective buffer and shield these units from any potential noise impacts originating from landfill operations.

   - What is the source of this assumption? 1599
   - Where is the supporting data?
   - If the assumption cannot be supported, it should be revised and impacts reassessed.

3. Has BFI officially agreed to 1 - 5 in second paragraph from bottom on page 4-205? Who will enforce and monitor this? 1600

Comments On Traffic Section

Refer to section 4.13 transportation.circulation. Page 4-346, passenger car equivalents under Traffic Generation Criteria.

The EIR states that one transfer truck has approx the same impact on normal traffic operations as three passenger cars and one curb side collection trash truck is equivalent to two passenger cars.

- My observations are not in agreement with these assumptions
- Please substantiate assumptions with concrete data or remove from EIR 1601
- Provide supporting data that shows that the assumptions apply to each of the analyzed intersections
- Comment on the fact that the impact of a truck varies depending on road and traffic conditions. EXAMPLE: Multiple trucks at an intersection or section of road can create much greater impact than an equal number of trucks evenly spaced out in traffic.
- If the assumptions cannot be fully supported by data they should be revised and the impact should be recalculated

Refer to page 4-372, table 4.13-9 (Project mitigation measures). The second paragraph. 1602

The EIR states that no specific mitigation is assured regarding the San Fernando Road at Balboa intersection. Mitigation is a required part of a project proposal, so why is this omission being overlooked or accepted?

- If there is no guarantee that the mitigation will be provided, this section should be removed. 1603

Refer to section 4.13.1 Traffic top of page 4-334

Traffic studies can't be more than two years old. This a 2 ½ year old study. Also, at the time of the May 22, 1995 study, San Fernando Road was blocked.. Normal traffic had not resumed due to earth quake damage. 1604

- Please respond to the above objection.

General Comments Regarding Traffic:

BFI is now applying for an inflow of 14,250 tpd, resulting in 4531 truck trip ends. Even if this amount is reduced by the 937 average trips at the former dump, we are left with 3594 trip ends, clearly over the Districts level of significance. This figure does not even 1605

include the employee vehicles or the additional trucks that would be used to haul away recycled material. Furthermore the SWFP allows inflow to reach 17,500 tpd without further District review. These actions point to incremental approvals, in violation of C.E.Q.A

Please respond to the above comment

Please state exactly how many transfer trucks will be used per day. (Not <u>are</u> being used, but WILL be used, if the proposed landfill is in full operation) 1606

Hadar Plafkin, City Planner
Environmental Review Section
Office of Zoning Administrator
Department of City Planning
221 North Figueroa Street, Suite 1500
Los Angeles, California 90012-2601

RE: SUNSHINE CANYON LANDFILL EXPANSION
DRAFT SUBSEQUENT ENVIRONMENTAL IMPACT REPORT
STATE CLEARINGHOUSE NO. 92041053
CITY OF LOS ANGELES SEIR NO. 91-0377-ZC/GPA

Dear Mr. Plafkin:

Landfill Alternatives Save Environmental Resources (LASER), which I represent, is an environmental organization based in Newhall but active throughout Los Angeles County. Together with other community groups, LASER has coordinated its review of the Draft Subsequent Environmental Report for the proposed expansion of Sunshine Canyon Landfill back into the City with the office staff of 12th District Councilmember Hal Bernson. LASER is especially indebted to Greig Smith, Chief Deputy for the Councilmember, and to David Oeffling, intern with the Council office, for their help, patience and research.

Because other community members and the 12th District Council office are also commenting on various aspects of the DSEIR, this response focuses on the proposed expansion and its impacts upon the solid waste management policies of the City of Los Angeles. Under separate cover, LASER is also commenting further on landfill alternatives and water quality. Therefore, LASER wishes to incorporate all community statements and those of the Council office into its response. In addition, these comments will include aspects of the landfill expansion which particularly impact the Granada Hills community or adjacent land uses.

I. PROJECT DESCRIPTION

A. CURRENT OPERATION WITHIN LOS ANGELES COUNTY, VIA CITY ACCESS

Sunshine Canyon Landfill is a Class III landfill accepting non-hazardous solid waste which is wholly owned and operated by Browning-Ferris Industries of California, Inc., 14747 San Fernando Road, Sylmar, California 91342. It straddles the Los Angeles City-County line, but its current operations are wholly within the County and have a permitted capacity of 16.9 million tons. Its Operating Permit was issued by the County Department of Health Services Solid Waste Management Program on November 17, 1994 and expires November 17, 1999. Its wasteshed is Countywide, but out-of-County waste has previously been taken. 1607

An amended Conditional Use and Oak Tree Permit approved by the County Board of Supervisors on November 30, 1993 will terminate whenever the County fill design level of 1885 feet mean sea level has been reached. Daily and weekly tonnage limits, however, vary according to the following complex schedule: 1608

1. A 6,600 daily net tonnage limit and a weekly net tonnage limit of 36,000 tons are in effect until the County Board of Supervisors approves a revised CUP.
2. This revised CUP is to allow 8,800 daily net tons and a weekly net tonnage limit of 48,000 tons. 1609
3. A "cap" of 9,000 tons per day of solid waste (defined as exempt waste, or asphalt, concrete, soil, rock, wood chips and green wastes, which are not to be disposed of at the working face of the landfill, but are to be otherwise used at the site or transported off for reuse; plus refuse to be landfilled) to be referred to as the Gross Tonnage Limit until such time as the City of Los Angeles has certified that various traffic improvements have been made on San Fernando Road, such as widening and/or restriping and installation of traffic signals at the landfill entrance; restriping turn lanes at the intersection of Balboa Boulevard; and installing various traffic control signs and markers. 1610
4. After the above traffic improvements have been made, the daily Gross Tonnage Limit would be allowed to reach a maximum of 17,500 tons of solid waste. 1611

With such a complex schedule for implementing daily tonnages, the question must be asked about what the present daily/weekly limit is. Further, if the improvements listed in Item 3 above are made as part of the City CUP, does that automatically allow the operator to apply to the County for permission to take in 17,500 tons per day of solid waste? 1612 1613

B. PROPOSED CITY/COUNTY EXPANSION (THE PROJECT)

A previously operating landfill within the City portion stopped accepting waste when its Operating Permit expired in September, 1991. Negotiations with the Local Enforcement Agency over a Final Cover began before then, however, and only now appear to be finalizing. This "Cover" will also serve as a partial liner for the proposed expansion within the City. 1614

BFI is proposing to come back into some 194 acres of its City land to construct a 5,000 ton per day landfill with a final elevation of 2,000 feet mean Sea Level. This is to connect with a 42-acre vacant parcel in the County which abuts the City/County line. Development of this parcel would allow another 6,000 tons per day in the County, for a total of 11,999 tons per day. 1615

The County's Conditional Use and Oak Tree Permit has predicated the use of the 42-acre parcel, in Condition 10 b. on the requirement that the City allow 1616

further development of its land. This was done in order to allow a set-aside of vacant land in the western portion of the County land for preservation of trees. If the City does not allow development to at least 20 million tons capacity, then, according to Condition 10 d., the City is to be excluded from utilizing any portion of the landfill within the County. This exclusion is to be in effect until such time as the City approves a permit. 1617

The proposed enlarged landfill would allow a daily intake of about 11,000 tons per day of waste, for a total capacity of 90 million tons. The combined landfill configuration would occupy about 451 acres in both the City and County. 1618

While BFI must receive separate approvals from the City and County, it is also seeking permission to combine landfill operations, using one working face, about 18 to 24 months after obtaining permits from the City. 1619

BFI estimates that the landfill should be operational for about 26 years, and that total grading would involve about 10,044,500 cubic yards of earth material, all of which would be utilized on site. At first, earth for daily cover would be stockpiled within the northern portion of the existing landfill, but would later be relocated as necessary. The existing access road is to be relocated to the north and east of the present winding road. Generally, it would run along the rim of the proposed eastern landfill border and stop just before entering County land. 1620

The closed portion of the existing landfill would be used to house a wood and green waste recycling facility, a public drop-off area, a tree nursery and a gas flare station. Currently, a 100,000-gallon water tank and a flare station serving the old landfill are located to its immediate south. Two additional water tanks, each with a capacity of 265,000 gallons, are proposed, for a total capacity of 630,000 gallons of on-site storage. An educational center is proposed near the present landfill entry area. 1621

Generally, the southern portion of the applicant's land within the City is bordered by O'Melveny Park and a residential area of Granada Hills. There is a 100-acre "buffer zone," in the southeastern portion of the property adjacent to some of the residences; it has a restrictive covenant limiting the use of the land to non-industrial uses, with the exception of oil drilling. A portion of the Cascades Oil Field is located there and is leased out by the applicant. 1622

II. SIMULTANEOUS PROCESSING OF EIR CERTIFICATION AND ZONE CHANGE REQUEST

Along with certification of the Subsequent Environmental Impact Report, the applicant is seeking a General Plan amendment from the current "Agricultural" land use shown in the Granada Hills-Knollwood Community Plan to a "Heavy Industrial" use. This would result in a Zone Change from A1-1-0 to M3-1-0. All previous approvals within the City were for a variance for a nonconforming use within the A1 Zone. 1623

The Planning Commission is empowered to certify environmental documentation and approve or disapprove zone change requests and General Plan Amendments simultaneously. However, the zone change request and General Plan Amendment are to be tracked separately from the SEIR; at one point they even were on a different timetable. However, the Department acceded to a request by the Council office to have both the zoning and environmental document comments due on December 5, for which LASER is appreciative. 1624

Unfortunately, the general public does not understand the nature of this "bifurcated" process, even though the recent "key group" community meeting held by the applicant supposedly attempted to explain it. Because the printed material and the presentations largely dealt with environmental issues, confusion still abounds. 1625

Therefore, LASER requests that whenever zoning matters appear in community comments to the Draft Subsequent EIR, the response from the developer's consultant, Ultrasystems Environmental, Inc., state that because the matter addresses the proposed Zone Change request, the concern is being forwarded to the Hearing Examiners to be considered in their recommendations to the Commission. In addition, the City is reminded that Section 15204 (e) of the California Environmental Quality Act states that:

> "This section shall not be used to restrict the ability of reviewers to comment on broader isssues and on the general adequacy of a document or to reject comments not focused as recommended [by CEQA]..." 1626

For the future, the dual-track process needs to be clarified and response times synchronized at the time environmental documents are distributed. The letter stating the time comments must be received by the Planning Department should state the section of the Department to which all zoning issues are to be sent.

III. COMMENTS ON THE DSEIR SHOULD BE REPRODUCED IN THEIR ENTIRETY

CEQA, Section 15132, does allow discretion in how comments and recommendations received on the draft document are to be handled, by stating they can appear in the Final EIR "either verbatim or in summary." However, it is possible when summarizing comments in order to respond to them to lose the meaning of an individual comment. Therefore, LASER requests that all comments be reproduced by Xerox in their entirety and that the consultant indicate responses by numbers which appear immediately following each letter. 1627

IV. BACKGROUND OF THE PRESENT PROPOSAL

Landfills at this time are necessarily an important part of any solid waste management program. Nonetheless, it should be remembered that they have severe, inherent environmental problems which at best can only be mitigated in part. 1628

The greatest environmental danger from landfills comes from the amount of air pollution they produce. Recent studies by the National Aeronautics and Space Administration identified the composition of "greenhouse gas" in part to be 55 percent carbon dioxide and 15 percent methane. Methane usually comprises more than half the components of landfill gas and carbon dioxide almost as much. It is not surprising, therefore, that landfills rank sixth in the creation of greenhouse gases (*MSW Management*, December, 1994). 1629

A. FULL EXTENT OF SUNSHINE CANYON LANDFILL PROPOSAL

The proposal for Sunshine Canyon Landfill expansion, for 5,000 tons per day in the City portion, cannot be separated from what the County is allowing and in fact encouraging by its 1993 Conditional Use Permit and the Solid Waste Facilities Permit of 1995. The County portion of the landfill has a maximum 1,885 foot mean sea level elevation, but ultimately will allow 17,500 tons per day of rubbish and other material, including green waste, to enter. 1630

If the City grants in full the tonnage Browning-Ferris Industries is requesting, then Sunshine Canyon Landfill would be permitted to accept 22,500 tons per day. 1631

Further, because the proposed City expansion proposes to extend to a 2,000 foot mean sea level elevation, there is little doubt that the proponent would soon be requesting the County to allow a similar rise in elevation within its jurisdiction. 1632

Thus it should be realized that Sunshine Canyon Landfill would allow more daily tonnage than the projects now being planned for remote desert areas. These landfills would accept no more than 20,000 tons per day, although they each would have enough total capacity to last between 50 and 100 years. 1633

Make no mistake: Browning-Ferris Industries and Los Angeles County intend for Sunshine Canyon to be a large, regional landfill. And, lest we forget, all material to be dumped or used on site can only enter through a City access road, off San Fernando Road, which is also within the City limits. 1634

B. ARRANGEMENTS COVERED BY SETTLEMENT AGREEMENTS

The existing landfill area within the City was closed in 1991 when its permits expired. Browning-Ferris Industries next applied to the County for landfilling within the County; its plan was similar to what is now being proposed for the County-City landfill. Access was to be through the City. Litigation by both the City and a Granada Hills community group to prevent use of the City access followed. The City action resulted in two tri-party settlements. 1635

1. AGREEMENT I. Signed in 1994, the first agreement provided for Browning-Ferris Industries to compensate Los Angeles for the problems associated with having a landfill at its borders. BFI agreed to contribute a sum totalling $4,500,000 into the General Fund and into a Trust Fund for community improvements, starting 90 days after disposal operations began in the County. (These 1636

operations began in July, 1996.) Payments would be completed into the Trust Fund in 1999.

In addition, BFI agreed to pay $1,100,000 for a "City environmental program," which would also begin with the onset of County landfill operations. These monies would be paid into the City's Environmental Affairs Fund; for the first five years payments would be $55,000 per year, followed by a ten-year period of payments in the amount of $82,500 per year. The environmental fund would be for the creation and expansion of riparian and wetland habitat, and oak and other native plant restoration activities, as well as recycling activities and public information. 1637

In this regard, it should be noted that the County landfill, located in upper Sunshine Canyon, destroyed about 8,500 oak trees and many other varieties as well. For this reason, BFI also agreed to donate 500 oak trees for replanting by the City, provided that the City foot the cost for planting and in turn agreed to a careful monitoring program. 1638

In return, the City agreed "to expeditiously process BFI's application" for a Zone Variance for an access road through the applicant's land within the City to the County. BFI also agreed to careful [illegible]s on its landfill liner in the County, and to request the County to remove the restriction against the City using the County landfill. 1639

2. AGREEMENT II. Signed on December 8, 1995, this agreement provided for ministerial processing of permits for the access road after the Zoning Administrator granted the Zone Variance allowing a non-conforming use within the A1 Zone. BFI was also granted the consideration of "Parcel B for future alignment of the access roadway. 1640

BFI additionally agreed not to accept any out-of-County waste for 90 months (7 1/2 years) following the opening of the County portion of the landfill, provided that the City agreed to dispose "not less" than an average of 1,250 tons per day of municipal solid waste. This would allow the City to pay a special low rate of $16.00 per ton plus tax tipping fee during the same period, which could increase annually only as much as the Consumer Price Index, but not more than three percent per year. If the City wishes to dump more waste, in excess of 2,500 tons per day, it would pay the lowest tipping fee BFI charges to its larger contract clients. This is the price that will also prevail if the City wishes to continue using the landfill after 90 months. 1641

This Agreement also modified the payment schedule for BFI's contribution to the City's environmental fund. The present agreement is for an initial payment of $550,000 within three months of County landfill operations beginning, plus $27,500 per year for the first five years. For the next 10 years, the payments will be $41,250 per year. It should be noted that some of this funding and oak trees have recently been used for a restoration project within the Arroyo Seco. 1642

It should be noted that other than agreeing to consider the relocation of the present access road to County land, the City has no legal obligation to approve the present proposal for a 5,000 ton per day expansion of the BFI landfill within the City portion of the proponent's land. 1643

V. WHY THE NECESSITY FOR A 22,500 TON PER DAY LANDFILL ABOVE GRANADA HILLS

Condition 10 (b) of the County's Permit, stating that BFI cannot use the 42 acres of land between the existing landfill unless the City also allows landfilling once again on the BFI land within its jurisdiction, is supposed to have been imposed in order to save the trees within East Canyon, which would become a protected area. However, the County itself removed the status of its own Significant Ecological Area No. 20 from much of these lands in order to permit the existing landfill. 1644

Therefore, it may be concluded that other matters are fueling the desire to create a major regional landfill capable of receiving 22,500 tons of waste and "exempt" materials per day on land that is adjacent to O'Melveny Park in the City and close by single-family residences. 1645

A. LOS ANGELES COUNTY COUNTYWIDE SITING ELEMENT

The Draft Subsequent Environmental Impact Report does include information on the Los Angeles County *Countywide Siting Element*, taking information from the January, 1996 Preliminary Draft. This document, while presenting data on landfill capacities, states that it is County policy to have excess daily disposal capacity equivalent to the largest daily tonnage permitted within the County. To date, this is the Puente Hills Landfill, which is permitted through 2004 for a daily limit of 13,200 tons. No municipally collected refuse from the City is accepted at this landfill, although some may inadvertently come from transfer stations. The *Siting Element* shows that in 1995, an average of 10,341 tpd were being deposited at Puente Hills (Table 3-1). 1646

The County also defines a "garbage crisis" as existing when there is "...a comparison of the projected date of daily permitted disposal capacity shortfall with the date additional daily capacity can be permitted." (*Siting Element*, page 4-18.) By County definition, we will be in a "garbage crisis" by 1999 (Table 4-5). However, because a number of landfills have closed since the date of the draft document, it is safe to say that the County now considers itself in a garbage crisis. 1647

Within the City's sphere of landfills, Lopez Canyon Landfill, the last City owned and operated landfill, closed in July, 1996--just as the County portion of Sunshine Canyon Lnadfill was opening. Mission-Rustic-Sullivan Landfill and Towsley have been removed from consideration. Land for the Elsmere Canyon landfill is now also owned by BFI and its future as a landfill is in doubt. Only Chiquita Canyon Landfill in Newhall is open and has recently been permit- 1648

ted for twice its 1995 daily tonnage, going from about 5,000 tpd to 10,000 tpd. In the Northwest County area, only Sunshine and Chiquita are operational.

B. NORTHWESTERN COUNTY PROJECTED GROWTH: FATAL FLAW OF THE SDEIR

While the Draft SEIR does discuss the *Countywide Siting Element*, it remains totally silent on a critical issue: approved and proposed new development in Santa Clarita and the Newhall Ranch and Land Company. No figures for growth are mentioned, nor is the increase in the area's waste stream caused by this growth. Consequently, the traffic analysis contained in the SDEIR does not disclose this projected increase, much of it to be in place well before the end of the 26-year lifespan of the proposed City-County landfill in Sunshine Canyon. 1649 1650

David Oeffling, intern for Councilmember Hal Bernson, was requested to research this information. His information determined that about 40,000 additional dwelling units have been approved by the City of Santa Clarita within the past several years, some of them not far from Elsmere Canyon. The proposed development of the Newhall Ranch land is to include about 24,000 dwelling units. This means that between them the Chiquita and Sunshine Canyon Landfills, as the only two landfills in the Northwestern County area, will need to accomodate about 64,000 additional dwelling units plus the commercial development they will require. Industrial development is also occurring in this area. 1651 1652

In what may be described as the fatal flaw of the Subsequent Draft EIR, the failure to disclose or analyze the impacts of this additional development means that there are inadequacies in discussing many of the environmental impacts as they pertain to the expansion of the Sunshine Canyon Landfill. 1653

1. WASTE STREAM ANALYSIS REQUESTED. The proponent is requested to provide an analysis of the existing waste stream for the City of Santa Clarita. Within the unincorporated County area, the communities of Val Verde, Castaic Junction, Stevenson Ranch, Del Valle, and the Newhall Ranch need to be analyzed as well. All approved growth and proposed development needs to be listed and discussed in terms of its waste stream. 1654 1655

2. TRAFFIC ANALYSIS OF THE I-5 FREEWAY. The traffic study by Linscott, Law and Greenspan analyzes only intersections which, with one or two exceptions, includes only the City of Los Angeles. However, the Golden State Freeway contains most of the traffic from these areas southbound to and from the City. Its present Level of Service during peak periods and the impact from the projected development need to be analyzed and included in the SEIR. The California Department of Transportation (CalTrans) should be able to provide these figures. Also, the present and future traffic along The Old Road between the Stevenson Ranch and the Sierra Highway should be analyzed, because together these two roads are the only routes through the San Fernando Pass. Not until these figures are provided for future ambient conditions can there be a true analsyis of the landfill traffic. 1656 1657 1658 1659

3. EMERGENCY FIRE RESPONSE FROM COUNTY AREAS. The SEIR should take into account the projected growth from the North County area as it discusses the adequacy of fire and emergency medical response times from relief facilities in Santa Clarita. The SDEIR, pages 4-391 and 4-392 refer to Los Angeles County Fire Station No. 124 on Pico Canyon Road in Valencia, which is able to provide backup fire and paramedic relief. This is about 6 miles from Sunshine Canyon Landfill. According to the SDEIR, response time is about 4 to 5 minutes. 1660 1661

County Fire Station 73 on North San Fernando Road in Newhall, about 6.25 miles from the landfill, has a response time of about 11 minutes. Fire Station 76 on Henry Mayo Drive in Valencia has easy access to the divided expressway State Route 126, which is close to the I-5. In addition to fire fighting capability, it maintains a 5-person hazardous materials squad. It is about 11 miles from the landfill, and its present response time is about 10 minutes, according to the SDEIR, page 4-392. 1662 1663

However, a glance at *The Thomas Guide* for Los Angeles County, shows that in addition to serving Santa Clarita, all these stations are also needed for the nearby Six Flags Magic Mountain recreation facility. Are additional fire and paramedic stations needed to serve the expected growth in the area? Will they be able to continue serving the landfill with the same response times? 1664

It is clear from the above discussion that it is the projected growth for the immediate area of the County that is fueling the need for a large, regional landfill. The *Countywide Siting Element* contains a largely theoretical analysis of County-wide landfill capacities, as well as County-wide projections of the solid waste stream. The reality, however, is that most of the growth within the County is occurring in the Northwestern County area—precisely the area to be serviced by Chiquita and Sunshine Canyon Landfills. Failure to consider this aspect of future needs means the Draft SEIR is grossly inadequate. 1665

VI. BACKGROUND: STATUS OF CITY'S SOLID WASTE PROGRAMS

A. SOLID WASTE STREAM ANALYSIS

1. 1990 BASE YEAR FIGURES. According to the 1994 City of Los Angeles *Solid Waste Management Policy Plan*, in 1990, the City's total waste stream was officially estimated to have been about 4,782,761 tons. Known as the "Base Year Figure," this is the amount from which all else must be calculated for the purpose of the State's Integrated Waste Management Act of 1989, referred to as "AB 939." By 1995, about 25 percent of this figure was to have been diverted from landfills, and by the year 2000 fully 50 percent is to be diverted. Failure to achieve these diversion rates can result in fines by the California Integrated Waste Management Board of up to $10,000 per day. (To date, no fines 1666

have been levied by the State Board.) AB 939 is the State's basic recycling law, enacted by the Legislature in response to a perceived national and State shortage of landfill space.

It has since been recognized that the "landfill crisis" was one of cost rather than a true lack of space, especially in the East, where landfill tipping fees in excess of $100 per ton were thought to be conceivable. It is as well a crisis of "permitted" landfill space, because landfills are universally acknowledged to be a "Locally Undesireable Land Use" and thereby difficult to site. Here in Southern California, tipping fees now range from just over $20 per ton to more than $30. 1667

The Solid Waste Management Policy Plan breaks down the Base Year Figure further: Of the 4,782,761 tons comprising the total City-generated waste stream, about 3,798,662 tons of solid waste were disposed in permitted landfills, corresponding to approximately 12,000 tons per day. Of this amount, about 40.1 percent was collected by the Bureau of Sanitation, and comprised both the residential curbside collection from 720,000 single-family houses and small apartments under five units, as well as material from City departments. 1668

About 984,099 tons were diverted from landfills, discounting "inerts" such as asphalt, biosolids (sewage sludge), and scrap metals. This amounted to about 20.1 percent of the waste stream being diverted. The relatively small, privately collected industrial sector led the way in recycling; 59.3 percent of its waste stream was diverted. The privately-collected commercial sector recycled about 20.7 percent. About 130 haulers were involved in private collection. The City-collected waste recycled but 9.9 percent because the curbside recycling program was still in its pilot stage at this time, with but 19,000 tons being diverted. 1669

2. 1995 WASTE STREAM FIGURES. According to the Draft *Annual Update*, at present being approved by the City, the largest change in reporting diversion rates in 1995 was that the responsibility shifted from cities to counties. Counties are allowed to report data based on landfill disposal figures. 1670

The City of Los Angeles, however, elected to continue its previous calculations because it believed the knowledge gained from the results would allow its excellent tracking record of targeted materials and industries to remain focused and subject to rigorous monitoring. The County has objected to this, but as of this date the CIWMB is accepting the City's calculations. In actuality, the County's disposal figures differed by only 0.3 percent, according to the Draft *Annual Report*, page 1-5. 1671

The City's calculations showed that some 3,365,000 tons of the total 5,854,372 generated tons were disposed of at landfills in 1995, down about 11 percent from 1990 (page 1-4). Thus, even though the total generated waste stream was up by 18 percent from 1990, the City showed a reduction in diversion. 1672

The most prevalent materials disposed in landfills Citywide were food and paper goods of all kinds, especially kraft and "remainder" paper. Unlike 1990, yard trimmings were greatly diminished in quantity, because these were an early "targeted" material by the City's Integrated Solid Waste Management Office. 1673

Private haulers, in 1995 numbering close to 150, disposed of 54 percent of the City's waste stream, about the same as in 1990. Their disposal quantities decreased from 2.08 million tons in 1990 to 1.81 million tons in 1995, a decrease of 13 percent, according to the *Annual Report*, page 1-5. Self-hauled waste to landfills was estimated by gate surveys at landfills to comprise about 10 percent of the total disposed tonnage (page 1-7). 1674

Various City agencies controlled only 39.5 percent of the total disposed waste, lower than the 44.6 percent tallied in 1990. The decrease is believed to be due to extensive recycling efforts. 1675

3. EFFORTS SINCE 1995. The City is making extensive efforts, as a result of the numbers found in the 1995 *Annual Report*, to target City government-generated waste and through ordinances to have various departments purchase recycled materials. Extremely little yard waste is delivered to landfills from the City's separate automated yard waste collection, except from contaminated containers or other special situations. This is because the City has adopted a policy of re-use for all such waste. In February of this year, the BOS reported that 98 percent of all yard trimmings were being recycled, mostly as part of an out-of-town composting program. The materials are first dropped off at wood chipping facilities and then transported to the facilities. Some is being done at a Valley composting facility. 1676 1677

Food waste composting programs are being instituted in the Downtown Produce Mart, according to the ISWMO. A two-year Citywide automated "blue bin" recycling program has recently begun in the West San Fernando Valley, replacing the complex "yellow bin" semi-automated program. It is hoped this single-stream recycling program will make it easier to recycle all clean paper and other materials, which under the old program had resulted in low rates of recycling of about 7 percent, according to the Bureau of Sanitation. Even the West Valley and the Westside, the two highest recycling areas of the City, had recycling rates of about 11 to 14 percent in 1996. 1678

Nonetheless, the City has concluded that it has achieved an AB 939 diversion rate of 44.5 percent in 1995. All earthquake debris has been excluded from this figure. However, the City's debris removal program recycling rates were so successful that the State has used it as a model for similar disaster planning. The City collected over 1 million tons of earthquake debris; it disposed of 330,890 tons and recycled 785,727 tons under special contracts. Unfortunately, according to the *Annual Report*, the construction industry did not continue its recycling practices when allowed to revert back to free market conditions. More effort is needed in this area. 1679

B. LANDFILL DISPOSAL STATUS

Since the publication of the *Countywide Siting Element* and the completion of calculations for the City's AB 939 waste generation figures for the *Annual Report* for 1995, conditions for disposal of Los Angeles's solid waste have changed dramatically. Lopez Canyon Landfill, the last City owned and operated landfill, closed in July, 1996 as the County portion of Sunshine Canyon Landfill was beginning its operations. 1680

While the amount of material being taken to landfills is generally less than it was a few years ago, the City now has contracts with two privately owned landfills: Bradley West, owned and operated by Waste Management, is under contract to the City through 2001. The City has contracted through 1999 with BFI to accept about 1,250 tons per day, as per the tri-party Agreements. According to the Bureau of Sanitation, about 1,000 tons per day are going to Sunshine. The West Valley and West Los Angeles west of the 405 Freeway are sending their trash to Calabasas Landfill, because it is within its stipulated wasteshed. The old BKK landfill closed in September, 1997, and waste going to this landfill, from about 3,500 to 4,250 tons per month, is now being divided between the other three. 1681

As of June, Sunshine was receiving about 24,657 tons per month direct haul. Some material from the BLT transfer station in Downtown Los Angeles was also transported to Sunshine, but most went to Bradley West. In June, that landfill received about 9,130 tons direct haul. BLT received 33,165 tons. Calabasas received about 2,400 tons to 3,700 tons per month direct haul. 1682

Through June, 1997, according to BOS reports, the City disposed a total of 437,911 tons at landfills. That roughly corresponds to an annual rate of 875,822 tons. It should be noted that at present, because of contractual arrangements, Bradley West is receiving most of the transfer trailers, while Sunshine is receiving most of the direct hauled material. 1683

C. PROGRAMS FOR THE FUTURE

In addition to the AB 939 goal of achieving a 50 percent reduction of the 1990 waste stream diversions, which the City in 1995 was well on the way towards achieving, the City's *Solid Waste Management Policy Plan* sets a further goal: a 70 percent reduction by the year 2020. To achieve this, in light of the fact that by that time the total amount of solid waste generated within the City will most likely be higher than it is now, will take considerable effort. The 18 percent rise in the total waste stream evidenced in 1995 is just an example which will keep repeating. 1684

Having available a close, inexpensive landfill will, of course deflect the City from this goal. The City's massive investment in its residential recycling program will be lost if too much capacity is made available. Yet, there is a 1685

place for landfilling in the City's future. Not all materials can be re-used, and the City's natural population increase and rise in business activity assures higher generation rates. Future programs must, therefore, focus on Citywide source reduction as well as landfill diversion. Until then, the Bureau of Sanitation is looking at three programs:

1. SHORT-TERM: THREE TO FIVE YEARS. Within the next six months, the Bureau will be sending out Requests for Proposals for an unlimited timeframe in order to develop a new landfill disposal program. The RFP will be sent to government entities and private waste haulers alike. Only landfills that are permitted and operating will be considered as final disposal sites. 1686

2. MEDIUM-TERM: FIVE YEARS . The Bureau is currently seeking to upgrade its District Yards at a cost of $19 million. More importantly, the BOS is seeking to purchase two sites, the existing BLT Transfer Station in Downtown Los Angeles, at a cost of $261 million, and a new site adjacent to Bradley West in the East Valley for $231 million. Both would become City-owned transfer stations and/or partial Materials Recovery Facilities. The savings over the present use of privately owned facilities is claimed to be $208 million. The plus side is that the City would then be able to exercise more control over disposal and recycling; the down side of this is that it is almost a one-half *billion* dollar program. 1687

3. LONG-TERM: FIVE YEAR PLUS. Two programs are planned. The first is to award an RFP for alternative disposal programs. As a result of the closure of Lopez Canyon Landfill in 1996, the City believes it needs to seek out innovative technologies to landfilling. However, the reality is setting in as it now seeks to award the RFP. The technologies are not fully tested for large-scale municipal solid waste, or they involve the use of yard trimmings, which are not now sent to landfills. Then too, their size is about 100 tpd, which would be equivalent to the amount now sent to a small landfill. 1688

4. LONG-TERM: Another RFP for landfill disposal, this time perhaps to include rail long-haul to desert areas of the State. The problems are the reliability of the railroad and the cost of transportation added to the tipping fee and possible County host fee. 1689

VII. THE SDEIR IN LIGHT OF THE CITY'S PLANS

Two areas of the SDEIR are of particular concern to LASER in light of the City's plans and the previous discussions of this response. The first is the traffic study and the second is the totally unrealistic discussion of alternatives. 1690

A. SDEIR TRAFFIC STUDY

1. Outdated Traffic Studies. Because this document has been held in abeyance, 1691

traffic projections for future construction within the City and for the impact the landfill expansion proposal would have on them appear to be outdated. 1995 is the year given for "Existing Conditions" and 1998 for Conditions at the time the project comes on line. The problem with this timeframe is that it is now almost 1998 and the project is nowhere near ready to come on line. Table 4.13.3 and 4.13.7 are specifically referenced. LASER requests that these tables be updated to 1998.

Considering that this is a landfill to be operational for 26 years, these are totally inadequate. A minimum spread of five years would be more in keeping with the landfill development. It takes a long time to move over 10 million cubic yards of earth, even if it is on site. At what date would the City portion plus the 42 acres in the County become operational if construction begins in 1999—a likely scenario, if over-optimistic. The date operation begins is the date that traffic projections should be considering, not a date that is upon us as the response period of the Draft document ends. 1692

2. Ambient Growth Rate. Linscott, Law and Greenspan reports in both volumes refer to a one percent ambient growth rate within the City for their projections. The full report in the Appendices mentions an additional equation in conjunction with the one percent rate. Yet, according to Allyn Rifkin of the Los Angeles Department of Transportation, the Department has for years used 2 percent as its ambient annual growth rate. 1693

Linscott, Law and Greenspan used this 2 percent rate for its traffic study of the proposed Constellation Place office tower in Century City (DEIR Appendix, page 49 of the traffic study.) This was in October, 1996. The traffic study for the Draft EIR for the Elsmere Solid Waste Management Facility, prepared in January, 1995 by Dames and Moore, states plainly that, using CalTrans calculations, a 3.7 ambient growth rate was used in its study (Volume I, page 13-8). 1694

In addition, the City is reminded that the County Department of Public Works is at the very least a Responsible Agency under CEQA. It must be forthcoming with the additional information requested earlier in this response on future growth and development within the Northwestern County area. 1695

B. PROJECT ALTERNATIVES

It is most unfortunate that the discussion of project alternatives, with the exception of the "No Project" and the "Reduced Volume" alternative—although this is problematic—has almost nothing to do with the reality of proposed City programs. The City is intending to issue an RFP not for a specific landfill, but most likely for a private hauler to take the trash to whatever existing landfill or landfills have space to accomodate the City. By overlying on the County's theoretical discussion of landfills in its *Siting Element*, an inaccurate picture is presented. It should be remembered that the City will be requiring the the landfill or landfills be fully permitted and operational. The hauler will bear the responsibility of determining which landfill to use. 1696

A check with Southern California landfills is a better way to determine what is presently available as an alternative. In the first place, no rail long haul landfill in California is fully permitted and operational at this time. The Mesquite landfill project, operated by U.S.A. Waste, is perhaps the closest to coming on line, but it will not qualify for discussion in any RFP the City sends out within the next few months. La Paz Landfill in Arizona is owned and operated by the applicant. It would only be an alternative if Sunshine Canyon is not available to the City. However, considering the legal issues binding the City to Sunshine, this is unlikely to occur for the foreseeable future. 1697

El Sobrante Landfill in Riverside County, owned and operated by U.S.A. Waste, has yet to receive permission to expand, although the County expects a decision by June, 1998. If this occurs, then U.S.A. Waste will determine the terms of disposal, which must include a host fee. Only U.S.A. vehicles will be allowed to enter the landfill with out-of-County trash. 1698

Chiquita Canyon Landfill has recently been allowed to expand from about 5,000 tpd to 10,000 tpd. It too is owned and operated by U.S.A. Waste at this time. This landfill has conveniently been "overlooked" in the discussion of alternatives; however, if U.S.A. Waste does respond to the City's RFP, this is the likely short-term landfill it will propose. 1699

Orange County has two landfills which also may be considered. Olinda is the closest, especially to the BLT transfer station. However, there is currently a problem with access through Brea, according to the County. It is served by various private haulers. The Frank M. Bowerman landfill in Bee Canyon near the El Toro Airbase is also available under the same terms. Tipping fees are in the low twenty-dollar per ton range. Neither of these are mentioned as alternatives, although they are likely candidates for an RFP response. 1700

Alternate technologies and strategies are not at this time true alternatives to Sunshine as proposed. The use of Alternate Daily Cover materials is not an "alternative" to a landfill. The City is proud of its present policy of not sending any Yard Trimmings to landfills, not for disposal, and not for "exposed disposal" as ADC. The use of foam or old, chipped tires for ADC has not been proven to be environmentally sound, even though allowed by the CIWMB. LASER opposes the use of ADC, with the possible use of tarps in conjunction with frequent cover soil applications. The City and the County disagree once again on this policy. With the present rate of diversion in Los Angeles, it does not need this excuse to artifically inflate its figures. 1701

Blind Canyon and Elsmere may still appear in the *Countywide Siting Element*, but they are remote possibilities at this time. 1702

VIII. ADDITIONAL CONCERNS

The question of whether to allow the project as proposed has been answered. The close proximity of the landfill to sensitive areas such as a park and 1703

single-family residential areas must be taken into account. The Granada Hills community has borne the brunt of this landfill for many years. The answers for the City portion are clear; it is not the responsibility of the City to accept the severe negative impacts of landfill dust on frequent windy days, nor of greenhouse gases, nor of high traffic counts, nor of decreased property values that come from having to disclose the landfill's existence, in order to accomodate the high rate of North County growth and its impacts on solid waste generation. That responsibility lies squarely with the County. If landfill space cannot be found then either growth must be controlled or alternatives must be found which are environmentally sound. LASER believes landfills and people simply do not mix.

The needs of the City with regard to landfill space are seen with the present rate of disposal. Permitting a 5,000 tpd landfill when then City has little need for such disposal would be harmful to the interests of the City. It would discourage competition, which is vital if a monopoly on waste disposal is to be avoided. Alternatives to landfills can never develop unless the economics of the marketplace will allow them. Keeping the tipping fees low to entice the City discourages their development, and discourages recycling and source reduction as well. 1704

As has been shown earlier in this response, this is not merely a request for a 5,000 tpd facility—or of even an 11,000 tpd facility, as BFI would have us believe. Rather, approving the project as proposed is in reality allowing a facility of up to 22,500 tpd. If the applicant has made, or is about to make, the required traffic improvements along San Fernando Road, this can become a reality. Therefore, BFI is requested to clarify where it stands on the status of these traffic improvements. 1705 1706

Landfill Alternatives Save Environmental Resources (LASER) appreciates this opportunity to respond.

Respectfully submitted,

Barbara A. Fine

Dear Mr. Plafkin,

Comments regarding Sunshine Canyon Landfill
Draft SEIR 91-0377-ZC/GPA

I am a resident adjacent to the proposed extension into the City of Los Angeles of the Sunshine Canyon Landfill Project. I am writing to comment on the SEIR and oppose the project. 1707

Browning Ferris Industries owns property within Los Angeles County called the East Canyon Dedication Area that is already zoned for the expansion of landfill activities and I feel that it is unnecessary to change the Open Space zoning to allow the proposed landfill to come within 2500 feet of our homes. I bought my property in June 1990 based on the knowledge that the landfill would soon be closing and moving further west into the county area. I feel that it is unfair to expect the residents to accept the Open Space zoning to be changed just so BFI can make more money. 1708

By the Granada Hills-Knollwood Community Plan this property is zoned Open Space which is to "be preserved and conserved from encroachment by inconsistent uses" refer to page 4-230. I can't think of a more inconsistent use than heavy industrial which is being requested. This area was declared Open Space in an agreement with the City of Los Angeles when they operated from 1966 to 1991. On page 4-249 of their SEIR they admit they are creating land use conflicts with the residential use in the area. 1709

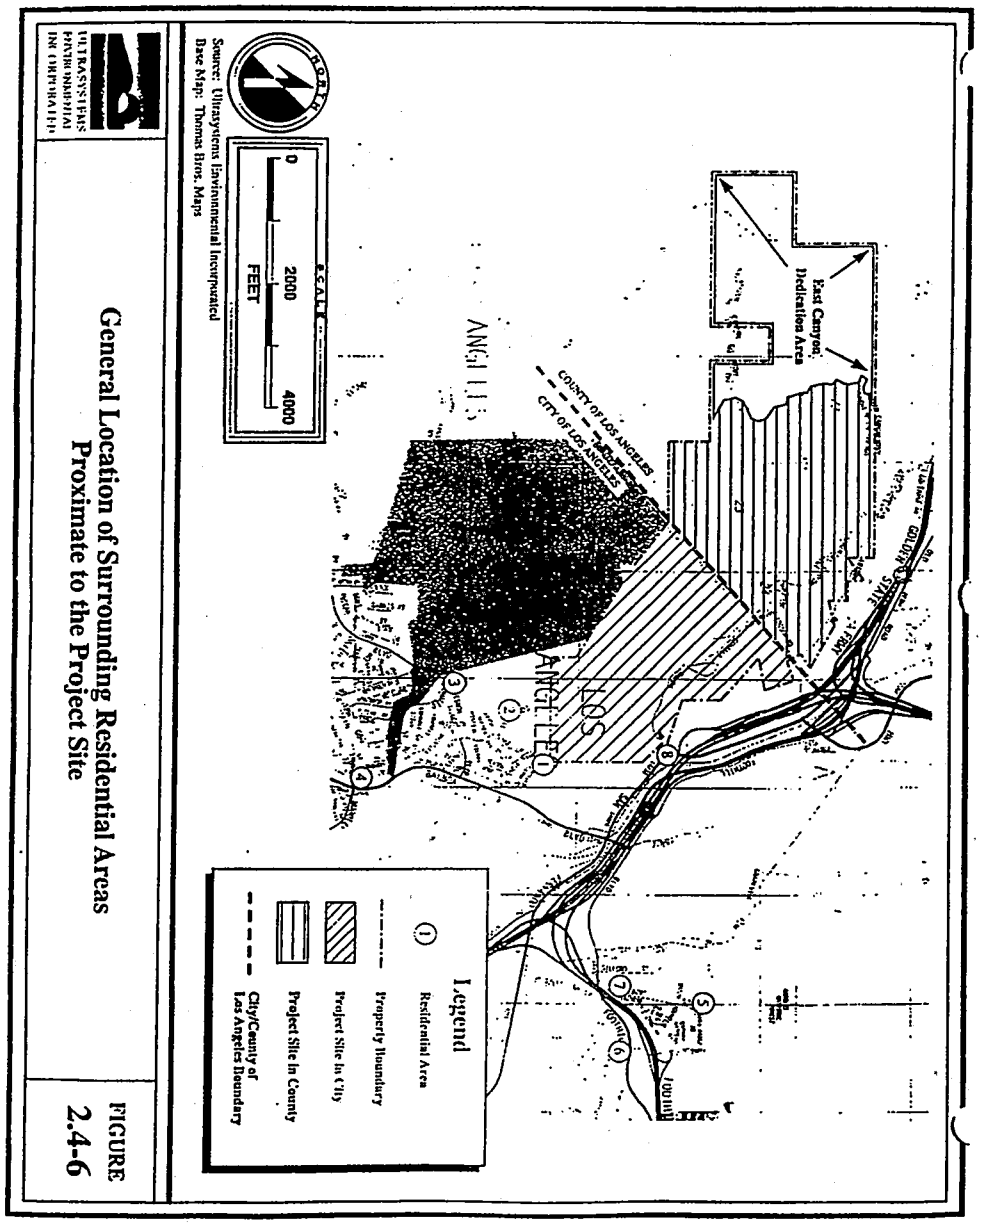
We all can understand the need for landfill sites, BFI has planned to continue landfill operations into the County area. They own additional property which is not being proposed to be used in this 25 year plan. One of the reasons they say they do not want to expand into the 215 acre East Canyon Dedication Area is that it would require removal of 1383 oaks trees, yet in their attachment they would be removing 865 oak trees which they claim they already have a permit for. How did they get a permit to remove oak tress in Open Space ? 1710 1711

We live in an area that is extremely windy. I am very concerned that they are proposing to alter the elevation of the Open Space area from the current 1450 feet to 2000 feet elevation. This would make the 192 acres in the City almost the same elevation as the ridge line. I feel this will greatly alter the wind patterns that come from the north. Now the ridge acts as a wall to block the wind, with them filling this area up it will direct all of the wind over the ridge. On page 4-47 of their SEIR they greatly miss discussing the heavy wind speeds in our area. They generalize with a discussion of the wind throughout the City. They claim the wind only blows from 11 am to 5 pm and admit that the measurement of 45 mph for one hour does not include high Santa Ana conditions ! 1712 1713

So what is the maximum wind speeds they have seen ? They claim to measure it and also admit that several times a year they have to shut down due to heavy winds. Why did they arbitrarily use 45 mph ? How is their operations contributing to the dust in our area ? 1714 1715

On the EIR Summary Sheet and page 1-7 they admit that there are unavoidable adverse impacts due to the dust in the area. There will also be exposure to odors from the landfill and "noise levels adversely impacting adjacent residential areas". Yet they claim this will not affect our property value. 1716 1717 1718

On page 6 of the addendum they state "since the landfill is situated away from major population centers on the City, there are limited environmental impacts upon Los Angeles residents". We are residents of Los Angeles adjacent to this project and they admit we will be adversely affected. Maybe we are a small percentage when you look at the total population of Los Angeles. What if the "limited environmental impacts" are severe to the immediate area. It appears that the adjacent residents are being considered insignificant. 1719 1720



On the same page 6 they state that since this has been a landfill for over 30 years it is ideally suited to continue. Well in 1966 they promised to close in 1991 which allowed for residential expansion adjacent to their property. When is it enough ? 1721

My concern is who verifies the data in the SEIR ? What is the maximum wind speeds they have recorded ? They have conflicting statements regarding the affects on nearby residents. We will be greatly affected and they are trying to gloss it over to get approval. I am recommending that they get approval to expand only in the County area, which is further away from our homes. 1722 ↓ 1724

Sincerely,

Charlotte Rodrigues

General Location of Surrounding Residential Areas
Proximate to the Project Site

FIGURE 2.4-6

Mountains to the north, the Chatsworth-Porter Ranch District to the west, and the Golden State (I-5) and San Diego (I-405) Freeways to the east.[139]

Thirty-five community plans comprise the Land Use Element of the City General Plan. The Granada Hills-Knollwood Community Plan (community plan) is one of those plans. It guides future development of the CPA and promotes an arrangement of land use, circulation, and public services intended to contribute to the economic, social, and physical well-being of community residents. A comprehensive amendment to the plan was approved by the City in July 1996. Subsequent amendments to the Los Angeles Municipal Code (LAMC), as a result of plan revisions, were incorporated as Ordinance No. 171,182. Current plan amendments are designed to protect single-family neighborhoods and provide updated planning policies and practices, protect hillside areas, and ensure adequate transportation and circulation in the CPA. Prior plan updates occurred in November 1974 and August 1987. Those revisions were a result of A.B. 283, which is the General Plan Zoning Consistency Program.[140]

Figure 4.7-2 depicts existing land use designations on the project site and on surrounding areas. The project site in the City is designated "Open Space." The following standards and criteria apply to that designation for privately owned land:

> The Open Space designation for privately owned land is to protect and preserve natural resources and natural features of the environment, such as wildlife refuge and preservation areas; to encourage the management of private lands in a manner which protects the environmental characteristics; and to conserve large parcels which are essentially unimproved. The A1-1 Zone is the intended corresponding zone for privately owned property.[141]

The Granada Hills-Knollwood Community Plan also indicates that

> Open Space areas be preserved and conserved from encroachment by inconsistent uses. Natural waterways should be preserved and maintained as natural open space whenever possible. A buffer zone should support native vegetation and be at least 100 feet from the top of the channel bank. Trails should be designated to be outside this buffer zone as much as possible. Access within these areas should prohibit off-road vehicles and motor bikes by fencing.[142]

The plan's land use map includes the following footnote regarding the project site:

> Under Case No. ZA-17804 (Zone Variance) approved April 18, 1966, the site was granted a variance to permit the continued operation of the dump facilities based upon certain terms

ATTACHMENT

II.F. The information utilized was obtained from the Oak Tree Report prepared for the Sunshine Canyon Landfill Extension FEIR, located in the City and County of Los Angeles.

Approximately 865 existing Coastal Live Oaks would be removed from the proposed project site. The trunk diameters would consist of the following estimated averages, in percentage form:

less than 12"	37%
12" - 18"	48%
18" - 24"	11%
24" - 36"	3%
greater than 36"	>1%

The removal of the 865 Coastal Live Oaks was based upon the oak tree sampling prepared for the FEIR County Oak Tree Report.

II.G. The number of trees being removed from the project site would be counted at a later date and subsequently located and plotted on a Plot Plan Map. Actual numbers plotted would be based upon a 100% inventory. In addition, appropriate mitigation measures would be developed based upon actual tree removal.

During project implementation, all trees would be counted during the year that they are removed; furthermore, oak tree removal would follow the requirements of the Oak Tree Ordinance No. 153,478 of the City. In addition, the project proponent is proposing to replace oak trees on a 2:1 ratio and implement both an oak tree monitoring and management program.

Table 1.6-1
ESAC'S DETERMINATION REQUIREMENTS

Environmental Topical Issue(s)	Potential Area(s) of Impact/Concern
Earth (Grading, Drainage, and Geologic Hazards)	• The proposed project is located within the boundaries of a hillside study area with possible impacts occurring due to grading and alteration of onsite drainage. • The proposed project is proximal to potentially active fault zones and may be subject to unstable earth conditions and other seismic-related hazards.
Air (Air Quality-Stationary Sources)	• Project development may result in deterioration of ambient air quality due to short-term emissions generated during construction. • Future project residents may be exposed to dust and odors generated by landfilling and related activities proximal to the site.
Plant Life	• The proposed project would result in the removal of existing vegetation on the site.
Animal Life	• The proposed project may result in the conversion and/or disturbance of existing animal habitat onsite and proximal to the site. • The proposed project may result in the disruption of access corridors between habitat areas.
Noise (Stationary Sources)	• Project development may significantly affect noise levels, adversely impacting adjacent residential areas.
Land Use (District Plan)	• The proposed project would result in alteration of existing land use.
Light/Glare (Artificial)	• Project development may result in increased ambient reflectivity and glare from the project site, adversely impacting locations proximal to the site.
Risk of Upset	• Project development may result in the release of hazardous substances in the event of an accident or upset conditions due to the volume of solid waste that may be accepted.
Transportation/ Circulation Driveway/Access	• Project-generated vehicular traffic may contribute to cumulative impacts on local circulation. • The project is also located within a traffic impact area defined by the LADOT.
Public Services	• The proposed project may result in a need for additional fire protection and emergency services.
Energy Conservation	• The proposed project would result in increased consumption of nonrenewable energy resources and should consider potential energy impacts.
Water Conservation	• The proposed project would result in an increase of water use on the project site.
Service System (Storm Drainage)	• The proposed project may have a cumulative impact on the existing service system.
Aesthetics	• The proposed project development may substantially alter the surrounding land use.
Equestrian Issues	• The proposed project is located in a community characterized by equestrian-related activities and may impact use of and views from existing equestrian trails.
Cultural Resources (Archaeological)	• Development of the project site may result in disturbance to prior unrecorded sites potentially containing significant artifacts resources.

SEIR
Sunshine Canyon City Landfill
Extension Project (SEIR 97-0377-ZC/GPA)
City of Los Angeles
Vic. LA-005-44.43

Dear Mr. Plafkin:

Caltrans acknowledges receipt of a copy of the memorandum sent to you by Mr. Robert Takasaki, DOT Senior Transportation Planner referencing the above-named project.

The proposed project consists of the development and operation of a Class III nonhazardous solid waste landfill facility and an on-site green waste/wood waste recycling area on a 205-acre site. The project is contiguous with the previously approved Sunshine Canyon County Landfill Extension project located in the unincorporated County area of Sunshine Canyon and utilizing a common access driveway on San Fernando Road south of the I-5 southbound off-ramp and south of Sierra Highway. 1725

Route 5 in the subject area carries a high volume of truck traffic (13.5 per cent compared to average 5 per cent on interstate routes for California, based on the 1994 Annual Average Daily Truck Traffic count). Therefore, any development plans such as this needs to take into consideration the increased volume of large trucks entering and exiting the freeway.

We have the following recommendations:

1) Truck turning radii should be determined based on Interstate Truck Turning Templates for the following locations:

   - N/B Route 5 off-ramp (diamond) onto Roxford Street (westbound)
   - The dual left-turn lanes from westbound Roxford Street going onto S/B Route 5 on-ramp 1726

2) Investigation needs to be conducted to increase curb returns (if needed) at the following locations:

   - Right-turn lane on S/B Route 5 off-ramp at Roxford Street going onto Sepulveda Blvd.
   - Lane coming from Sepulveda Blvd. (eastbound) onto S/B Route 5 on-ramp
   - Right-turn lane on S/B Route 5 off-ramp (cloverleaf) going onto Roxford Street (westbound)

Thank you for the opportunity to have commented on the project. If you have any questions, please call the undersigned at (213) 897-4429 and refer to our IGR/CEQA #971209/NP.

Sincerely,

STEPHEN J. BUSWELL

Re: IGR/CEQA #980230/NP
Revised Mitigation Concept Plan
For the Roxford Street (I-5 SB on-off ramps
And Encinitas Avenue)
Sunshine Canyon Landfill Project
City of Los Angeles
Vic. LA-005-44.43

Dear Mr. Plafkin:

We have received and reviewed the Revised Mitigation Concept Plan for the Roxford Street (I-5 SB on-off ramps and Encinitas Avenue) sent by Betty Lindsay of Ultra Systems Environmental Incorporated.

Our review of the concept plan indicates:

1) Turning will be difficult to negotiate without climbing the curb on the north side of Roxford. 1727
2) Trucks using the northerly left-turn pocket may successfully negotiate the left turn as long as no one is also turning from the southerly left-turn pocket. Trucks using the southerly pocket cannot negotiate the left-turn without climbing the S/E curb return at the S/B on-ramp.
3) The right-turn from S/B off-ramp to Sepulveda Boulevard is too "tight" for trucks to negotiate.
4) The increase of the curb return radius will work (barely).
5) (Isn't this a diamond-shaped ramp, rather than cloverleaf?) The left-turn can be negotiated as long as vehicles aren't waiting at the southerly left-turn pocket (W/B Roxford to S/B I-5 on-ramp).

Thank you for the opportunity to have commented on the project. If you have any questions, please feel free to contact the undersigned at (213) 897-4429 and refer to our **IGR/CEQA #980230/NP.**

REVISED AND UPDATED INFORMATION

APPENDIX D1

LADOT Comments (February 26, 1998), Revised Mitigation Concept Plan and Summary of Freeway Segment Analysis

FORM GEN. 160A (Rev. 1/82)

CITY OF LOS ANGELES

INTER-DEPARTMENTAL CORRESPONDENCE

San Fernando Rd
& Sunshine Canyon
Landfill Access Rd

Date: February 26, 1998

RECEIVED

MAR 0 6 1998

ULTRASYSTEMS
ENVIRONMENTAL

To: Hadar Plafkin, City Planner
Department of City Planning

Robert T. Takasaki

From: Robert T. Takasaki, Senior Transportation Engineer
Department of Transportation

Subject: **REVISED DEPARTMENT OF TRANSPORTATION COMMENTS ON JULY 1997 SUBSEQUENT ENVIRONMENTAL IMPACT REPORT FOR PROPOSED SUNSHINE CANYON CITY LANDFILL EXTENSION PROJECT (SEIR 97-0377-ZC/GPA)**

Reference is made to our November 25, 1997 memo to your Department in which the Department of Transportation (DOT) submitted comments on the July 1997 Subsequent Environmental Impact Report (SEIR) for the Sunshine Canyon City Landfill Extension Project. Upon further consideration and based on a recent meeting between DOT, Department of City Planning and representatives for the Sunshine Canyon Landfill Extension Project and Browning-Ferris Industries (BFI), DOT would like to change our previous comments regarding the improvement plans for the intersection of San Fernando Road and the project driveway. Previously our Department recommended that a new traffic signal and the Ultimate Improvement Plan (dual northbound left turn lanes)be required as the mitigation measure for this location. BFI is now processing a B-Permit to install a new traffic signal at this location to improve the safety of trucks currently using the project driveway to access the County landfill portion of the site.

DOT now recommends that either of the two Interim Improvement Plans (single northbound left turn lane on San Fernando Road at the project driveway depicted in the Conceptual Mitigation Plans contained in Appendix F) may be installed initially at this location. However, if found warranted by DOT within 5 years after the City portion of the landfill begins operations, the developer shall install the Ultimate Improvement Plan (dual northbound left turn lanes) at this location. The developer shall guarantee by a surety bond or other suitable financial instrument acceptable to the Bureau of Engineering, all costs associated with the design and installation of the Ultimate Improvement Plan (dual northbound left turn lanes including the widening of the San Fernando Road and project driveway).

The developer shall also commence processing a B-Permit with the Bureau of Engineering for the Ultimate Improvement Plan within 60 days after the City portion of the landfill begins operation to insure that the Ultimate Improvement Plan can be installed immediately after DOT determines that such improvements are needed. Prior to setting the bond amount the Bureau of Engineering shall require that the developer's engineer or contractor contact DOT's B-Permit Coordinator, telephone (213) 580-5336, to arrange a pre-design meeting to finalize the proposed design needed for the project.

If any questions should arise, please contact John Sam of my staff at (213) 580-5206.

Revisions to Draft SEIR, Section 4.2, Air Quality

4.2 AIR QUALITY

FEIR DOCUMENTATION

The following list references specific volumes, sections, and page numbers of the certified FEIR and its incorporated technical documentation that provide background information and technical analyses relevant to the topical issue of air quality. Development of the proposed project, including the additional ±42 acres located in County jurisdiction, has been previously addressed within the context of ~~this~~ the certified County FEIR and approved for development pursuant to County Landfill CUP conditions. Any new potential air quality impacts associated with this area (i.e., ~~the proposed project and the~~ relocation of ancillary facilities and environmental protection and control systems onto City lands) ~~will be~~ have been addressed in ~~the Draft SEIR~~ this Final SEIR.

ENVIRONMENTAL SETTING

4.2.1 Existing Conditions

The proposed project is located in the City and County of Los Angeles within the South Coast Air Basin (SCAB). The SCAB is a 6,600-square-mile area that encompasses Los Angeles County, Orange County, the nondesert portions of Riverside County, and the western portion of San Bernardino County. The SCAB is comprised of a coastal plain with connecting broad valleys and low hills bounded by the Pacific Ocean to the southwest, the San Gabriel Mountains to the north, the Santa Ana Mountains to the south, and the San

Bernardino and San Jacinto Mountains to the east. The region lies in the semipermanent, high-pressure climatic condition of the eastern Pacific zone. The entire SCAB is under the jurisdiction of the South Coast Air Quality Management District (SCAQMD).

4.2.2 California's SCAB Regional Climatic Characteristics

Meteorological conditions are important to air quality because atmospheric parameters, including wind speed and direction, temperature, temperature inversions, and topography, significantly influence air contaminant dispersion and ground-level concentrations.

Climate. The distinctive climate of the SCAB is determined by terrain and geographical location. The SCAB has a Mediterranean climate characterized by mild winters when most rainfall occurs, and warm, dry summers. The most important climatic and meteorological characteristics influencing air quality in the project area are the persistent temperature inversions, predominance of onshore winds in Los Angeles County, mountain ridge and valley topography, and prevalent sunlight.

The mountains that frame the SCAB range in elevation from approximately 6,000 to 11,500 feet above mean sea level (MSL). The topography of the SCAB is a major contributing factor to the observed air quality and air pollution levels. During the daytime, prevailing coastal winds blow inland, and air masses subsequently become blocked by the surrounding mountain ranges. As a result, the restricted airflow makes the SCAB highly susceptible to air pollutant accumulation. With very light average wind speed, the air basin has a limited capability to disperse air contaminants horizontally.

Temperature. With the exception of mountain locations, the annual average temperature (averaging 62°F) within the SCAB varies little throughout the 6,600-square-mile air basin; however, with a less pronounced oceanic influence, the eastern portion shows greater variability in annual minimum and maximum temperatures. The City of San Bernardino, for example, has an annual average temperature range from 37 to 97°F, while the City of Santa Monica has an annual range between 47 to 75°F, and Burbank, ranges from 42 to 87°F. All portions of the SCAB have had recorded temperatures well above 100°F in recent years. January is usually noted as the coldest month, and July and August are usually the hottest months throughout the year.

Temperatures at the project site can be inferred from data published by the SCAQMD (January 1980). An SCAQMD monitoring station is located at 24875 San Fernando Road in Newhall and may be generally considered to be representative of the project area. Temperatures at this monitoring station range between 42 and 93°F, and recorded minimum and maximum temperatures of 23 and 113°F, respectively, have been measured.

Precipitation. Practically all of the annual rainfall in the SCAB occurs between the months of November and April. Summer rainfall normally is restricted to widely scattered thundershowers near the coast and slightly heavier shower activity in the air basin's easterly area and over the mountains. Annual average rainfall varies from 9 inches in Riverside to 14 inches in downtown Los Angeles, but higher amounts are measured at local foothill locations (e.g., Pacoima area has an average rainfall of 19.04 inches).[1] Monthly and yearly rainfall totals are extremely variable. Rainy days vary from 5 to 10 percent in the SCAB with the frequency of such days being higher near the coast.

1/ South Coast Air Quality Management District (SCAQMD). 1980.

Humidity. Although the SCAB has a semiarid climate, the air near the ground surface is surprisingly moist because of the presence of a shallow marine layer. Except for infrequent periods when dry, continental air is brought into the air basin by offshore winds, this shallow marine layer is an important modifier of the Basin's climate. Periods with heavy fog are frequent, and low stratus clouds (sometimes referred to as "high fog") are a characteristic climate feature. Humidity is typically at a minimum during the winter months and peaks in the months of September and October. Annual average relative humidity is about 70 percent at the coast and approximately 57 percent in the eastern part of the SCAB. The Van Nuys area has an average humidity of about 63 percent.[2]

Wind. With very light average wind speeds, the SCAB's atmosphere has a limited capability to disperse air contaminants horizontally. For example, wind speeds in downtown Los Angeles average about 5.7 miles per hour with little seasonal variation. Summer wind speeds average slightly higher than winter wind speeds. Inland areas record slightly lower wind speeds than downtown Los Angeles, while coastal wind speeds average about 2 ~~miles per hour (~~mph~~)~~ higher than downtown Los Angeles. The dominant daily wind pattern is a daytime sea breeze and a nighttime land breeze. This regime is broken only by occasional winter storms and infrequent strong northeasterly Santa Ana flows from the mountains and deserts north of the SCAB. The dominant wind patterns in the SCAB are shown on **Figure 4.2.1**.

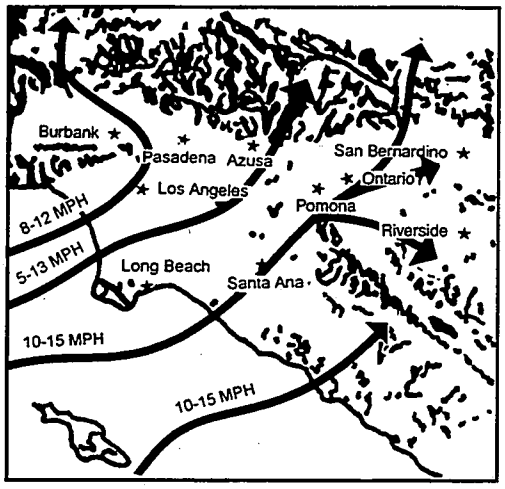
On most spring and early summer days, the daily air pollutants produced within the SCAB are moved out of the air basin through mountain passes or are lifted upward by the warm, vertical currents produced by the heating of mountain slopes. In those seasons, pollutants within the SCAB are dispersed and transported (often to a distance of 60 miles or more) by ocean air currents during the afternoon. From late summer through the winter months, this flushing is less pronounced because of lighter wind speeds and the earlier appearance of offshore winds. This trend is observed on **Figure 4.2-2** where it is noted that the wind blows from a southerly direction about half the time with an average speed of less than 6 mph. With extremely stagnant windflow in the Basin, offshore drainage winds begin in the late afternoon near the mountains. During the winter months, the project area also experiences a frequent flow from the north and northwest through the Newhall Pass into the western San Fernando Valley. These winds predominate between 11:00 AM and 5:00 PM. The speeds (16.5 mph average) reflect the influence of Santa Ana winds, which are strongest during those hours of the day and blow in a similar direction.

Onsite measurement has shown the overall average wind speed to be 9.9 mph with a maximum 1-hour measurement of 45 mph. It should be noted that the overall average wind speed and maximum 1-hour wind speed do not preclude the presence of very low or high wind speeds, especially during Santa Ana conditions. These Santa Ana conditions, which are prevalent in Southern California from the fall through spring, with an average 5 to 10 occurrences per year, can create strong southern-flowing winds.

Cloudiness. The presence of clouds is a contributing factor to air quality, considering the necessary role of sunshine in the process of producing photochemical smog. Because of persistent low inversions and cool coastal ocean water, morning fog and low stratus clouds are common in coastal areas, with decreasing concentrations inland. On average, there are 187 clear days (i.e., 0 to 30 percent of the sky obscured by clouds), 102 partly cloudy days (i.e., 40 to 70 percent cloud cover), and 76 cloudy days (i.e., 80 percent to full cloud cover). Cloudiness is slightly less in the eastern portions of the air basin and about 25 percent greater along the coast.

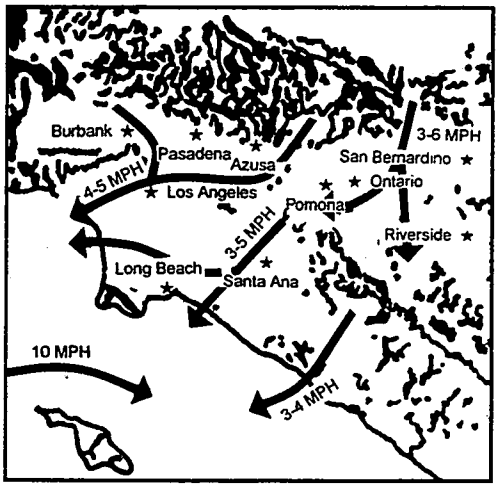
---

[2]/ Ibid.



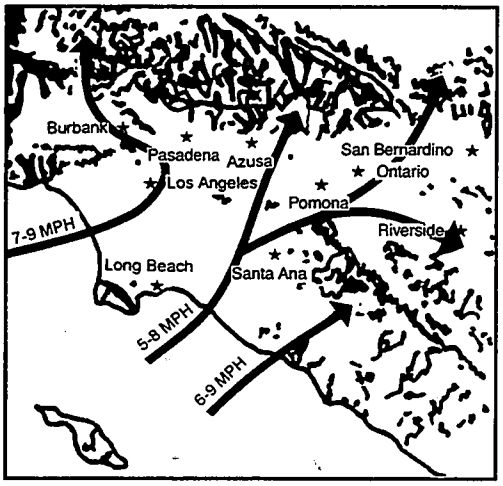
Inversions. The vertical dispersion of air pollutants in the SCAB is hampered by the presence of a persistent temperature inversion in the layers of the atmosphere near the surface of the earth. Because of expansional cooling, temperatures usually decrease with altitude. A reversal of this atmosphere condition, where temperature increases with altitude, is termed an inversion. Inversions can exist at the surface or at any height above the ground. The height of the base of the inversion at any given time is known as the "mixing height."

The mixing height can change under conditions when the top of the inversion does not change. Usually, inversions are lower before sunrise than during the daylight hours. Mixing heights normally increase as the day progresses (the sun warms the ground, which in turn warms the surface air layer). As this heating continues, the temperature of the surface layer approaches the potential temperature of the base of the inversion. When these temperatures become equal, the inversion layer begins to erode at its lower edge. If enough warming takes place, the inversion layer becomes weaker and finally "breaks." The surface air layers can then mix upward without limit. This phenomenon is frequently observed in the middle to late afternoon on hot summer days when the smog appears to clear up suddenly. Winter inversions frequently break up by midmorning, thereby preventing contaminant buildup during these periods.



The net input of pollutants in the atmosphere from both mobile and stationary emission sources varies little by season. Pollutants enter the surface air layers and can mix with less contaminated air from anywhere below the inversion base. The contaminants in the surface layer tend to diffuse and form a relatively uniform mixture (in some cases higher concentrations exist immediately below the inversion base) all the way up to the mixing height. These contaminants cannot, however, rise through the inversion. As a result, these air pollutants become more and more concentrated unless the inversion layer lifts or is broken or unless surface winds are strong enough to disperse the pollutants horizontally. The combination of low wind speeds and low inversions produces the greatest concentration of pollutants. On days of no inversion or when winds average over 15 mph, there is little likelihood of any significant smog effects.

In the summer, the longer daylight hours and the brighter sunshine combine to cause a reaction between hydrocarbons (HC) and oxides of nitrogen, thereby forming photochemical smog. (Note: for purposes of this analysis, HC, reactive organic gases [ROG], and volatile organic compounds [VOC] are used synonymously.) In the winter, the greatest pollution problems are carbon monoxide (CO) and oxides of nitrogen because of extremely low inversions and air stagnation during the late night and morning hours. CO is not as great a problem in summer because inversions are not as low and intense in the surface boundary layer (within 100 feet of the ground) and because horizontal ventilation is better in summer than during the winter. The higher summer inversions, however, are typically stronger and last until much later in the day.



Along the Southern California coast, surface air temperatures are relatively cool. The resultant shallow layer of cool air at the surface, coupled with warm, dry subsiding air from aloft produces early morning inversions on about 87 percent of the days. The SCAB-wide average occurrence of inversions at the ground surface is 11 days per month. The averages vary from 2 days in June to 22 days in December and January. Higher inversions, but less than 2,500 feet above sea level, occur 22 days each month on an average of 25 days in June and July to 4 days in December and January. Restricted maximum mixing heights of 3,500 feet above MSL or less average 191 days each year.

FIGURE 4.2-2

The potential for high concentrations varies seasonally for many contaminants. During late spring, summer, and early fall, light winds, low mixing heights, and brilliant sunshine combine to produce conditions favorable for the maximum production of photochemical oxidants, mainly ozone (O_3). During the spring and summer, when fairly deep marine layers are frequently found in the SCAB, sulfate concentrations are at their peak. When strong inversions are formed on winter nights and couple with near-calm winds, CO from automobile exhausts becomes highly concentrated. The highest yearly values for CO are generally measured during November, December, January, and February.

4.2.3 Criteria Air Pollutants

The quality of the ambient air is affected by pollutants emitted into the air from stationary and mobile sources. Stationary sources can be divided into two major subcategories: point sources and area sources. Point sources consist of one or more emission sources at a facility with an identified location and are usually associated with manufacturing and industrial processing plants. Area sources are widely distributed and produce many small emissions.

Mobile sources refer to emissions from motor vehicles, including tailpipe and evaporative emissions, and are classified as either on-road or off-road. On-road sources are a combination of emissions from automobiles, trucks, and indirect sources. Indirect sources are sources that by themselves may not emit air contaminants; however, they indirectly cause the generation of air pollutants by attracting vehicle trips or consuming energy. Examples of indirect sources include an office complex or commercial center that generates commuter trips and consumes energy resources through the use of electricity for lighting and space heating. Indirect sources also include actions proposed by local governments, such as redevelopment districts and private projects involving the development of either large buildings or tracts. In addition, indirect sources include those emissions created by the distance vehicles travel. Off-road sources include aircraft, ships, trains, and self-propelled construction equipment.

The air pollutants emitted into the ambient air by stationary and mobile sources are regulated by federal and State law. These regulated air pollutants are known as "criteria air pollutants" and are categorized as primary and secondary pollutants. Primary criteria air pollutants are those that are emitted directly from sources. CO; ROG; nitrogen oxide (NO_x); sulfur dioxide (SO_2); and most fine particulate matter (PM_{10}), ~~including~~ that are found in lead (Pb) and fugitive dust; are primary criteria air pollutants. Secondary criteria air pollutants are those pollutants formed by chemical and photochemical reactions in the atmosphere. O_3 and nitrogen dioxide (NO_2) are the principal secondary pollutants.

Presented below is a description of each of these primary and secondary criteria air pollutants.

Carbon Monoxide. CO is a colorless, odorless, toxic gas produced by incomplete combustion of carbon substances (e.g., gasoline or diesel fuel). The primary adverse health effect associated with CO is the interference of normal oxygen transfer to the blood, which may result in tissue oxygen deprivation.

Reactive Organic Gases. ROGs are compounds comprised primarily of atoms of hydrogen and carbon. Internal combustion associated with motor vehicle usage is the major source of HC. Adverse effects on human health are not caused directly by ROG but rather by reactions of ROG to form secondary pollutants.

Nitrogen Oxides. NO_x serve as integral participants in the process of photochemical smog production. The two major forms of NO_x are nitric oxide (NO) and NO_2. NO is a colorless, odorless gas formed from atmospheric nitrogen and oxygen when combustion takes place under high temperature and/or high pressure.

NO_2 is a reddish-brown irritating gas formed by the combination of NO and oxygen. NO_x acts as an acute respiratory irritant and increases susceptibility to respiratory pathogens.

Sulfur Dioxide. SO_2 is a colorless, pungent, irritating gas formed by the combustion of sulfurous fossil fuels. Fuel combustion is the primary source of SO_2. At sufficiently high concentrations, SO_2 may irritate the upper respiratory tract. At lower concentrations and when combined with particulates, SO_2 may do greater harm by injuring lung tissue.

Particulates. Particulates consist of finely divided solids or liquids such as soot, dust, aerosols, fumes, and mists. About 90 percent by weight of all emitted particles are greater than 10 microns (i.e., 10 one-millionths of a meter or 0.0004 inch) in diameter; however, about 90 percent of the total number of particulates are smaller than 5 microns. Particulate discharge into the atmosphere results primarily from industrial, agricultural, construction, and transportation activities. Particulates may adversely affect the human respiratory system, especially in those people who are naturally sensitive or susceptible to breathing problems.

Fugitive Dust. Fugitive dust poses primarily two public health and safety concerns. The first concern is that of respiratory problems attributable to the suspended particulates in the air. The second concern is that of motor vehicle accidents caused by reduced visibility during severe wind conditions. Fugitive dust may also cause significant property damage during strong windstorms by acting as an abrasive material agent (much like sandblasting activities).

Ozone. O_3 is one of a number of substances called photochemical oxidants that are formed when reactive organic compounds (ROC)[3] and NO_x (both byproducts of the internal combustion engine) react with sunlight. O_3 is present in relatively high concentrations in the SCAB, and the damaging effects of photochemical smog are generally related to the concentrations of O_3. O_3 may pose a health threat to those who already suffer from respiratory diseases. However, O_3 also affects healthy people. In the past, those effects were thought to be limited to more difficult breathing during work and exercise. However, research now indicates that children in the SCAB experience a 10- to 15-percent loss in lung function. The SCAB has peak O_3 levels two and a half times higher than the federal health standard and three times higher than the more stringent State standard.

Nitrogen Dioxide. NO_2 is a byproduct of fuel combustion. The principal form of NO_2 produced by combustion is NO, but NO reacts quickly to form NO_2, creating the mixture of NO and NO_2 commonly called NO_x. NO_2 acts as an acute irritant and, in equal concentrations, is more injurious than NO. At atmospheric concentrations, however, NO_2 is only potentially irritating. There is some indication of a relationship between NO_2 and chronic pulmonary fibrosis. Some increase in bronchitis in children (2 and 3 years old) has also been observed at concentrations below 0.3 part per million (ppm). NO_2 absorbs blue light; the result is a brownish-red cast to the atmosphere and reduced visibility. NO_2 also contributes to the formation of PM_{10} (particulates having an aerodynamic diameter of 10 microns or 0.0004 inch or less in diameter).

3/ In SCAQMD documents, the inclusive term "reactive organic compounds" generally describes and is gradually replacing the separate terms reactive organic gases (ROG), volatile organic compounds (VOCs), and hydrocarbons (HC), except in cases where such separation provides additional clarification and definition. For purposes of this analysis, these terms are used synonymously.

4.2.4 Ambient Air Quality Standards and Annual Statistics

The federal Clean Air Act (CAA) established the National Ambient Air Quality Standards (NAAQS) and the California Air Resources Board (CARB) established the California Ambient Air Quality Standards (CAAQS) to reflect the maximum levels of the respective air pollutants permissible to avoid adverse health and welfare effects. NAAQS have been established for six ambient air pollutants (i.e., SO_2, Pb, CO, NO_2, O_3, and PM_{10}). In contrast, California has established CAAQS for other pollutants, imposed more stringent standards, and established different exposure periods than those presented ~~those~~ in the NAAQS. The federal and State standards are presented in **Table 4.2-1**.

Existing Air Quality

The CARB monitors air pollutants at more than 200 locations throughout the State and publishes these data on a regular basis. Existing levels of ambient air quality and historical trends and projections in the project area are best represented by measurements made by the SCAQMD at its Santa Clarita air monitoring station located at 24875 San Fernando Road in Newhall, which is the nearest monitoring station to the project site and, like the project site, is also located within the Newhall Pass. Monitored air pollutants include O_3, CO, NO_2, SO_2, and PM_{10}. These measurements have shown that photochemical smog levels (mainly O_3) are high in summer, dust levels may exceed particulate standards throughout the year, and primary vehicular pollutant levels (e.g., CO and NO_2) are very low in the area. **Table 4.2-2** summarizes the last ~~5~~ 7 years of published data for the Santa Clarita station.

The federal O_3 standard is exceeded approximately ~~65~~ 50 days per year and is the pollutant of most concern in the SCAB. Although there are no exceedances of the NO_2 standards, NO_x is a precursor to O_3 formation. O_3 is the result of a chemical reaction between ROG and NO_x emissions in bright sunlight. HC and NO_x are emitted by both mobile and stationary sources, with the greater portion emanating from mobile sources in the SCAB. Pollutants emitted from the upwind areas react during their transport downwind to produce the O_3 concentrations measured at the Santa Clarita monitoring station. As a result, all upwind areas within the SCAB and portions of the Southeast Desert Air Basin contribute to the O_3 production. These concentrations increase during the summer, with daily concentrations increasing from the late morning through the afternoon.

With regard to particulate matter, monitoring for this criteria pollutant only began in 1989; therefore, it is difficult to determine the existence of a regional trend. The State standard for PM_{10} was exceeded at the Santa Clarita station during ~~69~~ 87 of the ~~289~~ 403 monitoring events (~~24~~ 22 percent) in the last ~~5~~ 7 years. The federal standard has not been exceeded since monitoring began at this station.

Suspended particulate matter is a mixture of natural and manmade materials including soil particles, biological materials, sulfates, nitrates, organic compounds, and Pb. High dust levels result from strong winds acting on loose arid soils. This is evidenced by the fact that airborne particulate exceedances are strongly correlated with the frequency of desert windstorms. Much of this dust burden is in the form of large, heavy particles that settle out of the air in proximity to their origin.

These larger particles are filtered out by the respiratory system and pose more of a nuisance than a health threat. Smaller particles (PM_{10}) are created by the combustion of fossil fuels but are also given off from tire wear and brake dust, as well as windblown dust.

Table 4.2-1
STATE AND FEDERAL AMBIENT AIR QUALITY STANDARDS

Table 4.2-1(Cont.)
STATE AND FEDERAL AMBIENT AIR QUALITY STANDARDS

Notes:

1. California standards for O_3, CO, SO_2 (1-hour), NO_2, and PM_{10} suspended particulate matter are values that are not to be exceeded. The sulfates, lead, and visibility reducing particle standards are not to be equaled or exceeded.
2. National standards, other than O_3 and those based on annual averages or annual arithmetic means, are not to be exceeded more than once a year. The O_3 standard is attained when the expected number of days per calendar year with maximum hourly average concentrations above the standard is equal to or less than one.
3. The concentration is expressed first in units in which it was promulgated. Equivalent units given in parentheses are based on a reference temperature of 25°C and a reference concentration of 760 millimeters (mm) of mercury (1,013.2 millibar); ppm in this table refers to parts per million by volume, or micromoles of pollutant per mole of gas.
4. Any equivalent procedure that can be shown to the satisfaction of the CARB to give equivalent results at or near the level of the air quality standard may be used.
5. National Primary Standards: The levels of air quality necessary, with an adequate margin of safety, to protect the public health. Each state must attain the primary standards no later than 3 years after that state's implementation plan is approved by the USEPA.
6. National Secondary Standards: The levels of air quality necessary to protect the public welfare from any known or anticipated adverse effects of a pollutant. Each state must attain the secondary standards within a "reasonable time" after the implementation plan is approved by the USEPA.
7. Reference method as described by the USEPA. An "equivalent method" of measurement may be used but must have a "consistent relationship to the reference method" and must be approved by the USEPA.
8. At locations where the state standards for O_3 and/or suspended particulate matter are violated. National standards apply elsewhere.
9. Prevailing visibility is defined as the greatest visibility attained or surpassed around at least half of the horizon circle but not necessarily in continuous sectors.

* Table prepared in accordance with CARB Fact Sheet 38 (revised 7/88).

All other pollutants, particularly those related to vehicular source emissions such as CO and NO_2, have not exceeded their allowable levels since monitoring began in 1989.

Although major sources of air pollution exist within the Santa Clarita Valley, the data in **Table 4.2-2** suggest that air quality problems in the study area are mainly due to the transport of pollutants into the area from upwind sources. Because the area is subject to frequent violations of both the State and federal air quality standards for O_3 and State standards for PM_{10}, the project area is very sensitive to additional O_3 precursor and particulate pollutant (PM_{10}) emissions.

4.2.5 Air Quality Management Plan

The SCAQMD and the Southern California Association of Governments (SCAG) are the agencies responsible for preparing the Air Quality Management Plan (AQMP) for the SCAB. Since 1979 a number of AQMPs have been prepared. The most recent adopted comprehensive plan, at the time that this air quality assessment was completed, is the 1994 Air Quality Management Plan (1994 AQMP), which includes a variety of strategies and control measures. Recently, the 1997 AQMP was adopted by the SCAQMD and has been approved by the CARB. This plan has not yet received final approval from the United States Environmental Protection Agency (USEPA) as part of the State Implementation Plan revision. The 1994 AQMP was based on the 1991

Notes:

1. With the exception of inhalable particulates (PM_{10}), all values are based on 365 days per year.
2. Less than 12 full months of data and may not be representative.
3. NM - Not Monitored, monitoring discontinued.
4. Violations per number of samples.

AQMP and was designed to comply with State and federal requirements, reduce the high level of pollutant emissions in the SCAB, and ensure clean air for the region through the control measures detailed below. To accomplish its task, the 1991 AQMP relied on a multilevel partnership of governmental agencies at the federal, State, regional, and local level. These agencies (i.e., U.S. Environmental Protection Agency [USEPA], CARB, local governments, SCAG, SCAQMD) are the cornerstones that implement the 1994 AQMP and previous AQMP programs.

The control measures in the 1991 AQMP are categorized into three tiers: (1) Tier I includes measures that propose currently available technological applications and management practices that can be adopted within the next 5 years, (2) Tier II measures are based on significant advancement of today's technological applications within the next 10 to 15 years, and (3) Tier III requires the development of new technologies that are currently in the research stage and that will be implemented within the next 20 years. In addition, the 1991 AQMP provides an attainment planning framework that sets specific dates by which the SCAB will achieve the federal and State air quality standards as shown in **Table 4.2-3** below.

Table 4.2-3
PROJECTED ATTAINMENT DATES FOR FEDERAL AND STATE AIR QUALITY STANDARDS FOR THE SOUTH COAST AIR BASIN

Air Pollutant	State	Federal
Nitrogen dioxide (NO_2)	December 31, 1999	December 31, 1994
Carbon monoxide (CO)	2000 - 2010	December 31, 1999
Ozone (O_3)	Beyond 2010	December 31, 2009
Particulate matter (PM_{10})	Beyond 2010	December 31, 2005

Source: 1991 AQMP, SCAQMD

The 1991 AQMP was revised in 1994 (1994 AQMP) to satisfy the planning requirements of both the 1990 amendments of the CAA and the California Clean Air Act (CCAA). These requirements are briefly discussed below.

- **Federal Clean Air Act Requirements.** The CAA requires plans to provide for the implementation of all reasonably available control measures "as expeditiously as practicable," including the adoption of reasonably available control technology for reducing emissions from existing sources. Emission control innovations in the form of market-based approaches are explicitly encouraged by the CAA. The SCAQMD is the first local agency in the country to adopt a market-based approach for controlling stationary source emissions of oxides of nitrogen and sulfur and, in accordance with the pending revisions, is proposing additional market-based control measures. Other federal requirements addressed in the revision include mechanisms to track plan implementation and milestone compliance for O_3 and CO.

  In addition, the 1990 amendments to the CAA require the SCAQMD to develop the following demonstrations or plans addressed in the 1994 AQMP: (1) an O_3 attainment demonstration, (2) a post-1996 rate-of-progress demonstration, and (3) a PM_{10} State Implementation Plan (SIP) (required in 1996) that incorporates best available control measures for fugitive sources.

- **California Clean Air Act Requirements.** In addition to federal requirements, the 1994 AQMP meets CCAA requirements. According to the CCAA, air pollution control districts must design their air quality attainment plans to achieve a reduction in basin-wide emissions of 5 percent or more per year (or 15 percent or more in a 3-year period) for all nonattainment pollutants and their precursors. For emission reduction accounting purposes, the CARB has established a 7-year initial reporting period (1988 to 1994) with reporting intervals every 3 years thereafter. As a result, the 1994 AQMP

must seek to achieve a 35-percent reduction for the initial period and a 15-percent reduction for every subsequent interval.

The CCAA also requires that the 1994 AQMP control measures reduce overall population exposure to criteria pollutants, with a 40-percent reduction due by the end of 1997 and a 50-percent reduction by the year 2000. This provision is applicable to O_3, CO, and NO_2 in the SCAB. The CCAA further requires the SCAQMD's Governing Board to determine that the 1994 AQMP is a cost-effective strategy that will achieve attainment of the State standards by the earliest practicable date. In addition, the 1994 AQMP must include an assessment of the cost-effectiveness of available and proposed measures and a list of the measures ranked from the least cost-effective to the most cost-effective. In addition to cost-effectiveness, other factors must be considered, including technological feasibility, emissions reduction potential, rates of reduction, public acceptability and enforceability.

THRESHOLDS FOR DETERMINING SIGNIFICANCE

The *SCAQMD CEQA Air Quality Handbook* identifies a landfill expansion that produces an exceedance of recommended emission thresholds or other secondary significance criteria as a project of potential environmental significance for air quality.[4] The basis for listing landfills as "potentially significant" relates to the generation of potentially significant quantities of mobile source emissions associated with the project's operation. Other "secondary indicators" include the potential for a landfill project to subject sensitive receptors to objectionable odors.

Presented in the *SCAQMD CEQA Air Quality Handbook* are both a methodology for the quantification of project-related air quality impacts and recommended standards to evaluate the significance of those emissions. Based on that document, the following information is presented:

> While § 15064, subd.(b) of the State CEQA Guidelines states that an ironclad definition of a significant effect is not possible because the significance of an activity may vary with the setting, the SCAQMD believes that the setting as referred to in CEQA can be defined in this case. Under State (California) law (Health and Safety Code § 40402), the SCAB is defined as a distinct geographic area with a critical air pollution problem for which ambient air quality standards have been promulgated to protect public health. As such, the District believes that significance thresholds can be established based on scientific and factual data that is contained in the federal and State Clean Air Acts. Therefore, the District recommends that these thresholds be used by lead agencies in making a determination of significance. However, *the final determination of whether or not a project is significant is within the purview of the lead agency* pursuant to § 15064, subd.(b) of the State CEQA Guidelines [emphasis added].

In Chapter 6 of the *SCAQMD CEQA Air Quality Handbook,* the SCAQMD has established two types of air pollution thresholds (i.e., emission thresholds and additional indicators) to assist local governmental agencies in determining whether the projected emissions from operational phase of a project will be significant. As stated in the *SCAQMD CEQA Air Quality Handbook*, "if the lead agency finds that the operational phase of

---

[4] *SCAQMD CEQA Air Quality Handbook*, South Coast Air Quality Management District (SCAQMD), Table 6-2. April 1993.

a project has the potential to exceed either of the air pollution thresholds, the project should be considered significant." Both types of threshold factors are discussed below.

Separate threshold standards have been recommended for assessing construction impacts that are averaged over a 3-month period and include only actual working days.

Emission Significance Thresholds (Primary Effects)

Specific criteria air pollutants have been identified by the SCAQMD as pollutants of special regional concern. Based on this categorization, **Table 4.2-4** lists the following significance thresholds for emissions from these pollutants.

Table 4.2-4
EMISSION SIGNIFICANCE THRESHOLDS

Pollutant	Construction Criteria (lb/day)	Construction Criteria (tons/qtr)	Operational Criteria (lb/day)
CO	550	24.75	550
NO_x	100	2.5	55
ROG	75	2.5	55
SO_x	150	6.75	150
PM_{10}	150	6.75	150

Source: *SCAQMD CEQA Air Quality Handbook*, Chapter 6.

Note: The *SCAQMD CEQA Air Quality Handbook* does not list daily construction criteria for SO_x. This value is extrapolated from the quarterly criterion.

Projects in the SCAB with daily operation-related emissions that exceed any of the above emission thresholds may be considered significant. Additionally, a project may be significant if vehicle CO emissions cause an exceedance of either the State 1- or 8-hour CO standard.

As indicated in the *SCAQMD CEQA Air Quality Handbook*, "the District considers a project to be mitigated to a level of insignificance if its impact is mitigated below the thresholds defined in Chapter 6 of the *SCAQMD CEQA Air Quality Handbook*."

Additional Indicators (Secondary Effects)

The SCAQMD recommends that "additional indicators" be used as screening criteria with respect to air quality. Relevant additional factors identified in the *SCAQMD CEQA Air Quality Handbook* include the following significance criteria: (1) interference with the attainment of the federal or State ambient air quality standards by either violating or contributing to an existing or projected air quality violation; (2) generation of vehicle trips that cause a CO "hot spot"; (3) creation of or subject receptors to an objectionable odor that requires a 10:1 dilution with fresh air before being no longer detectable; (4) introduction of hazardous materials onsite that could result in an accidental release of air toxic emissions or acutely hazardous

materials posing a threat to public health and safety; (5) emissions of an air toxic contaminant regulated by SCAQMD rules or included on a federal or State air toxic list; (6) the burning of hazardous, medical, or municipal waste as in waste-to-energy facilities; and/or (7) emissions of carcinogenic or toxic air contaminants that individually or cumulatively exceed the maximum individual cancer risk of 10 in 1 million.[5]

ENVIRONMENTAL IMPACT

4.2.6 Proposed Project Overview

The project's air pollutant emissions are comprised of two basic source categories: construction-related or short-term impacts and operational or long-term impacts. Project construction would include initial site excavation and grading activities, including clearing and grubbing of all surficial vegetation, leveling unpaved areas, and site excavation for the landfill base liner system and the installation of the environmental protection and control systems. Construction-related air pollutant emissions are associated with the site preparation and construction phasing of the proposed project and include fugitive dust emissions and exhaust emissions from construction equipment, material delivery trucks, and workers' vehicles.

Long-term air pollutant emissions are generally associated with operational activities that would occur over the site life of the landfill and closure and post-closure maintenance activities that would take place once the landfill ceases landfilling operations. Stationary source emissions are typically generated by the combustion of LFG, daily grading and cover operations, and the offsite generation of electrical energy for onsite use. Mobile source emissions consist of motor vehicle exhaust generated by project traffic. The installation of the liner system and access road realignment, will be performed in sequences as landfill development occurs. Thus, these improvements are considered operational components of the proposed project. Also during the operational phase, portable structures now located at the County Landfill will be relocated onto the City portion of Sunshine Canyon. Construction-related emissions associated with the project, as well as any associated impacts, are addressed below. Long-term (operational) air quality impacts are addressed within the Section 4.2.8, Air Quality Operational Phase (Long-Term).

4.2.7 Site Preparation/Construction ~~Sequencing~~ Phase (Short-Term)

Construction Exhaust Emissions

Diesel-powered, earthmoving vehicles or other heavy equipment would be utilized during the grading and construction sequencing of the proposed City/County Landfill. Information regarding the numbers and types of construction equipment that would be utilized was provided by the project proponent. As a reasonable worst-case scenario, grading operations are expected to occur during a 10-hour workday. Equipment emissions were calculated in accordance with methodology presented in the *SCAQMD CEQA Air Quality Handbook* and are shown in **Table 4.2-5**.

Offsite emissions will be produced by the 70 construction workers who will commute to the site daily. According to the *SCAQMD CEQA Air Quality Handbook*, these work-based trips are projected at 10 miles in each direction. Based on an average speed of 30 mph, two cold starts, and two hot soaks per worker,

5/ Ibid., pp. 6-2 and 6-3.

Notes:

1. Heavy equipment emissions are calculated according to methodologies presented in Table 4.2-7 ~~Based based on Tables A9-8-A, A9-8-B, A9-8-C, and A9-8-D of the *SCAQMD CEQA Air Quality Handbook.*~~
2. Horsepower ratings for the small compactors and rock trucks are 190 and 398, respectively. The criteria emissions are calculated similarly to operational phase compactors and dirt trucks, respectively. Scrapers are duel engine equipment with horsepower ratings of 200 and 550. PM_{10} emissions are based on equipment manufacturer specifications. ROG and SO_x emissions are calculated using *SCAQMD CEQA Air Quality Handbook*, Table A9-8-A. NO_x and CO are calculated using *Exhaust Emission Factors for Non-Road Engine Modeling – Compression Ignition.*
3. ~~2~~ Based on ~~1995~~1997 emission factors for two medium heavy trucks each driving 5 mph for 10 hours per ~~day with one cold start and one hot soak per truck.~~
4. ~~3~~ Based on ~~1995~~ 1997 emission factors for eight trucks each commuting 40 miles round trip at an average speed of 30 mph ~~with one cold and one hot start and two hot soaks per truck~~.
5. NV = No value is calculated by the EMFAC7G model but value would be inconsequential.
6. ~~4~~ Based on ~~1995~~ 1997 emission factors for 70 workers each commuting 20 miles round trip at an average speed of 30 mph with two cold starts and two hot soaks per vehicle.

~~57.~~ Daily threshold for construction. Note that with the exception of NO_x, all emissions will remain below the SCAQMD quarterly thresholds.

emissions for these vehicles were calculated from the ~~EMFAC7EP~~ 1998 EMFAC7G computer model runs ~~included in the *SCAQMD CEQA Air Quality Handbook*~~. Truck trips will be necessary to deliver construction-related materials. It was assumed that eight trucks will make one round trip of 40 miles. Based on an average speed of 30 mph, ~~one cold and one hot start, and two hot soaks per truck,~~ emissions for these vehicles were calculated from ~~the EMFAC7EP model run included in the *SCAQMD CEQA Air Quality Handbook*~~EMFAC7G.

Equipment use assumes usage during 10-hours per day, with no downtime, and is not averaged over the week to include nonworking days. Actual emissions would be lower if averaging were taken into consideration. Similarly, material deliveries would not be a daily occurrence and worker commutes are based on a separate vehicle for each worker with no ridesharing. This analysis then presents a reasonable worst-case estimate. Actual emissions, both daily and quarterly, are projected to be less than the presented values that are considered "conservative." Projected equipment emissions are included in **Table 4.2-5**.

Based on the projected emissions presented herein, a significant air quality impact is predicted for NO_x. All other gaseous emissions are projected to occur at levels below their respective criteria threshold. No other significant impacts for construction-related exhaust emissions are projected with implementation of the proposed project.

Fugitive Dust Emissions

Fugitive dust is defined as the discharge of particulate matter into the atmosphere from a nonpoint source. Fugitive dust is generated either by a mechanical disturbance to soil (i.e., associated with human activities such as grading operations or agricultural tilling) or by wind-related entrainment of dust particles. Site preparation, clearing, surface grading, excavation, and the use of heavy equipment and trucks on unpaved surfaces have the potential to generate significant quantities of dust during initial site preparation activities. The actual quantity of fugitive dust emissions generated during the construction phase will be governed by the type and amount of work being done, the soil type and moisture, and the prevailing wind conditions.

AP-42: Compilation of Air Pollutant Emission Factors (USEPA,19985) (AP-42) provides emission data for stationary, area, and mobile sources of air pollutants. The document also provides specific methodology for calculating fugitive dust emissions from soil movement. (Many of the emission factors included in the *SCAQMD CEQA Air Quality Handbook* are taken from AP-42.) In accordance with AP-42, when no mitigation measures are implemented, site grading for construction produces approximately 110 pounds of total suspended particulate matter (TSP) per day, per acre graded.[6] This value is based on a medium level of activity, a silt content of about 30 percent, and a semiarid climate. Test data used to derive the specified value are not sufficient to derive the specific dependence of dust emissions on correction parameters and for the purposes of this analysis, none have been applied.

AP-42 estimates the PM_{10} portion of TSP (the portion with an aerodynamic diameter of 10 microns or 0.0004 inch or less) to comprise roughly 45 percent of this TSP or approximately 50 pounds per acre per day. ~~However, local testing by Transit Mixed Concrete at their proposed site located along Soledad Canyon Road~~

[6] *AP-42: Compilation of Air Pollutant Emission Factors*, U.S. Environmental Protection Agency. ~~1985~~1995.

~~(approximately 10 miles north of the project site) has shown that the PM_{10} portion of the TSP comprised only 28.6 percent of all TSP (as opposed to the 45 percent predicted by AP-42). Even this value of 28.6 percent is considered conservative because these samples were obtained from the soil fines (i.e., material that is too small for use in the sand and gravel industry) and would be expected to have even higher PM_{10} levels than the surrounding soil. Based on this information and barring the use of any mitigation, each acre disturbed would be expected to produce about 31.5 pounds of PM_{10} on a daily basis (28.6 percent of 110 pounds/day).~~

Construction work at the proposed landfill footprint would disturb a relatively small area (estimated not to exceed 40 acres at any given time). In accordance with information provided by the project proponent, actual excavation operations would be further restricted to an even smaller area not expected to exceed about 10 acres per day of the 40 acre footprint. ~~By applying the above-referenced factor to the project surface area to be affected, a TSP emissions estimate of 1,100 pounds per day is calculated prior to mitigation. Of this total TSP,~~ and PM_{10} emissions are estimated at ~~315~~ 500 pounds per day prior to mitigation.

~~The USEPA has estimated that the regular watering of a site under construction may reduce fugitive dust emissions by as much as 50 percent;[7] therefore, with watering measures (per SCAQMD Rule 403) project-induced fugitive dust emissions are estimated to be approximately 550 pounds per day for total TSP. With regular watering, the PM_{10} portion of TSP emission is estimated to constitute approximately 158 pounds per day.~~

Erosion of the excavation area will also produce fugitive dust. AP-42 estimates that erosion of exposed areas creates approximately 0.38 ton per acre per year (2 pounds per acre per day) of TSP. (It should be noted that AP-42 does not denote a wind speed used in the derivation of erosion values and actual values could differ from those presented in this analysis.) The PM_{10} portion (i.e., ~~28.6~~ 45 percent of the TSP) is estimated at ~~0.3~~ 0.9 pound per acre per day. As noted above, total disturbed area is estimated at 40 acres at any one time and the daily TSP is calculated at 83 pounds per day, ~~and~~ while the PM_{10} emission is estimated at ~~24~~ 37 pounds per day. ~~Twice daily site watering will reduce this value by an estimated 50 percent.~~

Table 4.2-6 lists the PM_{10} emission sources for initial site construction. The projected PM_{10} emissions from fugitive dust, when added to the projected PM_{10} emissions attributable to vehicle exhausts produce approximately ~~231~~ 546.3 pounds of PM_{10} emissions per day. This value is in excess of the 150-pound-per-day significance criterion recommended by the SCAQMD and a significant impact is projected.

Storage and Dispensation of Fuel

The storage and transfer of diesel fuel for construction equipment are not expected to add substantially to the air pollution emissions. *AP-42: Compilation of Air Pollutant Emission Factors*[8] lists transfer operations for diesel loading from tank trucks as 0.03 pound per 1,000 gallons transferred. Due to the low Reid vapor pressure of diesel, evaporative losses from both onsite and offsite diesel storage are even lower; however, the transfer of this fuel into storage tanks will produce an additional 0.014 pound of ROG per 1,000 gallons.

7/ Ibid.

8/ Ibid.

Based on the *SCAQMD CEQA Air Quality Handbook*[9] and the equipment listing in **Table 4.2-5**, diesel fuel consumption for heavy equipment operating 10 hours per day is ~~calculated~~ estimated at approximately 2,800 gallons per day (gpd). Fuel consumption for the eight material delivery trucks based on 320 miles per day at 5.9miles per gallon (mpg),[10] projects an additional 54 gallons. Based on these values, fuel loss is calculated at 0.1 pound per day and is therefore considered inconsequential.

~~1. No site watering.~~
~~2. Assumes twice Daily site watering as required by SCAQMD Rule 403.~~

Gasoline will also be necessary for fueling worker vehicles. Based on 70 workers each traveling 20 miles per day, 1,400 miles would be traveled on a daily basis. Vapor loss at gasoline stations is presented in AP-42 at 1.8 pounds per 1,000 gallons transferred, including spillage. Moreover, the storage of this fuel in underground tanks at service stations will produce 1.0 pound of ROG for every 1,000 gallons dispensed, and filling these underground tanks will contribute an additional 0.3 pounds per 1,000 gallons. Therefore, every 1,000 gallons of gasoline transferred result in the production of 3.1 pound of ROG. These emission estimates can be expected to be reduced in future years as low-emission gasolines are refined and better methods of vapor recovery are installed at service stations.

Based on an average anticipated fuel consumption of ~~23.5~~ 24.3 mpg (from the ~~1995 EMFAC7EP~~ 1997 BURDEN7G model run) and 1,400 miles traveled on a daily basis, ~~60~~ 57.6 gallons would be dispensed on a daily basis. Vapor loss is then calculated at less than 0.2 pound per day. When combined with the predicted ~~55.5~~ 70.2 pounds per day from exhaust emissions, ROGs from fuel transfer will not exceed the recommended 75-pound-per-day significance threshold.

9/ *SCAQMD CEQA Air Quality Handbook*, op. cit., Tables A9-8-C and A9-8-D.

10/ Ibid., Table A9-5-O.

Summary

Project construction is projected to produce NO_x (~~893.8~~ 1,363.4 lbs/day) and PM_{10} (~~230.8~~ 546.3 lbs/day). These values are in excess of those levels deemed by the SCAQMD as significant. All other emissions are estimated to remain below both daily and quarterly threshold levels.

4.2.8 Air Quality Operational Phase (Long-Term)

After the site is prepared to receive wastes, most air emissions will be produced by hauling refuse to the landfill, erosion of exposed landfill areas, and operating heavy equipment during daily landfilling operations. Emissions, to a lesser extent, will be associated with employee-generated commute trips. Additionally, onsite emissions will be produced by flaring gases produced as a byproduct of refuse decomposition. Minor quantities of emissions would also be produced ~~by the use of electricity for space and water heating and the offsite production of electricity for use onsite.~~ associated with the offsite production of electricity for use onsite. These emissions are, however, minor in comparison to equipment and vehicle emissions and will not add to or change the results of the air quality analysis.

At full operation, the proposed project (combined landfill within both jurisdictions) will receive an anticipated average solid waste intake of approximately 11,000 tons per day (tpd) and a maximum of 12,100. The estimated number of trucks necessary to deliver this intake amount is based on the traffic study submitted by the traffic consultant and is included as Appendix B1 (Traffic Impact Study Report - Sunshine Canyon Landfill, Browning-Ferris Industries, Inc.) within this SEIR. Based on the traffic impact analysis, as many as 220 transfer trucks, 640 curbside collection trucks, and 250 local delivery trucks will transport refuse to the project site on a daily basis. Additionally, up to 87 employees are anticipated to commute to the project site.

Onsite Equipment

During operation, vehicles will be utilized to transport refuse to the landfill. Waste material is deposited within prepared working face areas, compacted, and then covered daily with cover material. A completely covered compacted solid waste unit (or cell) is adjoined to other cells in similar height, making a lift. ~~When landfill capacity of a working area is exhausted, a new area is excavated and lined with an impermeable membrane, and additional cells are formed.~~ Heavy equipment would be used ~~to~~ for ~~excavate~~ cell preparation ~~and prepare new landfill working areas~~, to provide cover material, and to compact refuse on a daily basis. The equipment listings and hours of operation are based on existing requirements at the County Landfill and experience gained when the existing inactive City Landfill was operational. Emissions were calculated using *Exhaust Emission Factors for Non-Road Engine Modeling – Compression - Ignition (EPA Report No. NR-009, February 13, 1998)* or manufacturer specifications where available. Load factors taken from *SCAQMD CEQA Air Quality Handbook* (Table A9-8-D) or manufacturers specifications, where available, were also used in emissions calculations. ~~As previously noted, to present a reasonable worst-case scenario, all equipment is projected to operate 10 hours per day.~~ The equipment utilized and the projected emissions are presented in **Table 4.2-7**.

Mobile Emissions

Employee Commuting

As many as 87 employees (at landfill buildout) would be employed during the long-term operational phase of the proposed project. Based on the home-to-work projections included in the *SCAQMD CEQA Air Quality Handbook* (Table A9-5-D for Los Angeles County), each round trip is projected at a 20-mile distance, for a total of 1,740 miles per day. Emissions for these trips were calculated in accordance with the ~~methodology presented in the *SCAQMD CEQA Air Quality Handbook* (Table A9-5-J-4)~~emission factors projected by the 1998 EMFAC7G model using emission factors projected for the 1998 vehicle fleet and are included in **Table 4.2-8**.

Notes:

1. From **Table 4.2-7** above.
2. Includes 87 employees traveling a total of 1,740 miles at an average speed of 30 mph with two cold starts and two hot soaks per vehicle.

~~3.~~ NV - No value is calculated by the EMFAC7G model but value would be inconsequential

~~34.~~ Includes 220 trucks traveling a total of 11,880 miles at 40 mph ~~with one cold and one hot start and two hot soaks per truck~~.

~~45.~~ Includes 640 trucks traveling a total of 19,200 miles at 25 mph and 3,200 miles at 5 mph ~~with one cold and one hot start and two hot soaks per truck~~.

~~56.~~ Includes 250 light-duty trucks traveling a total of 5,000 miles at 25 mph with one cold and one hot start and two hot soaks per vehicle.

~~67.~~ ~~Based on twice the maximum permitted emissions.~~ Combustion emissions have been revised and are based on permitted emissions for 5 flares, including the existing flares at the City and County landfills, which are already in operation. In 1997, the emission limits for two permitted flares were revised to reflect changes in gas composition for those flares. The emission limits in the original permits were based on the best estimate of gas composition available at the time the permits were issued. Since gas composition changes over time, SCAQMD practice is to periodically revise permitted emission limits to reflect actual conditions.

~~78.~~ NE - No emissions of this type are associated with this operation.

~~89.~~ Daily threshold for operations.

Collection and Transport Trucks

Generally, three types of trucks would be utilized to transport refuse to the project site: transfer trucks that bring in materials from transfer stations, curbside collection trucks that obtain wastes from the local collection routes, and pickup and small stakebed trucks that are primarily used by private contractors to bring in refuse (such as gardening and landscaping green wastes). Each type of vehicle is described below.

Transfer Trucks: Generally, wastes transported in transfer trucks would comprise about ~~46~~ 42 percent of the refuse brought to the project site. These trucks would be received from the BLT Enterprise Central Los Angeles, Santa Monica, Beverly Hills, Culver City, and Falcon (Wilmington) transfer stations. An average round trip is estimated at 54 miles. Based on the traffic study (refer to Appendix B1 of this Draft SEIR), approximately 220 transfer trucks will produce 440 trip ends (TEs). (Note: Travel is based on TEs, so all starts and their attendant emissions are properly accounted.) Based on a one-way travel distance of 27 miles for each TE, approximately 11,880 transfer truck miles will be generated. Because the majority of travel distance for these trucks would be along existing freeway corridors, an average speed of 40 mph is used in accordance with the *SCAQMD CEQA Air Quality Handbook* (Table A9-5-F). Emissions are calculated in accordance with ~~the *SCAQMD CEQA Air Quality Handbook* (Table A9-5-K-4)~~ emission factors projected by the 1998 EMFAC7G model and included in **Table 4.2-8**.

Curbside Collection Trucks: The proposed project would also have collection vehicles transporting refuse to the project site. It is anticipated that curbside collection vehicles from the communities of Granada Hills, Chatsworth, West San Fernando, Encino, and numerous west Los Angeles cities (e.g., Santa Monica, Culver City, Beverly Hills, and Inglewood) would transport refuse to the site. These vehicles would comprise about ~~52~~ 56 percent of the waste brought to the project site, and as many as 640 trucks would generate about 1,280 daily TEs.

During curbside collection, these trucks are projected to average about 5 mph and travel approximately 5 miles before reaching load capacity. The trucks would transport refuse to the landfill using an average speed of 25 mph. (Note: The reduced average speed for collection trucks, as opposed to transfer trucks, is due to their project proximity and reduced freeway use.) Representative average speeds for all vehicles in Los Angeles County are presented in the *SCAQMD CEQA Air Quality Handbook* (Table A9-5-F).

Because the geographic locations of curbside collection will vary, an average distance of about 15 miles to the landfill (30 miles round trip) is assumed in this analysis. This value is based on approximately half of the transfer truck distance. Based on this assumption and the above, each collection truck will travel 30 miles at 25 mph and 5 miles at 5 mph. The resulting emissions have been calculated in accordance with ~~the methodology presented in the *SCAQMD CEQA Air Quality Handbook* (Table A9-5-K-4)~~ emission factors projected by the 1998 EMFAC7G model.

Local Deliveries: Local deliveries include the use of small pickups (0.75- to 1.5-ton load capacity) and stakebed trucks. Generally, these vehicles would collect and transport landscaping material, green wastes, and wood wastes. These deliveries comprise less than 2 percent of the total vehicle trips to the project site and, as a result, would represent a very small percentage of the total volume of solid waste transported to the project site on a daily basis. An estimated 250 local delivery vehicles will also produce 500 daily TEs. An average round trip distance of 20 miles, assuming an average speed of 25 mph, is used in the emissions calculation. Emissions have been calculated in accordance with ~~the methodology presented in the *SCAQMD CEQA Air Quality Handbook* (Table A9-5-J-4)~~ emission factors projected by the 1998 EMFAC7G model.

Other Emissions

Various other emission sources are also associated with operation of the landfill facility. Electricity is used for water heating and is anticipated to be used to operate various types of onsite equipment and lighting and will ~~produce~~ result in offsite emissions at the local power generating station. In accordance with *SCAQMD CEQA Air Quality Handbook* each megawatt of electricity consumed produces only 1.64 pounds of all pollutants combined. Therefore these emissions, would be minimal and are not considered significant due to existing and projected ~~sufficient~~ capacity, which is sufficient and available. Based on the conservative method utilized in the derivation of heavy equipment and vehicle emissions, these electrical emission sources will not produce a change in the outcome of this impact analysis.

Other emission sources include the development and use of the flaring stations and the storage and transfer of nonrenewable fuel for project-related vehicles, ~~that~~ which will result in VOC emissions from the evaporation of fuel during its storage and transfer. These potential sources are discussed below.

Combustion of Landfill Gas Emissions

Rule 1150.1 of the SCAQMD requires the collection of gas generated by landfills and the destruction of the gas collected from the landfill site. In order to comply with this rule, collected LFG would be burned in high-efficiency flares, each with a total volume disposal capacity of approximately 6 million standard cubic feet per day (scf/day) or 4,167 standard cubic feet per minute (scf/min). While the *FEIR Sunshine Canyon Landfill Extension* proposed a total of eight flaring stations within Sunshine Canyon, revisions in LFG generation calculations as well as experience gained in the generation rates associated with the existing inactive City Landfill have shown that only two additional flare stations will be required for the proposed City/County Landfill project~~, in addition to the two landfill gas flares already permitted for the County Landfill~~ for a total of five flares. An existing flare station is located in the southwest perimeter area of ~~Sunshine Canyon~~ in the existing inactive City Landfill and two additional flares are proposed in the City's jurisdiction. (Refer to **Figure 2.5-1** of the Draft SEIR.) Currently, and within the County, two flares are permitted but only one flare station has been constructed. This flare ~~will become~~ is now operational. The existing flare station in the City is now operating at approximately 50 percent of its permitted capacity and would be utilized for the proposed project until sufficient LFG is generated to warrant development of an additional flare station(s) in the City portion of Sunshine Canyon.

A typical LFG flaring station encompasses approximately ½ acre of land and is well secured with perimeter fencing ~~and locked for safety purposes~~. The flare itself includes several components that consist of a condensate knockout drum, a condensate pump, three blowers, particulate filter, two flame arresters, one flare, an LFG flow meter, and an LFG emergency shutoff valve. The proposed LFG station would be designed similar to the constructed County Landfill flare station, which includes a flare stack approximately 50 feet high and ~~13~~ 12.5 feet in diameter.

The proposed flare stations located in the City would be considered sources of new emissions, subject to SCAQMD's Permit to Construct and Permit to Operate rules and regulations. Compliance with these permits would require performance testing of the landfill gas flaring system prior to 60 days of achieving normal operation and annually in accordance with SCAQMD testing procedures. Performance tests are conducted at the maximum flow rates available and do not exceed the flow rate allowed by the Permit to Construct. Tests of the inlet landfill gas flare and the flare exhaust are conducted for methane, total non-methane organics, non-methane organics (i.e., speciated and quantified), oxides of nitrogen, carbon monoxide, total

particulate, hydrogen sulfide, total sulfur compounds, hydrogen chloride, carbon dioxide, oxygen, nitrogen, moisture content, BTU content, and flow rate.

Generally, emissions for gas combustion are calculated in accordance with emission factors utilized by the SCAQMD for natural gas flares and the amount of emissions expected from flaring activities at the facility. The flare emissions would be controlled to meet the SCAQMD's best available control technology (BACT).

As stated previously, two new flare stations are currently proposed in the City jurisdiction, in addition to two permitted flare stations (one of which is constructed and in operation) located within the County jurisdiction, and ~~existing~~ the currently operating flare station within the City. A total of five flare stations would be located within Sunshine Canyon. ~~Permitted for combustion~~ The maximum emissions allowed for the three permitted flares are presented in **Table 4.2-9**. One of the existing flares was recently repermitted with new emissions/ limitations, while the other two permitted flares (one of which is currently operational) are permitted at older limitations. It is projected that all five flares will be subject to the revised limitations of the re-permitted unit and all these revised emissions factors have been used for all five flares in the included analysis.

Table 4.2-9 (Revised)
PERMITTED MAXIMUM DAILY EMISSIONS FROM EXISTING FLARING ACTIVITIES[1]

Pollutant	Permitted Emissions from Landfill Gas Flaring (lb/day)
CO	~~720.0~~ 1,544
NO_x	~~144.7~~ 462.0
NMHC[2]	~~15.2~~ 55.0
SO_x	~~32.4~~ 169.0
PM_{10}	~~18.0~~ 77.0

Source: Ultrasystems Environmental Incorporated
Notes:
1. Based on SCAQMD permits for three existing flares
2. Nonmethane hydrocarbons (NMHC). These emissions are also considered as ROG.

~~Note that the existing flare station (within the City) is currently operating at about 50 percent of its 105 million British thermal units per hour capacity; existing emissions are reduced accordingly. For CEQA purposes, the volume of emissions associated with the permitted activities has been doubled to include both existing emissions, and the proposed City/County Landfill Project at buildout or 11,000 tpd of accepted waste.~~

Fuel Storage and Dispensation

Volatile organic emissions are associated with the storage and transfer of fuel to project-generated vehicles. The 220 transfer trucks and 640 refuse collection trucks are anticipated to travel approximately 34,280 miles per day. Based on an average fuel consumption of 5.9 mpg predicted ~~in the *SCAQMD CEQA Air Quality Handbook* (Table A9-5-O)~~ by the BURDEN7G model, an estimated 5,810 gallons of fuel may be used daily. All of these vehicles are ~~all~~ assumed to use diesel fuel.

Diesel fuel will also be utilized by onsite equipment and machinery. When the existing inactive landfill was operational during peak capacity (i.e., 6,000 tpd), onsite equipment and machinery utilized approximately 450 ~~gpd~~ gallons per day (gpd) of diesel fuel. For the proposed project, this value was doubled and daily diesel consumption for heavy equipment is estimated at 900 ~~gallons per day~~ gpd.

Based on the consumption quantity of 900 gpd utilized for onsite operations, plus fuel usage for vehicles transporting refuse to the landfill site, the total diesel consumption is projected to be approximately 6,700 gpd for the proposed project. Based on AP-42 requirements, approximately 0.03 pound of vapor (ROG) is released per every 1,000 gallons transferred from storage into vehicles. Storage of this fuel source would contribute an additional 0.014 pound per 1,000 gallons. Based on these estimates, approximately 0.3 pound of vapor emissions is anticipated to occur at the project site on a daily basis.

Gasoline will be utilized by landfill employees who would be commuting to the site and service vehicles and light-duty vehicles that would transport wastes to the site. As discussed above, employees are anticipated to generate approximately 1,740 commuter miles per day. Onsite service vehicle use is assumed to be minimal and is therefore conservatively projected to generate 100 miles per day. Light-duty trucks are projected to travel approximately 5,000 miles per day. In accordance with the ~~*SCAQMD CEQA Air Quality Handbook* (Table A9-5-O)~~ BURDEN7G model, fuel economy for employee commute vehicles is projected to be ~~25~~25.2 mpg; therefore, the daily fuel consumption for all employees is estimated to be approximately ~~70~~69 gpd. The fuel economy for both onsite service vehicles and light-duty trucks is projected to be ~~20~~22.4 mpg; therefore, these vehicles will consume approximately ~~255~~228gpd. Based on a value of 3.1 pounds of VOC per 1,000 gallons consumed, vapor loss due to gasoline storage and distribution is calculated at ~~1.00~~.9 pound per day.

Fugitive Dust

Fugitive dust is produced by daily site operations, including landfilling operations, the ~~excavation~~ preparation of ~~new~~ landfilling areas, procurement of cover material, wind action on material that has been stockpiled during the initial construction and on disturbed areas, and truck travel on both the paved access roadway and the unpaved haul route surface to the active working face. Following initial site preparation, normal operations and disturbed areas would be confined to approximately ~~40~~20 acres. Heavy equipment would be utilized ~~to~~ for landfill ~~excavate~~ cell development ~~and prepare new landfill cells~~, as needed, procurement of cover materials, and refuse compaction ~~refuse~~ on a daily basis. Of the ~~40~~20-acre area, up to 10 acres would be used for active landfilling operations, including the active working face and truck turnaround area. ~~It is anticipated that an additional 10 acres would be used for the procurement of cover materials. The entire 40 acres would be subject to erosion and potential fugitive dust emissions.~~

Active Working Face Area and Truck Turnaround. It is anticipated that an active ~~working face~~ area of up to 10 acres would be disturbed at any one time. The actual area for landfilling is expected ~~at~~ to be approximately ~~25,000 sq. ft. or about 0.6~~ 1.0 acre ~~per day~~. This area would receive the solid wastes and be

compacted and covered with soil material on a daily basis. The remaining area is the waste-bearing truck turnaround. The turnaround area consists of densely compacted soil similar to an unpaved road. ~~Based on a value of 31.5 pounds of PM_{10} emissions per acre per day, approximately pounds of PM_{10} emissions would be produced during daily cover and compaction operations. Dust would also be generated during the disposal and movement of refuse at the working face area. Unloading refuse would not create substantial quantities of dust emissions.~~ Fugitive PM_{10} emission sources at the active working face area and truck turnaround consist of heavy vehicle operations, unloading of solid waste, dumping of daily cover, wind erosion of the active working face, and truck travel in the turnaround area. Fugitive PM_{10} emissions from heavy equipment operations are calculated according to the *SCAQMD CEQA Air Quality Handbook* (Table A9-9-F) and are provided in **Table 4.2-10**. Fugitive PM_{10} emissions calculations from material handling activities are estimated according to *SCAQMD CEQA Air Quality Handbook* (Tables A9-9 and A9-9-G) and are shown in **Table 4.2-11**. Fugitive PM_{10} emissions from wind erosion of exposed surfaces are calculated according to AP-42 (Table 11.9-4) and are shown in **Table 4.2-12**. Fugitive PM_{10} emissions calculations from truck travel on the truck turnaround area are estimated according to *AP-42* (Chapter 13.2.2) and are shown in **Table 4.2-13**.

Landfill Area ~~Excavation~~ Preparation. When additional landfill areas are ~~excavated~~ prepared, an area of up to 10 acres would be disturbed. Ongoing ~~excavation~~ preparation activities are necessary to keep pace with the projected landfilling operations. ~~As discussed above, the area of active landfilling is anticipated to encompass approximately 0.6 acre per day.~~ Fugitive PM_{10} emission sources during landfill preparation include heavy equipment operations and wind erosion of the area.

~~The area for landfilling operations includes both a deck area for vehicle maneuvering and a trench area estimated at a depth of approximately 20 feet. Access to the trench area will be sloped. If excavation would require that landfill be ramped at a 2:1 (horizontal to vertical) slope, the area for excavation is estimated at roughly twice the working face area or about 1.2 acres per day. Based on a value of 31.5 pounds of PM_{10} emissions per acre per day, about 38 pounds of PM_{10} would be generated from landfill excavation.~~

Cover Procurement. ~~Cover procurement would occur in an area of up to 10 acres. Assuming that 1 foot of cover material is required for the daily cover at the working face and that the material is procured to a depth of 2 feet, one-quarter acre would be excavated on a daily basis. It is estimated that fugitive dust emissions from the procurement of cover material would be approximately pounds per day.~~ Daily cover is applied over compacted waste on the active working face. The amount of cover required on a daily basis was calculated assuming that 1 cubic yard of cover is needed for every 10 tons of waste dumped. Cover material consists of clay at 1.2 tons per cubic yard. Therefore, approximately 1,450 tons of cover material is procured daily from one of two anticipated stockpile areas. Fugitive PM_{10} emission sources during cover procurement include heavy equipment operations, wind erosion of cover stockpile areas, and excavation of the cover stockpile. Fugitive PM_{10} emissions calculations from stockpile erosion according to *SCAQMD CEQA Air Quality Handbook* (Tables A9-9-E) are shown in **Table 4.2-12**.

Surface Erosion. As mentioned above, ~~daily operations would typically be restricted to small areas of land (approximately 10 acres although as much as 40 acres could be excavated at any one time). Based on a value of 0.3 pound of PM_{10} per acre per day and 40 acres, approximately 12 pounds of PM_{10} would be generated as a result of potential surface erosion.~~ surface erosion occurs at the active working face and during landfill preparation. Calculation of fugitive PM_{10} emissions from surface erosion is provided in **Table 4.2-12**.

Table 4.2-10
FUGITIVE UNCONTROLLED PM_{10} EMISSIONS FROM HEAVY EQUIPMENT OPERATIONS

Emission Source: Heavy Equipment Operations 1/1

Introduction: Heavy equipment operations produce fugitive PM_{10} dust during bulldozing, grading, and compacting activities. Equipment is used to landfill waste at the active working face, provide cover at the active working face, prepare landfill areas for receiving waste, and maintenance in other landfill areas.

Parameters:

TOTAL					***Uncontrolled PM_{10} Emissions - pounds/day***		***277.4***

Source: Browning-Ferris Industries

Note:
* This round trip distance reflects the worst-case daily PM_{10} emissions. For modeling purposes, the highest PM_{10} contributing sources were placed nearest to potential receptors resulting in a round trip distance of 0.216 miles.

Conclusion: The uncontrolled PM_{10} emissions from paved road travel that could result in the worst-case daily total PM_{10} emissions are 277.4 pounds/day.

Stockpile Erosion. During initial site construction, soil material will be stockpiled and stored onsite for subsequent use as daily cover material. Estimates for soil stockpiling indicated that as much as 500,000 cubic yards of soil may be stockpiled at any given time. This material would be utilized and depleted over time~~; it~~ and would not be replenished. ~~Subsequent cover material would be obtained by daily procurement (discussed above), and~~ Therefore, the fugitive dust emissions associated with the stockpile would eventually be alleviated. However, while the soil remains onsite, the stockpile would be subject to erosion and potential fugitive dust emissions. At a height of 10 feet, the two anticipated stockpile areas would together require a land area of approximately 30 acres. Calculation of fugitive PM_{10} emissions from stockpile erosion is provided in **Table 4.2-12**.

~~Included within AP-42 (Table 8.19.1-1) is a listing of PM_{10} emissions for stockpiles at sand and gravel processing plants. Based on this type of listing it is anticipated that approximately 1.7 pounds per acre per day for inactive stockpiles and 6.3 pounds per acre per day for active stockpiles would be generated. It is assumed that 1 acre of stockpile material would be active and that 55.6 pounds of PM_{10} would be generated on a daily basis. By adjusting this value to reflect the reduced onsite PM_{10} content, approximately 35 pounds of PM_{10} emissions would be released.~~

~~Vehicular~~**Truck Travel on Paved Surfaces.** Because dust generally settles on horizontal surfaces, onsite ~~vehicular~~truck travel over paved surfaces would also produce fugitive dust emissions. ~~In accordance with the AP-42, the equation used in this analysis includes the following calculation:~~

~~$E = k(3.5)(sL/0.35)^{0.3}$~~

~~where E = emission factor (in pounds per vehicle mile traveled [VMT])~~
~~k = particle size multiplier (dimensionless)~~
~~sL = road surface silt loading (in ounces per square yard~~

~~For transfer trucks traveling along the access roadway, the calculated emission factor would use the following values:~~

~~k = 0.22 (for PM-10 particulates)~~
~~sL = 3.2 ounces per square yard (extrapolated from 100 grams per square meter in Table A9-9-C-1 of the SCAQMD CEQA Air Quality Handbook for industrial sites in operation)~~

~~Based on these calculations, approximately 1.5 pounds per mile of PM_{10} emissions would be generated by the truck traffic using the paved portion of the access road.~~ The paved portion of the access roadway leads from the landfill site entrance through the scale house area to the active working face areas, and is approximately 1 mile in each direction. There are curbs and gutters the entire length of the paved portion of the access road. ~~Approximately 1,110 trucks (i.e., 220 transfer, 640 collection, and 250 local delivery) would travel nearly 2,200 miles over paved surface areas to the working face and potentially generate 3,330 pounds of PM_{10} emissions per day.~~ Fugitive PM_{10} emissions from truck travel on paved surfaces are estimated according to *AP-42 Chapter 13.2.1* and are shown in **Table 4.2-14**.

Truck Travel on Unpaved Surfaces. Dust is also associated with ~~vehicular~~truck travel over unpaved or hard-packed surfaces ~~such as the haul road~~. Unpaved surfaces at Sunshine Canyon Landfill consist of the crushed stone covered portion of the access road, the truck turnaround area, and the stockpile road used for dirt truck travel between the cover stockpile and the active working face. ~~In accordance with~~ Fugitive PM_{10}

emissions from truck travel on unpaved surfaces are calculated according to *AP-42 Chapter 13.2.2* and are shown in **Table 4.2-13**. ~~, the equation used in this calculation is~~

~~$E = k(5.9)(s/12)(S/30)(W/3)^{0.7}(w/4)^{0.5}(365-p/365)$~~

~~where E = emission factor (in pounds per VMT)~~
~~k = particle size multiplier (dimensionless)~~
~~s = surface material silt content (percent)~~
~~S = mean vehicle speed (mph)~~
~~W = average vehicle weight (tons)~~
~~w = mean number of wheels~~
~~p = number of days of precipitation per year~~

~~For transfer trucks traveling along the unpaved surfaces, the calculated emission factor would use the following values:~~

~~k = 0.36 (for PM-10 particulates)~~
~~s = 4.8 percent (mean value for sand and gravel processing, from AP-42)~~
~~S = 10 mph~~
~~W = 16 tons (average weight of full transfer trucks coming in [19 tons] and empty trucks leaving [13 tons])3~~
~~w = 18 wheels per truck~~
~~p = 40 days (from AP-42 rain areal distribution map)~~

~~Based on this calculation, approximately 1.7 (per mile) of PM_{10} emissions would be generated from the 220 transfer trucks traveling along unpaved surfaces. Emissions for curbside collection trucks are estimated by substituting an average vehicle weight of 10 tons and 10 wheels into the equation, and each of the 640 trucks are projected to generate about 0.9 pound of PM_{10} emissions per mile traveled. Additionally, the vehicle weight of each of the 250 local delivery trucks is assumed to average 2.5 tons. Each vehicle includes four wheels and would produce 0.2 pound of PM_{10} emissions per mile traveled. Based on a roundtrip distance of 800 feet, these trucks are projected to generate approximately 152 pounds of PM_{10} emissions per day. Emissions for each truck type are summarized in **Table 4.2-10**.~~

~~Source: Ultrasystems Environmental Incorporated~~
~~Note: Based on a round-trip distance of 800 feet.~~

~~**Total Dust Generation.** When the above emission estimates are added (in the absence of mitigation), a total of 3,594 pounds of PM_{10} emissions could be generated by site operations on a daily basis. **Table 4.2-1**~~

Carbon Monoxide Micro-Scale Analysis

Emissions of CO from motor vehicles can cause localized problems in areas where high CO concentrations already exist. The *SCAQMD CEQA Air Quality Handbook* requires additional analysis of CO emissions for the following projects: (1) projects that may subject sensitive receptors to CO concentrations in excess of State and federal standards, (2) projects that may potentially impact the level of service of a roadway, and (3) projects that would have a significant impact on air quality. Typically, CO emissions from a project are modeled, and the predicted concentration is added to the ambient CO concentration level to obtain the total project impact. The 1- and 8-hour CO standards constitute the threshold values above which CO emissions would be considered significant. The locations where the CO thresholds are exceeded are called "hot spots." If CO hot spots are located at sensitive receptor locations, concentrations of CO at the sensitive receptors must be compared against recognized thresholds.

Roadway impacts are estimated using dispersion models that are based on continuous line source emissions. In accordance with SCAQMD recommendations and methodology, dispersion modeling for the project using the CALINE4 computer model was performed. Modeling was utilized to determine the potential for CO hot spots at local intersections with sensitive receptors ~~for future 1997 and 1998 traffic emissions data~~. The analysis was based on existing conditions, plus cumulative project and project-generated traffic. Therefore, a worst-case scenario model run was performed. The analysis considers a composite vehicle mix, including 87.64 percent passenger cars, 11.66 percent trucks, 0.68 percent motorcycles, and 0.02 percent buses.

Although approximately 73 percent of traffic associated with the project is derived from heavy trucks, in this analysis, the trucks associated with the project were converted into passenger car equivalents (PCEs) and essentially "double counted" for curbside collection trucks and "triple counted" for transfer trucks. Conversion factors yield a composite 2.25 PCE per truck. This value is reasonable since, at 20 mph, a truck

would produce approximately 2.5 times the volume of CO as a passenger car. In the composite analysis, 11.66 percent of the project-related vehicles are trucks. The composite vehicle mix was prepared in accordance with the *SCAQMD CEQA Air Quality Handbook* (Table A9-5-P-1) for both running and idle CO emissions.

As a worst-case scenario, the evening peak hour was modeled (based on information presented in the traffic study) because these hours generally produce the greatest traffic volumes. In accordance with the *SCAQMD CEQA Air Quality Handbook* (Table A9-5-F), the average anticipated speed during the PM peak hour for Los Angeles County is projected at 22.0-mph for the year 1998. Because the model used in the *SCAQMD CEQA Air Quality Handbook* predicts emissions in 5-mph increments, an average speed of 20 mph was used to present a reasonable worst-case scenario. Results of this modeling are presented in **Table 4.2-~~12~~5**. In accordance with the model, no exceedance of either the State or federal CO standards are projected, and no significant impacts are predicted as a result of project implementation. Model runs of this analysis are presented in Appendix B8, within ~~this~~ the Draft SEIR.

4.2.9 Health Risk Analysis

~~In addition to the generation of potential criteria pollutants, thermal destruction of the LFG through the proposed flare system(s) has the potential to release carcinogenic or toxic air contaminants (TACs) that may individually or cumulatively exceed the maximum individual cancer risk rate of one in 1 million. To determine the potential for such an impact, a health risk screening assessment was performed by air quality consultants and is included in Appendix B6 of this Draft SEIR.~~

~~Two potential types of impacts were considered in the dispersion calculations and include (1) a screening level health risk assessment for any excess cancer risk from that fraction of TACs not destroyed in the LFG combustion process relative to SCAQMD Rule 1401, and (2) a screening level ambient air quality analysis for criteria air pollutants (those with clean air standards) from the combustion byproducts from the LFG flare system. In accordance with SCAQMD Rule 1303 (New Source Review), the USEPA SCREEN2 dispersion model was utilized to determine the maximum pollutant concentration at downwind receptor locations (offsite impacts). This model generates peak-hour concentrations based on point or area geometry, plume buoyancy, terrain, meteorology, and release rates. For daily and annual averages, conservative (over-predictive) multiplication factors were utilized to convert the predicted peak-hour concentrations to extended exposure periods.~~

~~In accordance with SCAQMD guidelines and several meetings with SCAQMD staff, modeling protocols were specified for the proposed project within the jurisdiction of the City. This analysis was conducted for the nine carcinogenic TACs (i.e., benzene, carbon tetrachloride, chloroform, dichlorobenzene, ethylene dichloride, methylene chloride, perchloroethylene, trichloroethylene, and vinyl chloride) and five noncarcinogenic constituents (i.e., benzyl chloride, chlorobenzene, methyl chloroform, toluene, and xylene) that have the potential to contribute to acute (short-term) or chronic (long-term) health impacts. These substances are listed in **Table 4.2-13** and define potential health impacts. Modeling was performed using in-flare exhaust concentrations derived from a source test of the existing landfill flare station (August 1995). The measured values were augmented to a combustion rate of 4,400 cubic feet per minute, which is the maximum flow rate permitted by the SCAQMD.~~

Table 4.2-~~12~~ 15 (Revised)
CO HOT SPOT ANALYSIS FOR LOCAL RECEPTORS

Intersection	1997 1-Hour Ambient CO Concentration (ppm)[1]	Total 1997 1-Hour CO Concentration (ppm)[2]	Exceeds State Standard[3]	1997 8-Hour Ambient CO Concentration (ppm)[4]	Total 1997 8-Hour CO Concentration (ppm)[5]	Exceeds State Standard[6]

Source: Linscott, Law & Greenspan, Engineers and Ultrasystems Environmental Incorporated

Notes:
1. Per Table 5-2 of the *SCAQMD CEQA Air Quality Handbook.*
2. Worst-case corner as measured at a distance of 50 feet from the edge of the near lane.
3. Based on a State standard of 20 ppm.
4. Per Table 5-3 of the *SCAQMD CEQA Air Quality Handbook.*
5. Based on a persistence factor of 0.6 for areas in attainment of the CO standard.
6. Based on a State standard of 9.1 ppm.

~~It should be noted that the SCREEN 2 model is not designed for a complex terrain such as Sunshine Canyon. Mountainous terrain and foliage have the potential to impinge on the flare's plume, create local mixing, and limit downwind concentrations. The model is not able to account for these effects. However, the model can be used to present a "worst-case scenario." To utilize this model, the project area was modeled as if it were flat with zero plumes rising from the flare station. This allowed for the greatest prediction of excess health risk. In other words, the model will "over predict" rather than "under predict" excess health risks.~~

~~Findings of the analysis indicated that the cumulative maximum individual cancer risk is 0.0182 in 1 million, as compared to a significant threshold of one in 1 million. The cancer risk to the maximum exposed individual is substantially below any level of concern based on conservative assumptions. With less restrictive input assumptions, the cancer risk would have been even lower.~~

~~Along with the potential carcinogenic, chronic, and acute health risks, LFG emissions have the potential to create pollutant concentrations in excess of SCAQMD Rule 1303 threshold criteria. Results of the SCREEN 2 impact assessment compared to the SCAQMD *de minimis* thresholds in Rule 1303 resulted in all pollutants having less than significant impacts when conservative (i.e., over predictive) assumptions were utilized. Less conservative assumptions would have created an even greater margin of safety between ambient impacts and significant criteria thresholds.~~

~~In addition to individual cancer risk impacts, the TACs listed in **Table 4.2-13** were modeled for potential chronic health risks using the hazard index recommended by the California Air Pollution Control Officers Association (CAPCOA). The chronic health impact predicted in the health risk assessment is 0.0000409, or under conservative impact assumptions, the level is less than 0.001 percent of the significant threshold of a hazard index significance level of 0.5 recommended by CAPCOA. Similarly, acute health risk impacts are predicted at 0.0000292, with a hazard index of 0.5 being a potentially significant impact. Based on the results of the SCREEN 2 dispersion modeling identified in the risk assessment, both chronic and acute health risks (using the CAPCOA hazard index) are clearly considered less than significant. Results of flaring the LFG, both in terms of TACs and criteria air pollutants, will also have a less than significant impact.~~

~~In addition to criteria for chronic and acute health risks, emissions produced by LFG flaring could potentially exceed CAA standards. Criteria pollutants, including CO, NO_2, PM_{10}, and SO_2, were assessed for potential contribution at the maximum exposed individual. These values were compared to the Rule 1303 threshold levels to determine a level of significance. All emissions generated are at less than allowable levels, and no significant impacts are projected as a result of LFG flaring. Results of this analysis are presented in Appendix B7 of this Draft SEIR.~~

A health risk assessment (HRA) was conducted to evaluate the carcinogenic and noncarcinogenic risks associated with toxic air contaminant (TAC) emissions from the Sunshine Canyon Landfill. The risks due to the cumulative emissions from both the "City" and "County" portions of the project were calculated.

The approaches and methodologies used in this risk assessment are from the document entitled, "Air Toxics Hot Spots Program, Revised 1992 - Risk Assessment Guidelines", prepared by the AB 2588 Risk Assessment Committee of the California Air Pollution Control Officers Association (CAPCOA), October 1993. Input assumptions were coordinated with the staff of the South Coast Air Quality Management District (SCAQMD). The CAPCOA procedures for risk assessments from airborne contaminants is the methodology recommended for use by the SCAQMD. All emission estimates used to calculate risk values were from monthly analyses of landfill gas and from periodic emission source tests of the existing flare conducted pursuant to SCAQMD requirements.

Per the requirements of the SCAQMD, the HRA addressed a total of 18 substances on the SCAQMD Rules 1150.1 and/or 1401 lists for the landfill risk evaluation. The substances are listed in **Table 4.2-16**. Of the 18 substances, 10 are considered carcinogenic and were evaluated as part of the cancer risk evaluation. The noncancer health effects evaluation addressed 17 of the 18 substances for chronic impacts, and 7 of the 18 substances for acute impacts.

Note: * Not listed in CAPCOA HRA guidelines as having carcinogenic or noncarcinogenic health risks.

The lifetime carcinogenic risk was estimated for an individual assumed to reside continuously for 70 years at the off-site location of maximum ground-level concentration for the maximum exposed individual (MEI). The chronic and acute health risks were calculated in terms of a "hazard index". This index is calculated by

dividing the predicted maximum short- (acute) and long-term (chronic) pollutant exposures by an established safe exposure level called the Reference Exposure Level (REL; CAPCOA, 1993).

Modeling Methodology

Health risks associated with landfill proximity were assumed to derive from landfill gas (LFG) emissions. These emissions result from that fraction of the LFG not collected by the collection/ disposal system, called "fugitive" emissions, plus the small fraction of TACs emitted by the flares. These emissions were used in a computerized dispersion model (ISCST3, Version 97363) to predict the maximum hourly, daily and annual LFG concentrations at the landfill boundary and at the nearest residences and school locations.

Modeling protocols were coordinated with the SCAQMD staff. Meteorological data from the SCAQMD "Newhall" monitoring station was used as the closest and most representative data resource.

A grid of 90 points along the landfill perimeter and 12 Granada Hills residences plus one school (e.g., Van Gogh Street Elementary School) was used to determine off-site exposure to combined flare and fugitive LFG emissions. The off-site grid is shown in Appendix D3, Revisions to Draft SEIR Appendix B6, Low-Level Health Risk Assessment, **Figure 1**, in this document. The residential receptor with the calculated highest concentration of contaminants was analyzed for health risk potential as a worst-case human exposure location. The maximum exposure was determined to be at the residential receptor designated as #50 in **Figure 1**, which is the residence in the community of Granada Hills that would be the most impacted by landfill emissions.

The composition of the gas flare emissions was determined from monthly analysis data of the "raw" LFG entering the existing flare on the "City" portion of the landfill. The maximum number of flares is five flares burning slightly over 20,000 CFM. Over the 70-year risk assessment time frame, the average annual volume generation for LFG emissions will be approximately 60 percent of the highest year based on peak volumes determined from gas generation predictive models or 12,260 CFM. The input parameters for each of the five (5) flares needed during maximum LFG generations were as follows:

Stack Height	=	15.3 meters
Stack Temperature	=	1180° K
Exit Velocity	=	10 m/sec
Stack Diameter	=	3.8 meters
Max. LFG Rate	=	4167 CFM/flare
70-Year Average LFG Rate	=	2452 CFM/flare

The concentration of TACs in LFG was determined from an average of six monthly LFG composition tests conducted from July-December, 1997 by AtmAA, Inc. Flares were assumed to destroy 98 percent of TACs during combustion. Actual measurements of organic gas destruction efficiencies over the last five years have shown better than a 99 percent destruction efficiency. Use of the 98 percent destruction efficiency assumption over estimates the actual flare impact two-fold compared to actual observed flare behavior.

A total of ten percent of all LFG generated was assumed to escape collection.[11] The fugitive LFG was assumed to be uniformly emitted over approximately 2,000,000 square meters (500+ acres) of landfill surface (both City and County areas). The ISCST3 model was run for a unit emission rate (1 g/sec for each flare, 1 $\mu g/m^2$/sec for fugitive area sources). The exposure for each TAC was calculated based upon the ratio of the estimated emission rate to the reference (unit) rate.

Model Results

Output from the ISCST3 model is attached. The maximum exposed individual (MEI) is the residence in the community of Granada Hills located closest to the landfill, and is labeled as #50 in Appendix D3, Revisions to Draft SEIR, Appendix B6, Low-Level Health Risk Assessment, **Figure 1** in this document. The concentration of TACs within the LFG and the maximum estimated ambient concentrations at the MEI are shown in Appendix D3, **Table 2**. These predicted concentrations were combined with the appropriate exposure parameters and toxicity data to complete the HRA.

Individual Cancer Risk

Excess cancer risk is calculated by assuming the MEI remains outdoors for 24 hours per day for 365 days per year, for 70 years. While a 70 year exposure assumption is the standard assumption for a CAPCOA health risk assessment, the excessively conservative (over-predictive) nature of this assumption needs to be recognized.

Appendix D3, Revisions to Draft SEIR, Appendix B6, Low-Level Health Risk Assessment, **Table 3** in this document combines the predicted chronic exposure for 70 years of LFG emissions (1998 - 2068) to predict the excess individual cancer risk at the #50 receptor. The worst-case MEI exposure is 0.96 in one million. A risk of one in a million is considered less than significant. Risks up to ten in a million are considered acceptable if toxics best available control technology (T-BACT) is used to reduce emissions. Flares are considered T-BACT for landfills. The excess cancer risk is thus below the "de minimus" insignificance threshold, and far below the allowable exposure for a T-BACT equipped source. All other receptors have lower exposures than the MEI.

No amount of excess cancer risk is "acceptable" for the person contracting the disease. However, people accrue far higher risks from common daily activities, in comparison to a less than one in a million risk due to landfill proximity. Appendix D3, **Table 4** shows the mortality risk from accidents and disasters for the average American. Appendix D3, **Table 5** puts the maximum cancer risk in perspective compared to some other risk factors.

Chronic Health Risk

The TACs considered in this assessment are known to potentially affect seven organs/systems in the human body as shown in Appendix D3, Revisions to Draft SEIR, Appendix B6, Low-Level Health Risk Assessment, **Table 6** in this document. Non-cancer effects are calculated through a ratio of the TAC exposure to a published level determined to have no observable health effect (the REL). The sum of all the individual ratios for every identified pollutant emitted by a source is called the health hazard index (HHI). An HHI of 0.5 is considered a potentially significant impact that would require additional analysis. If the HHI is less

[11]/ The SCAQMD recommends using a ten percent escape rate for HRA modeling.

than 0.5 (below 50 percent of the "safe" exposure level), no additional analysis is necessary. Appendix D3, **Table 7** calculates the HHI for any individual target receptor location in the human body. All are well below the significance level of 0.5.

Appendix D3, **Table 8** compares and combines the HHI for all organs/systems. Although HHI's are not strictly additive, the combined threat to all organs/systems of 0.0113 is well below the 0.5 HHI significance threshold. Accordingly, chronic non-cancer health effects from landfill proximity are less than significant.

Acute Health Hazard

The acute health hazard was similarly calculated as the chronic HHI. Appendix D3, Revisions to Draft SEIR, Appendix B6, Low-Level Health Risk Assessment, **Table 9**, in this document shows the acute HHI from the seven compounds with an acute health threat. The acute HHI of 0.1618 is below the 0.5 HHI significance threshold for acute non-cancer health impacts. Therefore, acute health impacts are considered less than significant.

4.2.10 Project Consistency with Applicable Plans

As mentioned previously, a significant impact would be generated if a project is inconsistent with the goals and policies of local and regional air quality plans. As indicated in the *SCAQMD CEQA Air Quality Handbook*, an EIR should discuss the project consistency with the most recent AQMPs. Several of the key underlying assumptions contained within those plans include the following requirements: (1) assumptions such as the number and location of population, housing units, and employment as contained in SCAG's Regional Comprehensive Plan and Guide, Growth Management Chapter and Growth Management Plan (GMP); (2) assumptions concerning the type, size, and location of transportation infrastructure as contained in SCAG's Regional Mobility Element; and (3) consistency with local plans and policies as contained in the City of Los Angeles General Plan, Air Quality Element.

Air Quality Management Plan

CEQA requires that projects are reviewed for consistency with the AQMP. A consistency determination plays an essential role in local agency's review of a project by both linking local planning with the attainment of the AQMP. Additionally, this analysis provides the local agency with ongoing information, thus assuring local decision-makers that they are making real contributions towards regional clean air goals.

New or amended general plan elements, specific plans, and regionally significant projects need to undergo a consistency review because the AQMP's strategy is based on projections from local planning documents. Projects that are consistent with local general plans are considered to be consistent with the regional AQMP. The proposed project will require a General Plan Amendment, and it is of a nature and a size to be considered significant in its air quality emissions; therefore, a consistency determination is considered necessary.

There are two key indicators of consistency with the AQMP: (1) whether the project will result in an increase in the frequency or severity of existing air quality violations or cause or contribute to new violations or delay timely attainment of air quality standards or the interim emissions reductions specified therein; and (2) whether the project will exceed assumptions for growth or regional distribution used in the emissions projections for the year 2010 or increments thereof based on the year of project buildout and phase. The following presents the methodology for a finding of consistency with the AQMP.

Determination of consistency with the AQMP is addressed in SCAG's *Guidelines for Implementation of 1989 AQMP Conformity Procedures*, March 1990. In accordance with that document, a project conforms with the AQMP if the following consistency requirements are met:

- The project improves or has a neutral effect on the jobs/housing balance. As addressed for the Regional Comprehensive Plan and Guide (RCPG) below, the project will incrementally increase jobs in a "job-rich" region within the City; however, the County portion of the project site is located within a "job-poor" region and will positively contribute to job opportunities available within this region.

- The project is required to demonstrate that vehicle trips (VTs) and VMT have been reduced to the extent feasible by implementing transportation demand strategies. The recommended mitigation measures include means to reduce VT and traffic congestion to the extent feasible. ~~The traffic~~ Section 4.13.1, ~~Traffic~~ Transportation and Circulation, Table 4.13-9, lists roadway improvements focused on reducing vehicle congestion and concludes that the level of service on traffic routes will not be degraded below acceptable levels. Adherence to these mitigation measures ensures compliance with this requirement.

- The project's environmental document should provide an analysis to demonstrate the following: (1) that the project will not have a significant negative impact on air quality in the long term (5 years or longer), demonstrated through improvement of the jobs/housing balance and reduction in VMT/VT; (2) that the transportation, land use, and energy conservation control measures are used to the extent possible to mitigate the impact on air quality; and (3) that the impact on air quality be analyzed on a subregional level.

- The impact analysis demonstrates that significant levels of air pollutants will be generated over the long term. However, it must be realized that the exhaust and particulate emissions associated with project implementation would be associated with another landfill project. The AQMP predicts that in the year 2010 the SCAB will experience a 34-percent increase in population with a 47-percent increase in VMT. Even with an increased awareness in the necessity for recycling, this increased population will require additional disposal of refuse.

The most recent version of the AQMP (Draft 1997 Air Quality Management Plan, August 1996) has now been released and is currently undergoing review. Recently, the 1997 AQMP was adopted by the SCAQMD and has been approved by the CARB. This plan has not yet received final approval from the USEPA as part of the State Implementation Plan revision. The 1997 Draft AQMP is based on the 1994 AQMP and carries forward most of the strategies included therein. However, with recent findings by nationally recognized health experts, the new 1997 Draft AQMP puts greater emphasis on PM_{10} particulate matter. In fact, the 1997 Draft AQMP is the first plan required by federal law to demonstrate attainment of the federal PM_{10} ambient air quality standards. The Draft 1997 AQMP also updates the demonstration of attainment of ozone and carbon monoxide. Additionally, because the Basin came into attainment of the federal nitrogen dioxide standard since the prior AQMP was prepared, the 1997 Draft AQMP includes a maintenance schedule to assure continued compliance.

The 1997 Draft AQMP also addresses several State and federal planning requirements and incorporates new scientific data, primarily in the form of updated emissions inventories, ambient measurements, and new air quality models. Expanding on the control strategies included in the 1994 AQMP, the 1997 Draft AQMP

projects sufficient emissions reductions to meet all federal criteria pollutant standards within the time frames allowed under the federal Clean Air Act.

The 1997 Draft AQMP also addresses notable regulatory rules promulgated since the preparation of the 1994 AQMP. These include the implementation of Phase II reformulated fuels in 1996, the replacement of Regulation XV rideshare program with an equivalent emission reduction program, and new incentive programs for generating emission credits. Other highlights of the 1997 Draft AQMP are noted below.

- use of the most current air quality information (1995), including special particulate matter data from the PM_{10} Technical Enhancement Program;
- improved emissions inventories, especially for motor vehicles, fugitive dust, and ammonia sources;
- a similar, but fine tuned overall control strategy with continuing emphasis on flexible, alternative approaches including intercredit trading;
- a determination that certain control measures contained in the 1994 AQMP are infeasible, most notably the future indirect source measures;
- enhanced modeling for particulates;
- separate analyses for the desert portions within the District's jurisdiction: the Coachella Valley within the newly designated Salton Sea Air Basin, and the Antelope Valley within the Mojave Desert Air Basin.
- attainment to the federal Post-1996 Rate-of-Progress Plan and the Federal Attainment Plans for ozone and carbon monoxide;
- a maintenance plan for nitrogen dioxide; and
- an attainment demonstration and State Implementation Plan Revision for PM_{10}.

Regional Comprehensive Plan and Guide

Growth Management Chapter

In addition to demonstrating consistency with the AQMP, regionally significant projects should provide consistency with the Regional Comprehensive Plan and Guide, Growth Management Chapter, which incorporates by reference portions of the GMP. The growth management chapter presents baseline and future socioeconomic data and policies for anticipated growth within the SCAG region up to the year 2015. These projections are used by agencies in developing long-term programs for improving the SCAB and regional mobility strategies. This chapter also provides guidance in addressing growth and land use patterns that would reinvigorate the economy, avoid social and economic inequities, curb geographical dislocation of communities, and maintain the quality of life in the region.

Relevant policies applicable to the proposed project include the following:

- SCAG shall encourage patterns of . . . land use which reduce costs in infrastructure construction and make better use of existing facilities.[12]

- SCAG shall encourage existing or proposed local jurisdictions programs . . . which . . . create opportunities for residents to walk and bike.[13]

Consistency with the Growth Management Chapter is determined by performing an analysis of the project and providing comparisons with the population, housing, and employment forecast presented in this chapter for the year 2010. The AQMP requires that the regional jobs/housing balance (as well as many other variables) be taken into consideration in the prediction of future air quality. If development within the project area has been considered in the Growth Management Chapter, the project will generally be found to be consistent with the AQMP.

SCAG's 1989 GMP presented SCAG's forecasted distributions to the year 2010. This plan incorporated a regional job/housing balance policy. The goal of the job/housing balance policy was to relieve the pressure of population and job growth on the transportation system by achieving more balanced future development. A region is considered balanced if the employment-to-housing ratio is 1.27 in the year 1984 and 1.22 in the year 2010.[14] Ideally, each city within the Southern California area could achieve this ratio and attain the overall jobs/housing balance, thereby reducing the need for extended commuter trips. However, this is not practical since the locations of existing employment centers and housing areas tend to be grouped as a result of local land use planning, as well as budgetary and practical constraints. Furthermore, a balance of jobs to housing does not ensure that the jobs will be filled by local residents. As a result, the overall ratio is examined from both a subregion and subarea basis.

The project site (within the City) is located in the San Fernando Valley subarea and the Los Angeles City subregion. The Los Angeles City subregion comprises the Cities of Los Angeles, Calabasas, Malibu, San Fernando, Hidden Hills, and various unincorporated areas. This subregion includes the geographical subareas of the San Fernando Valley, Santa Monica Mountains, most of the westside area, central downtown area, and Los Angeles Harbor area. The San Fernando Valley subarea, located closest to the project site, is characterized as urban, except for the northern periphery that includes hillside lands, publicly owned open spaces associated with major flood control dams and spreading basins, and equestrian communities. The predominant land use in this subregion is single-family residential.[15]

As indicated within the GMP the San Fernando Valley subarea had a jobs/housing balance ration of 1.28 in 1984 and a projected ratio of 1.26 for the year 2010, thereby classifying this subarea as "jobs rich." As updated by SCAG, the revised jobs/housing balance for the San Fernando Valley subarea was 1.50 in 1987

12/ *Regional Comprehensive Plan and Guide*, Southern California Association of Governments (SCAG), p. 3-23. March 1996.

14/ *Regional Growth Management Plan*, Southern California Association of Governments (SCAG), p. VI-1. February 1989.

15/ *Final Environmental Impact Report, Regional Transportation Plan and Chapters of the Regional Comprehensive Plan, Volume I: State of the Region Report*, SCAG, pp. 1.21 and 1.22. May 1994.

and is projected to be 1.31 by 2010.[16] The Los Angeles City subregion had a job/housing ratio of 1.35 in 1994 and is projected to have a jobs/housing ratio of 1.43 by 2010. This ratio also indicate a "jobs rich" subregion. As referenced within the RCPG, by 2010 approximately 2,213,000 jobs are projected within this subregion. This is an increase of 248,000 jobs (or 12.62 percent) above the 1990 job level of 1,965,000.[17] Since the project will create additional jobs within the region without providing additional housing, the project will not positively contribute to the attainment of the stated objective. However, because the number of jobs associated with the project is minimal (i.e., 35 jobs of the total 248,000 jobs projected to occur between the years 1984 and 2010), it will not significantly affect the current balance or adversely affect the attainment of the regional goal.

The project site (within the County) is within the Santa Clarita subarea, which has a jobs/housing ratio of 1.18 for the year 2010, making this region "jobs poor." The North Los Angeles subregion (within the County) also is identified as "jobs poor" with a projected 2010 jobs/housing ratio of 1.14.[18] ~~Therefore~~ Implementation of the project would therefore serve to improve the jobs/housing balance in this subarea and subregion by providing additional job opportunities.

The proposed general plan amendment required for the project could result in less residential growth in the Los Angeles City subregion and San Fernando Valley subarea than projected in the RCPG. Based on the site's existing land use and zoning designations (i.e., Open Space, A1-1-O), residential uses could be developed at a density of 0.5 to 1 dwelling unit per acre. However, because the project site includes an inactive landfill and an operating County Landfill, residential use onsite would not be a feasible option at this location.

The development of a landfill within this project site would significantly reduce infrastructure costs since many existing improvements (e.g., utilities, access roads, ancillary facilities, environmental protection and control systems) that currently service the inactive landfill (City) and operational landfill (County) could be used. If project development does not occur, transportation or hauling costs to other landfill facilities located either in-County or out-of-County would increase due to greater travel distances. Additionally, the development of the proposed project would minimize many significant environmental impacts, such as biological resources, development of new infrastructure, air quality emission impacts associated with new site development, or the exportation of wastes to other landfill sites. The dedication of Bee Canyon and East Canyon associated with the previous County Landfill project approval, would provide linkage to regional hiking and equestrian trails as described in Section 4.14.4, Parks and Recreational Resources.

Air Quality Chapter

The air quality chapter sets forth SCAG policy for participating in, responding to, and implementation of regional air quality plans. SCAG prepared the regional AQMP and uses this plan to determine conformity to transportation projects that use federal monies and the State Implementation Plan (SIP). The SIP implements, maintains, and enforces primary and secondary National Ambient Air Quality Standards. These

[18]/ "Southern California Association of Governments 1996 Regional Growth Forecast". Facsimile. October 4, 1996.

federal standards are further described within this section. Project impacts on regional air quality are also analyzed within this section.

Regional Mobility Element

Referencing the *SCAQMD CEQA Air Quality Handbook*, "if the project is a transportation project, it should be compared to the assumptions in the Regional Mobility Plan: Information on Transportation Corridors, 1989, concerning the type, size and location of the project. The comparison is necessary because many of these transportation projects are relied upon in the AQMP (1991 AQMP) to reduce emissions." The Regional Mobility Plan has been updated by the 1994 Regional Mobility Element. Although several traffic-related improvements will mitigate transportation and circulation impacts as a result of the proposed project, the project is not a "transportation project" in the context of the Regional Mobility Element and therefore cannot be directly compared to the plans and policies contained therein.

Congestion Management Program

Conformity with the Los Angeles County Congestion Management Program (CMP) requires that the project be compared with the stated goal of obtaining certain levels of service on established CMP roadways. None of the key intersections within the project area are considered CMP intersections, and the project will not exceed the threshold criteria of 150 trips during the peak hour, which would necessitate a freeway CMP analysis. As a result, no CMP consistency determination is necessary for the project.

Los Angeles Clean Air Program

The Los Angeles Clean Air Program (CAP), adopted in December of 1992 provides implementation strategies for achieving federal, State, regional, and local air quality goals and mandates. The program is based on the goals and policies included in the 1991 AQMP. The CAP is a dynamic program and considers both on-going and historic measures and allows elected officials and City staff examination of both past and current trends in the attainment of clean air.

Included in the CAP are various measures, many of which are directly referenced to the AQMP. These measures, considered as feasible for implementation address airport and harbor operations, energy and conservation, land use strategies, Public Works operations, dust suppression, transportation, and governmental administrative controls. The City currently incorporates goals and policies and implementation strategies contained in the 1997 Draft AQMP.

City of Los Angeles Air Quality Element

The City of Los Angeles Planning Department has adopted an Air Quality Element as an optional element of the City of Los Angeles General Plan. As stated therein, the purpose of the Air Quality Element is to promote the attainment of the NAAQS and CAAQS and support areawide economic growth. The Air Quality Element specifies performance-based standards to meet its objectives.

Presented below are some of the element's primary goals applicable to the proposed project.

Goal 1. Supports consistency with the AQMP and sustenance of Citywide economic growth to obtain good air quality. AQMP consistency was discussed previously. Economic growth in the City will be supported by the provision of additional local landfill capacity. Since waste hauling costs increase with the distance

traveled, the expansion of a local landfill will provide a cost-effective disposal site proximal to the waste generation sources. Development of the proposed project would be consistent with this goal.

Goal 2. Promotes the reduction in single-occupant VTs. Because only 35 employees are associated with proposed landfill operations and 52 employees currently facilitate County landfill operations, the project would not be subject to SCAQMD's Rule 2202 (On-Road Vehicle Emissions Mitigation Options), which requires employers of more than 250 workers at one location to reduce motor vehicles through ridesharing or other programs. ~~However, since projected emissions exceed daily threshold criteria, project-related mitigation measures specify methods to encourage ridesharing and thereby ensure attainment of this goal.~~

Goal 3. Increase the number of work trips via transit and reduce vehicular traffic during peak periods. Mitigation measures aimed at meeting Goal 2 (above) will aid in achieving this goal. The goal of reducing traffic during peak-hour periods will be supported by restricting the operational hours of the landfill site. Moreover, transfer trucks that haul partial loads will be penalized, thereby encouraging full loads and reduced truck movement.

Goal 4. Minimize impacts of land use development on air quality. Review of the project is occurring at the local level. This will ensure that the relationship between land use, transportation, and air quality is in balance with the nature of the project. Air quality impacts will be considered during the City's decision-makers review of the project. The analyses of air quality impacts caused by the proposed project include both a CEQA analysis and a stand-alone health risk assessment. Vehicle trips would be reduced through implementation of the mitigation measures presented and the development of a local, rather that a more distant landfill facility. The air pollutants emitted from the flare station, which is a pollution control device, were shown to induce no potential adverse health effects.

Goal 5. Improve energy efficiency primarily at City facilities. Private developments should encourage waste reduction and recycling as part of this goal. The proposed project would include development of a green waste and wood waste ~~recycling and public drop-off~~ area to support recycling efforts. Another part of this goal is to reduce the use of polluting fuels in stationary sources in favor of electric or low-emitting fuels. LFG will be destroyed through the flaring stations; however, the amount of energy resources expended in this process is not expected to be significant and would be provided by the City Department of Water and Power (DWP). In later stages of landfill development, the gases that would be collected through the LFG collection and disposal system may be combusted to produce electricity.

CUMULATIVE IMPACT

Table 3.2-1 lists the 33 related projects associated with cumulative project development. These projects range from small residential developments that would not be expected to produce significant air quality impacts of themselves (e.g., five single-family lot subdivision on 1.78 acres) to large projects that probably cannot be mitigated to a less than significant level (e.g., 1,895,000 square feet of industrial, 105,000 square feet of commercial, 34 single-family units, and 120 recreational vehicle spaces all on 249.4 acres).

As noted in **Table 4.2-8**, the single greatest source of project-generated emissions is from vehicles transporting refuse to the project site. Vehicle emissions are also the greatest source of air pollutants for the identified cumulative projects. Because the emissions associated with construction and operation of the cumulative projects cannot be determined without a full analysis of each project (including a traffic study), the cumulative analysis for the project's air quality must be generic by nature.

The project area is currently out of attainment for both O_3 and PM_{10} suspended particulate matter pollutants. Construction and operation of cumulative projects will further degrade the local air quality, as well as the air quality within SCAB. Air quality will be temporarily degraded during construction activities that occur separately or simultaneously. However, the greatest cumulative impact on ~~the quality of~~ regional air quality will be the incremental addition of pollutants primarily from increased traffic associated with the development of residential, commercial, and industrial projects and the use of heavy equipment and trucks associated with construction of these projects.

The *SCAQMD CEQA Air Quality Handbook* provides methodology to determine whether a project is cumulatively significant. In accordance with the *SCAQMD CEQA Air Quality Handbook* (pp. 9-12), if a project can reduce emissions by 1 percent per year to the year 2010, it is not considered cumulatively significant. This analysis is performed through a comparison of unmitigated and mitigated emissions and by dividing the projected reduction (in percent) over the period from project operations to the year 2010. This would require that mitigation attain a control efficiency of 14 percent for operations beginning in 1996.

As demonstrated in **Table 4.2-148**, NO_2, ~~SO_2~~, and PM_{10} are projected to exceed this ~~14 percent~~ reduction. However, both CO and ROG primarily associated with vehicular travel as well as, SO_2 associated with the combustion of landfill gas are not expected to achieve this reduction, and the project is considered significant on a cumulative level.

CITY MITIGATION MEASURES

4.2.11 Construction

Site construction will create exhaust pollutants from onsite earth movement and the employment of heavy equipment. A comparison between project emissions and the levels considered by the SCAQMD to be potentially significant illustrates that NO_x emissions are expected to exceed the SCAQMD threshold criterion and mitigation would be necessary. Mitigation for heavy equipment is limited. However, the following mitigation measures will reduce these emissions to the maximum extent reasonably feasible.

Exhaust Emissions

- The project proponent will maintain equipment in tune per manufacturer's specifications.
- The project proponent will use catalytic converters on gasoline-powered equipment.
- The project proponent will retard diesel engine injection timing by 2 degrees.
- High-pressure fuel injectors will be installed.
- Heavy equipment will use reformulated, low-emission diesel fuel.
- The project proponent will substitute electric and gasoline-powered equipment for diesel-powered equipment where feasible.
- Where applicable, equipment will not be left idling for prolonged periods.

- The project proponent will curtail (cease or reduce) construction during periods of high ambient pollutant concentrations (i.e., Stage II smog alerts).

Presented in **Table 4.2-147** are the construction exhaust emissions, the anticipated efficiency of these control measures, and the residual impact. Note that the control efficiency of the proposed mitigation measures is based on best estimates of values presented in the ~~*SCAQMD CEQA Air Quality Handbook*, AP-42, and past conversations with CARB and SCAQMD personnel~~ staff report "Initial Statement of Reasons for Proposed Rulemaking, public hearing to consider the adoption of regulations regarding the California Exhaust Emission Standards and Test Procedures for new 1996 and later heavy-duty off-road diesel cycle engines and equipment engines," released by the CARB on January 9, 1992. As depicted in this table, even with the implementation of the mitigation measures, NO_x emissions are projected to remain significant.

Fugitive Dust

Dust from construction activities, including physical site disturbance, material deliveries, employee commuting, and potential wind erosion during high wind episodes, may create a visual and soiling nuisance beyond the property line. Because dust impacts are expected to be significant during the construction phase, standard mitigation measures (by project design) will be implemented to control fugitive dust emissions during construction as required by SCAQMD Rules 402 (Nuisance) and 403 (Fugitive Dust).

The following mitigation measures will reduce fugitive dust emissions during construction activities at the landfill facility:

- Daily watering of active construction areas, active soil stockpiles, and all traveled unpaved roads shall be performed to minimize dust lofting from construction disturbances. Construction areas will also receive a soil stabilization (sealant) product if they are to be left unattended for periods in excess of 5 days.

- Wind speed shall be continually monitored using onsite anemometers. Excavation within construction areas shall be halted when the 15-minute average wind speed exceeds 15 mph or when the instantaneous wind speed exceeds 25 mph.

- Graded areas shall be watered as necessary to reduce dust emissions.

- Disturbed areas shall be revegetated with an interim ground cover as specified in the proposed revegetation plan. Excavation will proceed in a manner to reduce the amount of graded areas at any given time.

- Public streets (i.e., San Fernando Road) shall be swept at the conclusion of construction work.

As depicted in **Table 4.2-147**, even with the implementation of the mitigation measures, PM_{10} emissions, due mainly to dust generation, are projected to remain significant.

Source: Ultrasystems Environmental Incorporated

Notes:

1. All emissions are in pounds per day. Mitigation measures are as presented in the text. Where available, control efficiencies are considered conservative for SCAQMD and CARB control factors. Where no control efficiencies are published, control efficiencies are speculative but considered conservative based on various reports and bulletins published by the CARB and discussions with CARB and SCAQMD staff.
2. Mitigation is inherent in emissions calculated using manufacturer specifications or EMFAC7G. Therefore, no mitigation control efficiency was applied to heavy equipment emissions calculated using these methodologies.

4.2.12 Operations

Exhaust Emissions

As shown in **Table 4.2-8**, exhaust emissions from project operations are anticipated to exceed the significance criteria for CO, NO_x, SO_x and ROG. Additionally, the 289.1 pounds of PM_{10} produced as a combustion by-product would be additive with the 688.9 pounds of PM_{10} associated with fugitive dust, resulting in a combined daily total of 978.0 pounds. This value also exceeds its respective significance criterion. Therefore, significant air quality impacts are ~~anticipated~~ projected to remain significant.

Construction Equipment

The applicant will implement same mitigation measures during operations for heavy equipment as presented for site construction.

- The project proponent will maintain equipment in tune per manufacturer's specifications.
- The project proponent will use catalytic converters on gasoline-powered equipment.
- The project proponent will retard diesel engine injection timing by 2 degrees.
- High-pressure fuel injectors will be installed.
- Heavy equipment will use reformulated, low-emission diesel fuel.
- The project proponent will substitute electric and gasoline-powered equipment for diesel-powered equipment where feasible.
- Where applicable, equipment will not be left idling for prolonged periods.
- The project proponent will curtail (cease or reduce) construction during periods of high ambient pollutant concentrations (i.e., Stage II smog alerts).

Refuse Trucks

In addition to the mitigation measures presented for onsite operations, the project proponent has made a commitment to reduce traffic congestion with the recommended traffic mitigation measures stated in Section 4.13, Transportation and Circulation. These measures include recommendations for roadway improvements that will reduce any vehicle queuing at the landfill, thereby reducing idle emissions. These mitigation measures will reduce air quality impacts from all vehicles entering the landfill.

Most of the refuse trucks delivering waste loads to the landfill are not operated by the project proponent. Therefore, the project proponent has no control over these emissions. However, the project proponent does have some control over emissions generated from project proponent-operated trucks and any other refuse trucks, once these trucks are onsite.

The following measures will be applied to the project proponent's operated trucks that utilize the project site:

- Refuse trucks shall be maintained in proper tune. Trucks observed to emit excessive amounts of smoke (particulate matter) shall either be tuned up or repaired, as applicable.

- Where applicable, high-pressure fuel injector nozzles shall be used, and diesel engine timing shall be retarded by 2 degrees.

The following measures will be applied to all refuse trucks accessing the project site:

- Using a progressive fee schedule, the project proponent shall encourage trucks to carry full loads.

- The project proponent shall encourage trucking to be performed during off-peak hours. This shall be accomplished through coordination of deliveries with the transfer stations that supply refuse, restrictions in the hours of operation, and/or a fee schedule that penalizes haul trucks arriving during peak congestion periods. This will reduce emissions by increasing truck speeds and eliminating prolonged idling in traffic.

- When operating onsite, trucks shall not be left idling for periods in excess of 5 minutes.

- Private owner-operators shall be warned that, if their trucks emit excessive amounts of smoke as determined by scale house workers, they will not be allowed future access to the landfill facility.

The landfill gas flares emit significant amounts of CO, NO_x, SO_x, ROG and PM_{10}. They are required by the SCAQMD to be constructed using Best Available Control Technology (BACT) which represents the lowest achievable emission rate utilizing currently available technology. Even after the installation of BACT, emissions would remain significant.

Table 4.2-158 recounts the projected operational emissions, projected control efficiencies of the mitigation measures, and residual emissions. It is expected that the inclusion of these recommended mitigation measures will reduce emissions to the extent feasible but is not anticipated to reduce them to a level of less than significant.

Fugitive Dust

Fugitive dust emissions in combination with PM_{10} emissions generated from vehicular and flare exhaust are anticipated to create a significant impact. This would be especially true during above-average and occasionally high wind conditions (i.e., Santa Ana). Past operations have shown that the higher-elevation upper plateau and southern berm areas of the existing inactive landfill have experienced greater wind-

Notes:

1. All emissions are in pounds per day. Mitigation measures are as presented in the text. Where available, control efficiencies are considered conservative for SCAQMD and CARB control factors. Where no control efficiencies are published, control efficiencies are speculative but considered conservative.
2. Mitigation is inherent in emissions calculated using manufacturer specifications or EMFAC7G. Therefore, no mitigation control efficiency was applied to heavy equipment emissions calculated using these methodologies.
~~2~~3. Although mitigation measures are proposed to reduce these emissions, the overall control efficiency will be very low and is not considered in this analysis.
~~3~~4. This value is the result of thermal destruction of LFG from 5 flares at the permitted levels.
~~4~~5. See **Table 4.2-169**.

generated fugitive dust occurrences than the lower elevations within the canyon. The lack of revegetation on the active face of the landfill surface has exacerbated difficulties in adequately controlling fugitive dust emissions during periods of high wind conditions. However, the project proponent has successfully established ground cover and other revegetation on portions of the existing inactive landfill site. Additionally, the project proponent has implemented enhanced soil treatment measures to stabilize soil conditions and further enhance onsite revegetation.

The proposed project would be located farther away from adjacent urban land uses than the existing inactive City Landfill. The closest residential unit to the proposed landfill footprint is approximately 1,700 feet. Although the more sheltered location of proposed landfill operations relative to the existing inactive landfill site may reduce, to some extent, the likelihood of fugitive dust generation, the site would still be subject to winds conditions that have created prior dust control problems at the existing facility. Therefore, the project proponent shall be required toprovide adequate mitigation measures to control fugitive dust in accordance with the SCAQMD Rules 402 and 403 and to minimize offsite migration of windblown dust from the landfill extension site.

Mitigation measures and control efficiencies for each dust-generating operation are presented in the following discussion. **Table 4.2-~~16~~19** includes the unmitigated emissions, assumed control efficiency, and the mitigated emissions for landfill operations.

Truck Travel and Fugitive Dust Emissions

The following mitigation measures shall be implemented by the project proponent:

- To minimize fugitive dust emissions, the access roadways shall be paved and haul roads to the working face areas shall be hard packed with crushed stone. Paved and/or ~~gravel~~ crushed stone covered roadways shall extend up to new active fill areas as development of the landfill progresses. Crushed stone may consist of purchased rock, recycled asphalt, recycled cement, and/or recycled rock.

For paved roads, mitigation shall include:

- Use of curbs and gutters. At least twice daily watering or wet sweeping to remove windblown surface dust. AP-42 assigns a control efficiency of 50 percent for twice weekly cleaning of industrial paved roads. With twice daily cleaning, a control efficiency in excess of ~~95~~0 percent is predicted.

Notes:

*1: Control efficiencies are in accordance with *AP-42: Compilation of Air Pollutant Emission Factors,* op. cit., and ~~are conservative.~~ *Draft South Coast Air Quality Management District Consultation No. 4, Work in Progress Air Quality Analysis Refinements El Sobrante Landfill Expansion,* TRC Environmental Solutions, Inc., May 2, 1997.

2. Does not include truck turnaround area.

3. Represents worst-case daily emissions.

~~3~~4. Includes truck turnaround area.

~~4~~5. Mitigation Control Efficiency was derived by dividing Residual PM_{10} Emissions in (lb/day) by Unmitigated PM_{10} Emissions in (lb/day).

For unpaved clay roads, mitigation shall include:

- The regular application of ~~an~~ SCAQMD-approved chemical dust suppressant with a manufacturer's demonstrated control efficiency ~~of 80~~ in excess of 90 percent and subsequent watering. Note that this control efficiency is less than (i.e., more conservative than) the 95 percent value used at the El Sobrante Landfill (*Draft South Coast Air Quality Management District Consultation No. 4, Work in Progress Air Quality Analysis Refinements El Sobrante Landfill Expansion*, TRC Environmental Solutions, Inc., May 2, 1997).

For unpaved crushed stone covered roads, mitigation shall include:

- With the use of a crushed stone topcoat consisting of purchased rock, recycled asphalt, recycled cement, and/or recycled rock, in addtion to the regular application of a SCAQMD-approved chemical dust suppressant and subsequent watering, a control efficiency in excess of 95 percent is predicted.

To reduce the amount of dust being carried onto San Fernando Road, mitigation shall include:

- The placement and proper operation of a wheel washer for trucks at the site exit to minimize dust and dirt entrainment prior to trucks leaving the site.

Heavy Equipment Operations

Fugitive dust associated with w~~W~~ind erosion and heavy equipment involved in landfilling waste, procuring cover material, ~~excavating~~ preparing ~~new~~ landfill ~~cells~~ areas, and covering active working cells ~~is~~ are projected to add as much as ~~77~~ 74.1 pounds of PM_{10} per day. (Note that this value does not include the ~~35~~ 8.6 pounds per day estimated for erosion of ~~an initial~~ stockpile that will be constructed during initial site construction and depleted for daily cover. It will not ~~to~~ be reconstructed.) In addition, onsite travel will add an additional 606.2 pounds of PM_{10} per day.

As required by SCAQMD Rule 403, these emissions will be controlled using a water truck with a projected dust-reduction efficiency of at least ~~50~~ 65 percent.

~~Additionally,~~ Mitigation pertaining to heavy equipment operations ~~and site erosion~~ shall include the following:

- Operations shall be restricted to encompass no more than a 10-acre active working face area.

- To the extent technically feasible, material excavated from one portion of the project site shall be used as daily cover material in an adjacent area to minimize travel distances for such cover material.

With the inclusion of these additional measures, control efficiency is estimated to be in excess of 65 percent. This value is more conservative than the 68 percent value used in the El Sobrante Landfill documentation.

Additionally, mitigation pertaining to site erosion shall include the following:

- Subject to approval by the California Integrated Waste Management Board (CIWMB), filling in each active area shall be prolonged through the utilization of a 20-foot maximum cell height. This would

reduce the area of excavation and minimize the disturbances to the landfill, thereby providing an effective control of fugitive dust.

- A temporary vegetation cover shall be established on all slopes that are to remain inactive for a period longer than 180 days.

- An SCAQMD approved soil stabilization (sealant) product shall be used to retard soil erosion and enhance revegetation. Soil sealant shall be applied when necessary to selected working areas of the landfill. The sealant will also be used as a binder or tackifier to hold seed during revegetation, mulch, and fertilizers in-place until grasses become established and stabilize on the landfill surface.

Control efficiency of site erosion is estimated to be greater than 90 percent.

However, even after the incorporation of mitigation measures, PM_{10} emissions are projected to remain significant. **Tables 4.2-20-1, 4.2-20-2, and 4.2-20-3** provide a summary of source by source uncontrolled and mitigated PM_{10} emissions for worst-case daily emissions of road dust, the disturbed area, and exhaust, respectively.

COUNTY MITIGATION MEASURES

For a discussion of adopted County Landfill mitigation measures, timing, and monitoring responsibilities, with respect to air quality refer to Appendix C9, FEIR Mitigation Monitoring and Reporting Summary, pp. 24-27, within this Draft SEIR. Implementation of the proposed project shall require an amendment to this Summary to provide for the development of ±42 acres in the County portion of Sunshine Canyon. The same mitigation measures imposed for the County Landfill project would be adopted for this development in the County. (Refer to Appendix C17, Amended Mitigation Monitoring and Reporting Summary.)

LEVEL OF SIGNIFICANCE AFTER MITIGATION

The mitigation measures would reduce impacts; however, even with the implementation of these mitigation measures, project-generated and project related cumulative impacts are considered significant and unavoidable.

4.2.13 Odor Impacts[19]

ENVIRONMENTAL SETTING

Waste materials received on a daily basis at the proposed City/County Landfill have the potential to emit detectable odors prior to the application of daily cover material. Two potential sources of odors are generally associated with most landfilling operations. The first source of odor is directly related to the specific types of refuse brought to the landfill prior to emplacement, compaction, and the application of daily cover material. The second source of odor is from the methane-related gases produced from the anaerobic (oxygen-free) microbial decomposition of organic matter in the buried refuse.

Source: Browning-Ferris Industries

The first potential source of odor is produced from the decomposition of refuse in a landfill and is primarily based on factors that include the type of materials comprising waste, age of the refuse, acidic content of the waste (pH level), moisture content in the refuse, degree to which the refuse is compacted at the landfill, particle size, temperature, and degree of mixing and types of organics present.

Additionally, certain types of household wastes, including cooked and uncooked foodstuff and meats, green waste, and wet wood shavings, may begin decomposition before being delivered to the landfill. These types of wastes release low levels of distinct scents that can contribute to odor levels. In addition, the waste stream will change seasonally. For example, many communities produce greater levels of yard waste during the spring and summer seasons. Waste generation usually falls during the late fall and winter periods. An exception takes place during the holiday season (i.e., Christmas) where many communities experience large increases in paper and packaged goods.

By receiving the refuse, compacting it, and covering it with a minimum layer of 6 inches (i.e., State standard) of cover material at the end of each working day, the potential for these odors is substantially reduced. The odors that may be released directly from the refuse prior to being covered with cover material are usually at low levels and are dispersed in the atmosphere at levels of concentration below which they do not create a nuisance to local receptors. The proposed landfilling operations are located at sufficient distances from the potential receptors (residential) and separated by sufficient terrain (1,700 feet to the nearest residence) so that no odor nuisance from refuse emplacement should occur. Additionally, between the proposed City/County Landfill footprint and the residential areas in Granada Hills, formidable barriers to odor migration include the inactive landfill, which is approximately 300 feet in height, and a ±100 acre buffer area. These two features pose sufficient screening and distance to inhibit the transmission of odors beyond the project site boundaries.

The second source of odor is produced by the anaerobic microbial decomposition of organic matter in refuse that produces natural LFGs. CO_2 (38 to 46 percent) and methane (53 to 60 percent) are the two main constituents of the natural gases produced, neither of which has a perceptible odor to humans. However, trace amounts of other gases that are malodorous are also produced during anaerobic decomposition. As the natural gases are generated within the landfill cells, internal landfill cell pressures move the gases within and away from the landfill along paths of least resistance. Generally, anaerobic processes begin locally and are then followed by the depletion of oxygen in isolated pockets. Processes peak in CO_2 production that typically occurs approximately 11 to 40 days after refuse emplacement. The methane-forming microorganisms begin formation approximately 1 to 2 years after landfilling.

~~The amount of gas produced by the landfill was predicted by comparison of gas flow to the existing flare and known refuse volume to a predicted City/County Landfill volume of 90 million tons. Estimated gas generation is on the order of 4.0 million cubic feet per day (Mcfd). (Note that the health risk assessment was based on a maximum daily generation rate of 6.3 Mcfd.) In 1989 projections were made regarding the LFG generation for the combined County/City Landfill Project (215-million-ton landfill facility). Note that the 4.0 Mcfd value is far less than the previously modeled data. Revisions in LFG generation calculations, as well as experience gained in the generation rates associated with the existing inactive landfill, have shown gas generation to be substantially lower than previously believed.~~

Odors can occur when the landfill surface, due to differential waste settlement, subsidence, or cracks, allows the LFG to escape into the atmosphere. At the existing inactive landfill, cracks found on the landfill surface are filled as part of a continuous maintenance programs. A similar procedure would be performed on the proposed landfill footprint area.

The proposed LFG collection and flaring system would be installed to collect gases generated by the decomposition of refuse through a series of horizontal and vertical gas collector wells designed to minimize the potential of onsite and offsite gas emissions and odors. The proposed LFG collection and disposal system would consist of gas extraction wells and installed piping. This system would be constructed of polyethylene pipe, which would flex as differential settlement occurs at the landfill. Once LFG is generated, it would be drawn into the horizontal collectors or wells and subsequently to the collection piping system by the vacuum blowers. To avoid drawing air into the system, the gas is extracted at the same rate it is being produced by controlling the vacuum level in the piping system. Extraction wells would be spaced so that the volume of refuse influenced by the wells is sufficiently balanced to capture the maximum amount of gas being generated by the landfill. The wells would be located so that the volume of well influence will slightly overlap that of the adjoining wells. Furthermore, project-engineering practice dictates that the collection system piping be sized so that sufficient vacuum is available to all wells in the system.

The horizontal gas collection system would be installed when preparing each new cell area and would be expanded as necessary to ensure compliance with SCAQMD Rule 1150.1 (Control of Gaseous Emissions from Active Landfills). Moreover, in order to control odors and help prevent potential migration of methane gas, ~~two~~ high-efficiency flares would be constructed ~~(in addition to the existing flaring station) in the City portion of Sunshine Canyon~~ to incinerate and destroy the collected gas. These proposed gas flaring stations would each have a total volume capacity of approximately 6 Mcfd.

Surface and ambient air monitoring is an ongoing regime dictated ~~throughout the landfill permitting process~~ by SCAQMD Rule 1150.1. Both the gas collection and flaring system and sampling program for the proposed extension will require approval by the SCAQMD. Surface sampling is used to identify areas of the landfill where gas may be escaping.

THRESHOLDS FOR DETERMINING SIGNIFICANCE

The *SCAQMD CEQA Air Quality Handbook* recommends that the following indicator be used as an air quality screening criterion for odors:

- creation of (or subject sensitive receptors to) an objectionable odor over 10:1 dilution to thresholds.[20]

ENVIRONMENTAL IMPACT

The proposed City/County Landfill Project would be operated in a manner to preclude odor nuisances emanating from the incoming refuse and/or landfill operations. The landfilling operations, including cell orientation, gas collection, and cover application, would effectively confine and seal in odors associated with deposited wastes within landfill areas.

Existing prevailing winds in the vicinity of the Santa Susana Mountains and Sunshine Canyon will help reduce the potential impact of any temporary odorous emissions. The prevailing 24-hour wind direction is south to southwest, away from sensitive receptors. Any other potential odor impacts will also be minimized by the large volumes of air masses associated with open space conditions, wind turbulence, and the intervening topography in the Sunshine Canyon area.

---

[20]/ A methodology established by the American Society of Testing Materials (ASTM, Standard Method D 1391) to determine how many times an air sample must be diluted with "clean" air before the odor is no longer detectable to an average adult with average odor sensitivity.

Based on an expected average intake rate of 11,000 tpd and a maximum intake rate of 12,100 tpd, it will be several years before landfilling occurs adjacent to the southern portion of the existing inactive landfill, which is now in the process of closure. The distance of separation between the proposed landfill footprint and the nearest residential receptor on the end of Timber Ridge (Granada Hills) is approximately 1,700 feet. This distance of separation should eliminate potential odor nuisance problems emanating from the working face area of the landfill.

Based on the volume of solid waste projected to be deposited at the proposed City/County Landfill, there will be an increase in the amount of LFG being generated. The potential for odor emissions from decomposing refuse exists at the proposed landfill and all landfill facilities. However, application of daily cover, as well as the expanded LFG collection and disposal system, is expected to effectively remove the gases produced and prevent any significant odor problems from developing.

During the prior landfill's (now in the process of closure) operation, concerns were raised in connection with odor emissions at the landfill. The SCAQMD, which regulates landfill odors, conducted numerous inspections and concluded that the existing landfill was not the source of odors that had caused complaints from residents within Granada Hills. The SCAQMD determined that the odor source was derived from natural sulfur compounds found in the adjacent watershed area or a nearby refinery that has since been closed. Sulfur compounds from the adjacent watershed area are naturally released into the air when groundwater reaches the surface through natural seeps and springs. These natural seeps and springs are located north and west of Sunshine Canyon, near Bee Canyon and O'Melveny Park, and adjacent to existing residential areas. Additionally, oil well extraction and gas injection storage operations located northerly of these existing residential areas are another potential source of odor emissions.

The SCAQMD further noted that the odor control procedures being implemented by the project proponent were effective in controlling refuse odors. Odor control measures used at the existing landfill when in full operation were proven to be effective at controlling odors at the landfill. The project proponent still uses odor control measures such as operation of the gas collection system and repair of cracks found in the landfill cover. Similar control measures will be utilized at the proposed City/County Landfill facility.

CUMULATIVE IMPACT

The development and operation of the proposed City/County Landfill Project in combination with current and future proposed projects located in the general vicinity would not result in any significant cumulative odor impacts. Odor impacts associated with the proposed project can be fully mitigated to a less than significant level.

CITY MITIGATION MEASURES

The mitigation measures listed and described below are designed to eliminate the potential for odor emissions to ambient air quality. The implementation of mitigation measures would reduce the potential for odor impacts to a less than significant level.

- The natural biological processes that generate odors in a landfill through anaerobic decomposition cannot be prevented or avoided. However, the LFGs shall be prevented from escaping to the atmosphere through the use of control measures. These measures include using daily and intermediate cover material over deposited wastes, filling any surface cracks with clean dirt as

necessary, and extracting LFG through the use of an LFG collection and recovery system and destroying collected gases by combustion.

- Operational techniques shall be utilized to control odor sources at the landfill. The size of the working face shall be limited so that the area of waste exposed to the atmosphere is kept to a minimum.

- Solid waste shall be compacted within 1 hour of its arrival at the working face.

- The LFG collection and recovery system shall be installed in phases as each portion of the landfill site is filled. The final system shall contain a network of gas extraction wells, collection system piping, and flaring facilities. Because the LFG generation begins at lower levels of volume and increases during the landfill site life, the gas will be flared initially until sufficient quantities are available for processing into electricity.

- If an odor problem should develop, appropriate control measures shall be implemented. These measures include the application of daily cover material or more frequent application of the cover material to seal the landfill surface, or adjustments to the wells, equipment, and operation of the LFG collection and recovery system.

- To ensure that odors are kept to a minimum, the following odor/LFG monitoring program shall be implemented for the proposed landfill project. The monitoring program shall comply with the requirements of SCAQMD Rule 1150.1 and include the following:

  - Sample Probe Installation: At a minimum of one monitoring per 1,000 feet around the landfill perimeter shall be installed to identify potential areas of subsurface LFG migration. These probes shall be monitored to ensure that large quantities of LFG do not vent offsite through subsurface soils.

  - Integrated Landfill Surface Sampling: The landfill surface shall be monitored to ensure that the average concentration of total organic compounds over the landfill surface does not exceed SCAQMD's standard of 50 ppm.

  - Ambient Air Samples: 24-hour integrated gas samples and required meteorological data shall be taken to assess any impact the landfill is having on the ambient air quality at the landfill perimeter.

  - Instantaneous Landfill Surface Monitoring: Spot checks on the landfill surface shall be made to determine the maximum concentration of total organic compounds measured as methane, measured at any one point on the surface of the landfill does not exceed the SCAQMD's standard of 500 ppm.

  - Regular Monitoring and Annual Testing: LFG concentrations at perimeter probes, gas collection system headers, the landfill surface, and in ambient air downwind of the landfill shall be monitored once per month or less frequently (but no less than quarterly) as required by the SCAQMD. The LFG collection system shall be adjusted and improved based on quarterly monitoring data and annual stack testing results.

- LFG flaring systems shall be sited as required by the SCAQMD and constructed using BACT. The flames shall be totally contained within the stack. Flame arresters shall be provided to the satisfaction of the SCAQMD and City Local Enforcement Agency. To the extent technically and economically feasible, gas recovered at the landfill site shall be converted to energy or developed for other beneficial uses rather than flared.

COUNTY MITIGATION MEASURES

For a discussion of adopted County Landfill mitigation measures, timing, and monitoring responsibilities, with respect to odors refer to Appendix C9, Mitigation Monitoring and Reporting Summary, pp. ~~28-29~~ 24-27, within ~~this~~ the Draft SEIR. Implementation of the proposed project shall require an amendment to this Summary to provide for the development of ±42 acres in the County portion of Sunshine Canyon. The same mitigation measures imposed for the County Landfill project would be adopted for this development in the County. (Refer to Appendix C17, Amended Mitigation Monitoring and Reporting Summary.)

LEVEL OF SIGNIFICANCE AFTER MITIGATION

With the implementation of mitigation measures, no significant odor impacts will occur.

ISCST3 MODEL RUN

Attachment 257

*** OPERATIONAL EMISSIONS - (WITH MITIGATION) W/ FLARES *** 16:53:29
PAGE 1

**MODELOPTs: CONC DDEP RURAL ELEV NOSTD NOBID NOCALM MSGPRO DRYDPL

*** MODEL SETUP OPTIONS SUMMARY ***

**Intermediate Terrain Processing is Selected

**Model Is Setup For Calculation of Average CONCentration Values.
**Model Is Setup For Calculation of Dry DEPosition Values.

-- SCAVENGING/DEPOSITION LOGIC --
**Model Uses DRY DEPLETION. DDPLETE = T
**Model Uses NO WET DEPLETION. WDPLETE = F
**NO WET SCAVENGING Data Provided.
**Model Uses GRIDDED TERRAIN Data for Depletion Calculations

**Model Uses RURAL Dispersion.

**Model Uses User-Specified Options:
1. Final Plume Rise.
2. Not Use Stack-tip Downwash.
3. Not Use Buoyancy-induced Dispersion.
4. Not Use Calms Processing Routine.
5. Missing Data Processing Routine.
6. Default Wind Profile Exponents.
7. Default Vertical Potential Temperature Gradients.

**Model Accepts Receptors on ELEV Terrain.

**Model Assumes No FLAGPOLE Receptor Heights.

**Model Calculates 1 Short Term Average(s) of: 24-HR
and Calculates PERIOD Averages

**This Run Includes: 40 Source(s); 1 Source Group(s); and 1 Receptor(s)

**The Model Assumes A Pollutant Type of: PM10

**Model Set To Continue RUNning After the Setup Testing.

**Output Options Selected:
Model Outputs Tables of PERIOD Averages by Receptor
Model Outputs Tables of Highest Short Term Values by Receptor (RECTABLE Keyword)
Model Outputs Tables of Overall Maximum Short Term Values (MAXTABLE Keyword)
Model Outputs External File(s) of High Values for Plotting (PLOTFILE Keyword)

**NOTE: The Following Flags May Appear Following CONC Values: c for Calm Hours
m for Missing Hours
b for Both Calm and Missing Hours

**Misc. Inputs: Anem. Hgt. (m) = 10.00 ; Decay Coef. = 0.0000 ; Rot. Angle = 0.0
Emission Units = GRAMS/SEC ; Emission Rate Unit Factor = 0.10000E+07
Output Units = MICROGRAMS/M**3

**Input Runstream File: C:\ISC3VIEW\SUNSHINE\SUNSHINE.inp ; **Output Print File: C:\ISC3VIEW\SUNSHINE\SUNSHINE.out

APPENDIX D3

Revisions to Draft SEIR, Appendix B6, Low-Level Health Risk Assessment

INTRODUCTION

A health risk assessment (HRA) was conducted to evaluate the carcinogenic and noncarcinogenic risks associated with toxic air contaminant (TAC) emissions from the Sunshine Canyon Landfill. The risks due to the cumulative emissions from both the "City" and "County" portions of the project were calculated.

The approaches and methodologies used in this risk assessment are from the document entitled, "Air Toxics Hot Spots Program, Revised 1992 - Risk Assessment Guidelines", prepared by the AB 2588 Risk Assessment Committee of the California Air Pollution Control Officers Association (CAPCOA), October 1993. Input assumptions were coordinated with the staff of the South Coast Air Quality Management District (SCAQMD). The CAPCOA procedures for risk assessments from airborne contaminants is the methodology recommended for use by the SCAQMD. All emission estimates used to calculate risk values were from monthly analyses of landfill gas and from periodic emission source tests of the existing flare conducted pursuant to SCAQMD requirements.

Per the requirements of the SCAQMD, the HRA addressed a total of 18 substances on the SCAQMD Rules 1150.1 and/or 1401 lists for the landfill risk evaluation. The substances are listed in **Table 1**. Of the 18 substances, 10 are considered carcinogenic and were evaluated as part of the cancer risk evaluation. The noncancer health effects evaluation addressed 17 of the 18 substances for chronic impacts, and 7 of the 18 substances for acute impacts.

The lifetime carcinogenic risk was estimated for an individual assumed to reside continuously for 70 years at the off-site location of maximum ground-level concentration for the maximum exposed individual (MEI). The chronic and acute health risks were calculated in terms of a "hazard index". This index is calculated by dividing the predicted maximum short- (acute) and long-term (chronic) pollutant exposures by an established safe exposure level called the Reference Exposure Level (REL; CAPCOA, 1993).

Modeling Methodology

Health risks associated with landfill proximity were assumed to derive from landfill gas (LFG) emissions. These emissions result from that fraction of the LFG not collected by the collection/ disposal system, called "fugitive" emissions, plus the small fraction of TACs emitted by the flares. These emissions were used in a computerized dispersion model (ISCST3, Version 97363) to predict the maximum hourly, daily and annual LFG concentrations at the landfill boundary and at the nearest residences and school locations.

Modeling protocols were coordinated with the SCAQMD staff. Meteorological data from the SCAQMD "Newhall" monitoring station was used as the closest and most representative data resource.

A grid of 90 points along the landfill perimeter and 12 Granada Hills residences plus one school (e.g., Van Gogh Street Elementary School) was used to determine off-site exposure to combined flare and fugitive LFG emissions. The off-site grid is shown in **Figure 1**. The residential receptor with the calculated highest concentration of contaminants was analyzed for health risk potential as a worst-case human exposure location. The maximum exposure was determined to be at the residential receptor designated as #50 in **Figure 1**, which is the residence in the community of Granada Hills that would be the most impacted by landfill emissions.

The composition of the gas flare emissions was determined from monthly analysis data of the "raw" LFG entering the existing flare on the "City" portion of the landfill. The maximum number of flares is five flares burning slightly over 20,000 CFM. Over the 70-year risk assessment time frame, the average annual volume generation for LFG emissions will be approximately 60 percent of the highest year based on peak volumes determined from gas generation predictive models or 12,260 CFM. The input parameters for each of the five (5) flares needed during maximum LFG generations were as follows:

Stack Height	=	15.3 meters
Stack Temperature	=	1180° K
Exit Velocity	=	10 m/sec
Stack Diameter	=	3.8 meters
Max. LFG Rate	=	4167 CFM/flare
70-Year Average LFG Rate	=	2452 CFM/flare

The concentration of TACs in LFG was determined from an average of six monthly LFG composition tests conducted from July-December, 1997 by AtmAA, Inc. Flares were assumed to destroy 98 percent of TACs during combustion. Actual measurements of organic gas destruction efficiencies over the last five years have shown better than a 99 percent destruction efficiency. Use of the 98 percent destruction efficiency assumption over estimates the actual flare impact two-fold compared to actual observed flare behavior.

A total of ten percent of all LFG generated was assumed to escape collection.[1] The fugitive LFG was assumed to be uniformly emitted over approximately 2,000,000 square meters (500+ acres) of landfill surface (both City and County areas). The ISCST3 model was run for a unit emission rate (1 g/sec for each flare, 1 $\mu g/m^2$/sec for fugitive area sources). The exposure for each TAC was calculated based upon the ratio of the estimated emission rate to the reference (unit) rate.

Model Results

Output from the ISCST3 model is attached. The maximum exposed individual (MEI) is the residence in the community of Granada Hills located closest to the landfill, and is labeled as #50 in **Figure 1**. The concentration of TACs within the LFG and the maximum estimated ambient concentrations at the MEI are shown in **Table 2**. These predicted concentrations were combined with the appropriate exposure parameters and toxicity data to complete the HRA.

Individual Cancer Risk

Excess cancer risk is calculated by assuming the MEI remains outdoors for 24 hours per day for 365 days per year, for 70 years. While a 70 year exposure assumption is the standard assumption for a CAPCOA health risk assessment, the excessively conservative (over-predictive) nature of this assumption needs to be recognized.

1/ The SCAQMD recommends using a ten percent escape rate for HRA modeling.

Table 3 combines the predicted chronic exposure for 70 years of LFG emissions (1998 - 2068) to predict the excess individual cancer risk at the #50 receptor. The worst-case MEI exposure is 0.96 in one million. A risk of one in a million is considered less than significant. Risks up to ten in a million are considered acceptable if toxics best available control technology (T-BACT) is used to reduce emissions. Flares are considered T-BACT for landfills. The excess cancer risk is thus below the "de minimus" insignificance threshold, and far below the allowable exposure for a T-BACT equipped source. All other receptors have lower exposures than the MEI.

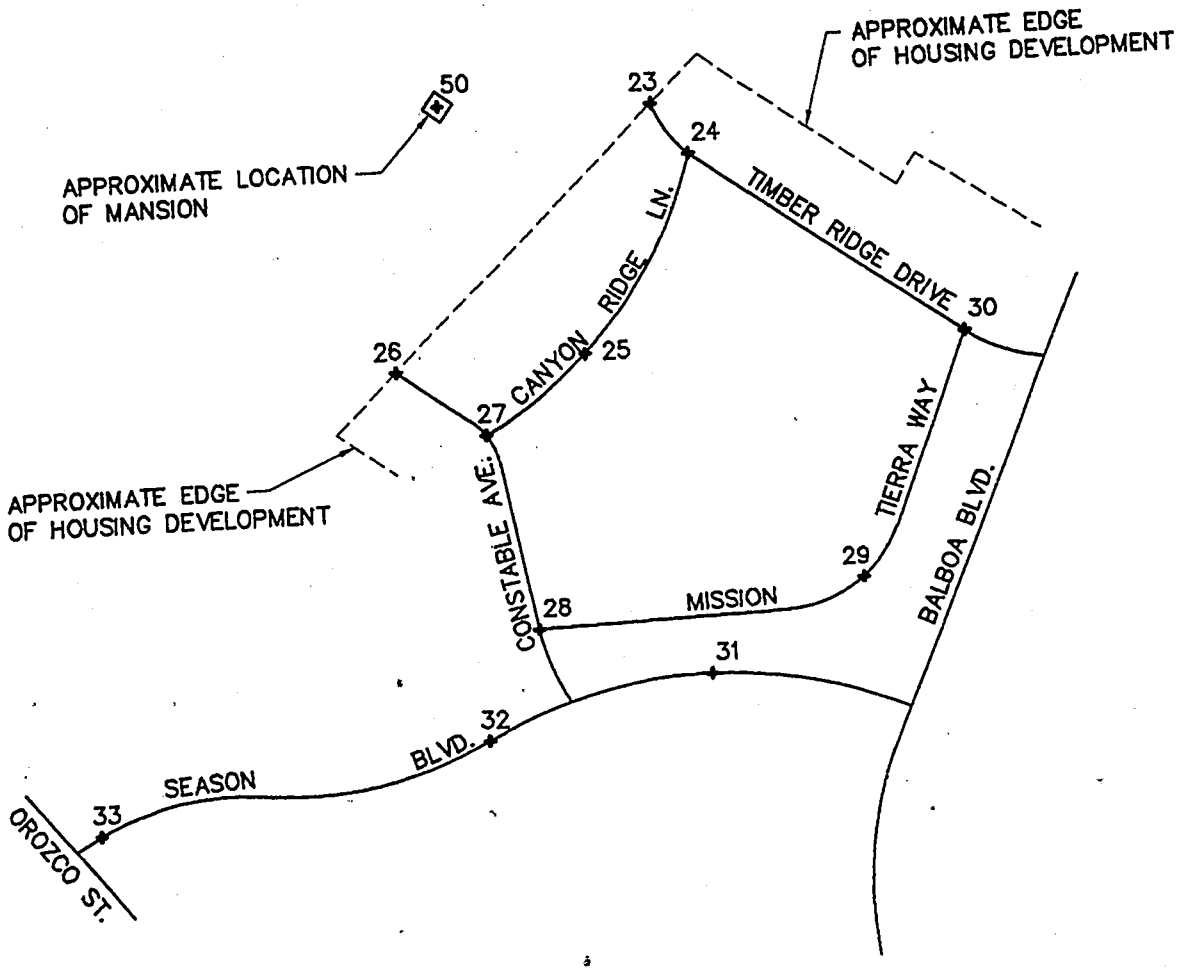
No amount of excess cancer risk is "acceptable" for the person contracting the disease. However, people accrue far higher risks from common daily activities, in comparison to a less than one in a million risk due to landfill proximity. **Table 4** shows the mortality risk from accidents and disasters for the average American. **Table 5** puts the maximum cancer risk in perspective compared to some other risk factors.

Chronic Health Risk

The TACs considered in this assessment are known to potentially affect seven organs/systems in the human body as shown in **Table 6**. Non-cancer effects are calculated through a ratio of the TAC exposure to a published level determined to have no observable health effect (the REL). The sum of all the individual ratios for every identified pollutant emitted by a source is called the health hazard index (HHI). An HHI of 0.5 is considered a potentially significant impact that would require additional analysis. If the HHI is less than 0.5 (below 50 percent of the "safe" exposure level), no additional analysis is necessary. **Table 7** calculates the HHI for any individual target receptor location in the human body. All are well below the significance level of 0.5.

Table 8 compares and combines the HHI for all organs/systems. Although HHI's are not strictly additive, the combined threat to all organs/systems of 0.0113 is well below the 0.5 HHI significance threshold. Accordingly, chronic non-cancer health effects from landfill proximity are less than significant.

Acute Health Hazard



The acute health hazard was similarly calculated as the chronic HHI. **Table 9** shows the acute HHI from the seven compounds with an acute health threat. The acute HHI of 0.1618 is below the 0.5 HHI significance threshold for acute non-cancer health impacts. Therefore, acute health impacts are considered less than significant.

Table 5
LIFETIME CANCER RISK COMPARISON

Risk Source	Lifetime Probability
All types of Cancer	270,000 in 1,000,000
Smoking (1 pack/day)	100,000 in 1,000,000
Medical & Dental X-rays	1,500 in 1,000,000
Living Near a Freeway	1,000 in 1,000,000
Sharing Home with a Smoker	700 in 1,000,000
Saccharin Diet Soda (1 can/day)	600 in 1,000,000
Living in Denver (cosmic rays)	500 in 1,000,000
Peanut Butter Aflatoxin (4 tsp./day)	400 in 1,000,000
Living in a Brick House (radon)	300 in 1,000,000
Proposition 65 Alert Level	10 in 1,000,000
Living Near Sunshine Canyon	<1 in 1,000,000

Table 6
CHRONIC HEALTH RISK TARGET ORGANS/SYSTEMS

Substance	RESP	CNS	G/L	Kid.	Rep.	Imm.	Skin

**MODELOPTs: CONC RURAL ELEV NOSTD NOBID NOCALM MSGPRO

*** MODEL SETUP OPTIONS SUMMARY ***

**Intermediate Terrain Processing is Selected

**Model Is Setup For Calculation of Average CONCentration Values.

-- SCAVENGING/DEPOSITION LOGIC --
**Model Uses NO DRY DEPLETION. DDPLETE = F
**Model Uses NO WET DEPLETION. WDPLETE = F
**NO WET SCAVENGING Data Provided.
**Model Does NOT Use GRIDDED TERRAIN Data for Depletion Calculations

**Model Uses RURAL Dispersion.

**Model Uses User-Specified Options:
1. Final Plume Rise.
2. Not Use Stack-tip Downwash.
3. Not Use Buoyancy-induced Dispersion.
4. Not Use Calms Processing Routine.
5. Missing Data Processing Routine.
6. Default Wind Profile Exponents.
7. Default Vertical Potential Temperature Gradients.

**Model Accepts Receptors on ELEV Terrain.

**Model Assumes No FLAGPOLE Receptor Heights.

**Model Calculates 2 Short Term Average(s) of: 1-HR 24-HR
and Calculates PERIOD Averages

**This Run Includes: 10 Source(s); 3 Source Group(s); and 103 Receptor(s)

**The Model Assumes A Pollutant Type of: PM10

**Model Set To Continue RUNning After the Setup Testing.

**Output Options Selected:
Model Outputs Tables of PERIOD Averages by Receptor
Model Outputs Tables of Highest Short Term Values by Receptor (RECTABLE Keyword)
Model Outputs Tables of Overall Maximum Short Term Values (MAXTABLE Keyword)
Model Outputs External File(s) of High Values for Plotting (PLOTFILE Keyword)

**NOTE: The Following Flags May Appear Following CONC Values: c for Calm Hours
m for Missing Hours
b for Both Calm and Missing Hours

**Misc. Inputs: Anem. Hgt. (m) = 10.00 ; Decay Coef. = 0.0000 ; Rot. Angle = 0.0
Emission Units = GRAMS/SEC ; Emission Rate Unit Factor = 0.10000E+07
Output Units = MICROGRAMS/M**3

WIND SPEED CLASS BOUNDARIES
(MILES/HOUR)

NOTES:
DIAGRAM OF THE FREQUENCY OF OCCURRENCE FOR EACH WIND DIRECTION. WIND DIRECTION IS THE DIRECTION FROM WHICH THE WIND IS BLOWING. EXAMPLE – WIND IS BLOWING FROM THE NORTH 28.0 PERCENT OF THE TIME.

WIND SPEED CLASS BOUNDARIES
(MILES/HOUR)

NOTES:
DIAGRAM OF THE FREQUENCY OF OCCURRENCE FOR EACH WIND DIRECTION. WIND DIRECTION IS THE DIRECTION FROM WHICH THE WIND IS BLOWING. EXAMPLE – WIND IS BLOWING FROM THE NORTH 5.3 PERCENT OF THE TIME.

WIND SPEED CLASS BOUNDARIES
(MILES/HOUR)

NOTES:
DIAGRAM OF THE FREQUENCY OF OCCURRENCE FOR EACH WIND DIRECTION. WIND DIRECTION IS THE DIRECTION FROM WHICH THE WIND IS BLOWING. EXAMPLE – WIND IS BLOWING FROM THE NORTH 4.7 PERCENT OF THE TIME.

WIND SPEED CLASS BOUNDARIES
(MILES/HOUR)

NOTES:
DIAGRAM OF THE FREQUENCY OF OCCURRENCE FOR EACH WIND DIRECTION. WIND DIRECTION IS THE DIRECTION FROM WHICH THE WIND IS BLOWING. EXAMPLE – WIND IS BLOWING FROM THE NORTH 13.9 PERCENT OF THE TIME.

WIND SPEED CLASS BOUNDARIES
(MILES/HOUR)

NOTES:
DIAGRAM OF THE FREQUENCY OF OCCURRENCE FOR EACH WIND DIRECTION. WIND DIRECTION IS THE DIRECTION FROM WHICH THE WIND IS BLOWING. EXAMPLE – WIND IS BLOWING FROM THE NORTH 40.7 PERCENT OF THE TIME.

WIND SPEED CLASS BOUNDARIES
(MILES/HOUR)

NOTES:
DIAGRAM OF THE FREQUENCY OF OCCURRENCE FOR EACH WIND DIRECTION. WIND DIRECTION IS THE DIRECTION FROM WHICH THE WIND IS BLOWING. EXAMPLE – WIND IS BLOWING FROM THE NORTH 16.0 PERCENT OF THE TIME.

WIND SPEED CLASS BOUNDARIES
(MILES/HOUR)

NOTES:
DIAGRAM OF THE FREQUENCY OF OCCURRENCE FOR EACH WIND DIRECTION. WIND DIRECTION IS THE DIRECTION FROM WHICH THE WIND IS BLOWING. EXAMPLE – WIND IS BLOWING FROM THE NORTH 4.8 PERCENT OF THE TIME.

WIND SPEED CLASS BOUNDARIES
(MILES/HOUR)

NOTES:
DIAGRAM OF THE FREQUENCY OF OCCURRENCE FOR EACH WIND DIRECTION. WIND DIRECTION IS THE DIRECTION FROM WHICH THE WIND IS BLOWING. EXAMPLE – WIND IS BLOWING FROM THE NORTH 16.5 PERCENT OF THE TIME.

Solid Waste Facility Inspection Reports:
Inclement Weather Conditions

SUNSHINE CANYON LANDFILL (19-AA-0853)
INCLEMENT WEATHER OPERATION INSPECTION REPORT

INSPECTION DATE: 2/3/98

INSPECTOR: Richard Lange, R.E.H.S. III

VIOLATIONS: None observed at the time of inspection

AREAS OF CONCERN: None observed at the time of inspection.

Title 27 California Code of Regulations (CCR)

COMMENTS:

1. **20540-Roads** - Roads were kept in a safe condition and maintained such that vehicle access and unloading could be safely conducted during inclement weather. Tracking of material onto adjacent public roads was minimized.

2. **20580-Lighting** - Adequate lighting was provided.

3. **20590-Personal Health and Safety** - Operating and maintenance personnel were wearing health and safety equipment appropriate for the inclement weather.

4. **20615-Supervision** - Adequate supervision of a sufficient number of qualified personnel were on site to insure proper operations.

5. **20630-Confined Unloading** - Unloading was adequately confined.

6. **20640-Spreading/Compacting** - Spreading and compacting were accomplished as rapidly as practicable in layers with repeated passages of the landfill equipment.

7. **20650- Grading of Fill Surfaces** - Covered surfaces of the disposal area were graded to promote lateral runoff of precipitation and to prevent ponding.

8. **20740-Equipment** - Equipment was adequate in type capacity and number.

9. **20750**-Site Maintenance - Deteriorated or defective conditions were monitored and promptly repaired.

10 **20820-Drainage/Erosion Control** - The drainage system functioned satisfactorily maintaining the integrity of roads, structures, gas monitoring and control systems. No safety hazard or exposure of waste was observed at the time of inspection.

INSPECTOR: Richard Lange, R.E.H.S. III

VIOLATIONS: None observed at the time of inspection

AREAS OF CONCERN: None observed at the time of inspection.

Title 27 California Code of Regulations (CCR)

COMMENTS:

1. **20540-Roads** - Roads were kept in a safe condition and maintained such that vehicle access and unloading could be safely conducted during inclement weather. Some mud was observed at entrance on San Fernando Rd which appeared to have come from the washout of a freeway slope at the Balboa exit. Work was in progress by BFI personnel to remove the mud from in front of the landfill entrance.Tracking of material onto adjacent public roads was minimized.

2. **20590-Personal Health and Safety** - Operating and maintenance personnel were wearing health and safety equipment appropriate for the inclement weather.

3. **20615-Supervision** - Adequate supervision of a sufficient number of qualified personnel were on site to insure proper operations.

4. **20630-Confined Unloading** - Unloading was adequately confined.

5. **20640-Spreading/Compacting** - Spreading and compacting were accomplished as rapidly as practicable in layers with repeated passages of the landfill equipment.

APPENDIX D7

USEPA Letter to Dr. G. Fred Lee (February 9, 1998)

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
WASHINGTON, D.C. 20460

FEB 9 1998

OFFICE OF
SOLID WASTE AND EMERGENCY
RESPONSE

Dr. G. Fred Lee
G. Fred Lee & Associates
27298 E. El Macero Dr.
El Macero, California 95618-1005

Dear Dr. Lee:

Thank you for sharing your thoughts on the Municipal Solid Waste Landfill Criteria issued by the Environmental Protection Agency (EPA) in October 1991. After spending considerable time reviewing and discussing your letters and reference materials, we believe that we have fundamentally different approaches to landfill performance. Such philosophical differences make comparisons between our approaches impractical.

While you contend that landfills will always be a threat if they release any constituent, we believe that controlled releases of certain constituents from landfills may be acceptable provided the releases do not exceed regulatory levels that have been established to protect human health and the environment. Our risk assessment supports our position. It concludes that disposal of municipal waste in properly located, designed, operated, closed, and monitored landfills poses very low risks to human health and the environment. For a complete discussion of our risk findings, please see 56 FR 50984-8, October 11, 1991.

We believe that our regulations satisfy the statutory intent to protect human health and the environment. However, we want to stay abreast of any new developments in landfill technology that may help us further explain our position and allay any lingering doubts about municipal solid waste landfill safety. To do this, we plan to publish a series of fact sheets in the near future on such topics as liner longevity, leachate recirculation, consequences of liner leakage, and landfill management beyond the regulatory 30 year post-closure care period. Given your interest in these issues, we are hoping that you would be able to share relevant data on these topics. You may send any pertinent information to Allen J. Geswein, P.E. of my staff at U.S. EPA, Office of Solid Waste (5306W), 401 M St., S.W., Washington, DC 20460.

Recycled/Recyclable • Printed with Vegetable Oil Based Inks on 100% Recycled Paper (40% Postconsumer)

Again, thank yc ,l for your thoughtful analysis of our approach to regulating municipal solid waste ndfills. Please feel free to contact Mr. Geswein at 703-308-7261 if you w int to discuss this issue further.

Sincerely yours,

Robert W. Dellinger, Director
Municipal and Industrial Waste Division

Mr. Joe Maturino, REHS
Environmental Affairs Department
201 North Figueroa Street
Los Angeles, California 90012

Dear Mr. Maturino:

On Wednesday, February 4, 1998, I accompanied Mr. Tseng, yourself and a member of the City Council office on a helicopter ride to inspect the area surrounding Sunshine Canyon, Porter Ridge and O'Melveny Park to determine if it is possible to design a mountain bike trail, hiking/horse trail, on Browning-Ferris Industries owned property (known as Sunshine Canyon Landfill). Our findings are as follows:

1. Unsafe due to severe slopes.
2. Additional staff needed.
3. Fire clearance maintenance.
4. Maintenance of trails.
5. Material costs, soil, erosion due to heavy rain.
6. Trails, dead-end, trails would not serve a purpose to the community.

On Tuesday, February 10, 1998, I met with you, David Thompson, and Eugene Tseng, in my office at the Valley Region Headquarters to discuss all the possibilities to construct a recreational trail. Our Department concluded, that the recreational trail would not be practical at this time. If you have any questions regarding this matter, please call me at 818/756-8190.

Very truly yours,

JAMES N. WARD

MAY 18 1998
ULTRASYSTEMS
ENVIRONMENTAL

I am in receipt of a facsimile of a letter dated March 3, 1998 from Department of Recreation and Parks Senior Park Maintenance Supervisor Ron Berkowitz to your Office. This letter addresses findings of Recreation and Parks regarding the potential for recreational use of the Sunshine Canyon landfill site. In this letter Mr. Berkowitz notes that after inspecting the property from the air, and after discussing the potential of the property for use as a bike trail, hiking/horse trail, the Department of Recreation and Parks has concluded that a recreational trail would not be practical at this time. The reasons for said conclusion are delineated in that letter.

I understand the reason for these findings at the present time, and concur that a recreational trail that is unsafe would not be appropriate. Implicit in any recreational use of the property is the understanding that it be undertaken only if it is safe to do so. I believe, however, that the long held concept of developing some recreational use of this area should not be abandoned prematurely. The Planning Department will reserve the option to reevaluate the use of the property for recreational purposes at a later time after completion of the closure activities (during the post-closure maintenance period) of the County portion and/or after the closure of the City portion of Sunshine Canyon Landfill if any proposed expansion is permitted.

We take this position now because of the reasons listed in the Department of Recreation and Parks letter and because of the following:

1. The need to complete closure of the current City portion of the Sunshine Canyon Landfill;

2. The future recreational needs and the potential for the availability in the future of resources for trail development, operations and maintenance, and;

3. The impact of current operations and/or potential future operations.

For the purposes of the current closure of the City portion of the Sunshine Canyon Landfill, Condition no. 14 of ZA Case No. 17804 may be considered conditionally satisfied at this time but only until such time as a reevaluation of the site for the provision of recreational opportunities is conducted during the post closure maintenance period.
